INDEX TO VOLUME XCVI, FROM JANUARY TO JUNE, 1908.

MINING AND SCIENTIFIC PRESS

A

PAGE.

Accident—Alpha Shaft 260
A Curious.....Earl C. Cleaveland.... 387
Accidents, Railroad 207
Accommodations for Employees.....E. P. Kennedy.... 453
Accounts for the Superintendent, Mine.....Algernon Del Mar.... 454
Accumulation and Absorption of Gold Amalgam by Copper Plates 806
Acid-Resisting Alloy 700
Act, Canadian Industrial Disputes....Frank A. Ross.... 104
Actual Situation of Copper.....James Douglas.... 7
Adaptation of a Steam-Driven Compressor to Water-Power.....Horace G. Nichols.... 230
Advice to Mining Students.....J. H. Collins.... 638
Affairs in San Francisco.....Editorial.... 719
Ainsworth New Theodolite..... 434
Air-Compression, Simple Problems in.Edward A Rix.... 394
Pressure Pumping, Westinghouse Direct..... 819
Rock Penetration by.....J. P. K.... 520
Alabama Gold Mines.....266, 780
Alaska.....Alfred H. Brooks.... 20
Cassiterite in 253
Mining in the Wrangell District..... 199
Progress in Southeastern..... 133
The Copper River District (I, II).....W. M. Brewer....71, 101
Allen, Alfred.....Concerning Superintendents.... 229
Allentown Electric Pump..... 368
Allis-Chalmers Suspended Iron Frame Vanner..... 399
Alloy, Acid Resisting..... 700
Alpha Shaft Accident..... 260
Alpine and American Tunnel Records..... 781
Aluminum in Steel..... 450
Amalgam 384
By Copper Plates, Accumulation and Absorption of Gold 806
Amalgamated Report and Copper Costs...Editorial.... 823
Amalgamation 350
Ditto .....D. M.... 452
Cyaniding Mill Pulp After.....Cyril E. Parsons.... 660
American Tunnel Records, Alpine and..... 781
Spiral Pipe Connections..... 679
Switching Locomotive 751
Anaconda, Two Copper Mines.....Editorial.... 141
Analysis of Production of Two Great Copper Mines..... 160
Antimony Ore in California.....J. Henry Rickard.... 558
Price of 286
Apparatus, Life-Saving.....W. E. Wingramm.... 770
Appelbaum, Misha E.....The Outlook for Copper.... 76
Archbold, T. R.....Psychology of Mining Booms.... 319
Argall, Philip.....Rock Oxidation at Cripple Creek.... 883
Arnold, C. Everard.....Method of Mining.... 495
Arrival of the Fleet.....Editorial.... 610
Artesian Basins 710
Assay, Copper.....E. L. Larison.... 483
Ditto.....E. R. Rice.... 319
Furnace, Gasoline Connections for.H. W. Cuming.... 697
Statements, Misleading.....Engineer.... 521
Value of Mill Products and Smelter Contracts, Relation Between.....Gelasio Caetani.... 25
Values, Standardization of Bullion and..... 878
Assaying Battery Chips..... 712
Braun Electrolytic 206
With Pan 222
Assessment Work 253, 318
Work, Road Work for..... 286
Assisting Graduates .....Editorial.... 49
Association, The New.....John B. Hastings.... 558
Work for the Miners'.....Editorial.... 304
Atlas Bottom Delivery Electric Charging Car..... 643
Scale Charging-Car 174
Auriferous Gravels of Sierra Nevada..... 350
Austin, L. S.....Heat of Fusion of Silver-Lead Blast-Furnace Slag 566
Ditto.....Lake Superior Ore-Dressing Practice.... 259
Ditto.....Smelting in Globe in 1893.... 196
Ditto.....Treatment of Sulphide Ores by the Huntington-Heberlein Process 611
Ditto...Welfare of Laborers in Reduction Works.... 189

B

Bain, H. Foster....Leasing the Federal Coal Lands.... 73
Banking, Mexican .....Editorial.... 755
Barytes 553
Battery Chips, Assaying..... 712
Battleship, From Mine to.....T. A. Rickard.... 622
Bauxite 553, 589
Bayles, L. C.....Drill Contest on the Rand.... 592
Becker, Arnold.....Depth at Goldfield.... 62
Ditto.....Geological Possibilities at Goldfield.... 846
Behrend Concentrator 679
Belt Lacing, Bristol Metal..... 302
Bering Sea, Recent Volcanic Eruptions in.....Arthur S. Eakle.... 353
Bernewitz, M. W. von..Water Supply for Kalgoorlie.... 709
Biographical Note .....Editorial.... 272
Ditto.....William G. Devereux.... 387
Black Sand, Separation of Platinum..... 253
Blast-Furnace, Drying Air for..... 232
Blue Book, Professional.....Editorial.... 209
Bogus Promoters.....H. F. M. Crookshanks.... 802
Bohn, C. A.....Mexico, Progress in 1907.... 43
Bolivia, Burma, and Chile, Recent Mining Wanderings in.....J. H. Curle.... 879
Booms, Psychology of Mining.....T. R. Archbold.... 319
Ditto..... Conservador.... 590
Ditto.....J. H. Curle.... 8
Ditto.....Claude Sachs.... 156
Bore-Hole, Deepest 225
Bore-Holes, Deviation of.....Joseph Kitchin.... 462
Surveying 222
Boss, M. P.....Crushing Ore.... 354
Boston Consolidated Mill..... 234
Bottom Delivery Electric Charging-Car, Atlas..... 643
Boursin, Henry.....Puddling a Wet Shaft.... 127
Braun, Electrolytic Assaying..... 206
Brewer, W. M.....The Copper River District Alaska (I, II).....71, 101
Brewster, T. J....Electric Furnace in Zinc Smelting.... 801
Bristol Metal Belt Lacing..... 302
Brittain, Doss....Mining Costs in the Joplin District.... 526
Broken Hill, Flotation Processes at..... 491
Brooks, Alfred H.....Alaska.... 20
Brown, Joseph Rodney.....El Oro Tube-Mill Lining.... 289
Brush as Fuel in Roasting, Use of....Arthur C. Nahl.... 123
Bucket Elevator, Novel.....P. R. Whitman.... 850
Bullock, L. N. B.....Cyanide Practice at Copala.... 63
Bureau, National Mining.....165, 228
Ditto .....Editorial.... 208
Ditto.....Geo. Otis Smith.... 258
Of Mines 102
Ditto .....Editorial.... 577
Of Mines, Federal.....Editorial.... 79
State Mining .....Editorial.... 176
Burma, Chile, and Bolivia, Recent Mining Wanderings in.....J. H. Curle.... 879
Burning Liquid Fuel Without Steam or Compressed Air.....Robert Schorr.... 851
Butte, Montana, Earth Movements at.R. H. Chapman.... 493
Butters Cyanide Plant at San Juancito, Honduras.....G. L. Guthrie.... 810
Butters, Henry A.....Stock Companies and Company Promotion 597
By-Laws of the Institution.....Editorial.... 238

PAGE.

C

Cadmium 222
Caetani, Gelasio.....Relation Between the Assay-Value of Mill Products and Smelter Contracts..... 25
Cages, Skips and.....S. A. Worcester.... 486
Caldecott, W. A.....Cyanidation of Ore Containing Both Coarse and Fine Gold..... 734
Ditto.....Cyanidation of Silver Ore in Mexico (I, II) 426, 594
California.....Charles G. Yale.... 14
Antimony Ore in.....J. Henry Rickard.... 558
Minerals.....Arthur S. Eakle.... 98
Primary Chalcocite in.....Oscar H. Hershey.... 429
The Smelter of the Mammoth Copper Mining Company at Kennett.....Donald F. Campbell.... 30
Calorimeter, A Simple..... 636
Calumet & Hecla, Two Copper Mines.....Editorial.... 141
Campbell, Donald F.....A Handy Tramway.... 675
Ditto.....Mine Fires.... 483
Ditto.....The Smelter of the Mammoth Copper Mining Company, at Kennett, California..... 30
Canadian Industrial Disputes Act....Frank A. Ross.... 104
Canvas Pipes 526
Capitalization of Rand Mines....Thomas H. Leggett.... 64
Capitalizing Equipment.....Edward Walker.... 451
Car, Atlas Bottom Delivery Electric Charging..... 643
Handy .....E. McCormick.... 331
Carat Weight.....E. J. Vallentine.... 602
Carpenter, Franklin R.....Mine Fires.... 697
Carson City, Nevada, A Tertiary River Channel near..... .....John A. Reid.... 522
Carter, E. E..Churn-drill as a Means for Prospecting.... 572
Cassiterite in Alaska..... 253
Cement, Portland 170
Central Nevada.....A. H. Elftman.... 398
Chain Links, Strength of..... 781
Chalcocite in California, Primary..Oscar H. Hershey.... 429
Chamberlin, T. C.....The Fault Problem.... 172
Chance, H. M.....Mining and Metallurgical Society of America..... 698
Channing, J. Parke...Copper Smelting in Tennessee.... 97
Chapman, R. H.Earth Movements at Butte, Montana.... 493
Charging-Car, Atlas Scale..... 174
Chile, Bolivia, and Burma, Recent Mining Wanderings in.....J. H. Curle.... 879
China, Mining Regulations in..... 298
'Chinaman' Ore-Chute 667
Chrome-Steel Cone-Head 643
Churn-Drill as a Means for Prospecting.E. E. Carter.... 572
Civilization, A Tribute to.....Editorial.... 48
Claims in Mexico, How to Acquire Title to Mining..... 331
Cleaning Mercury 695
Cleaveland, Earl C.....A Curious Accident.... 387
Clown and the Hippodrome.....Editorial.... 436
Coahuila, Coal in.....Ezequiel Ordonez.... 363
Coal Consumption 423
Cutter for Room and Pillar, Shortwall..... 892
In Coahila.....Ezequiel Ordonez.... 363
Lands, Leasing the Federal.....H. Foster Bain.... 73
On Pacific Coast..... 432
Cobalt.....Frank C. Loring.... 96
Ontario.....H. B. Smith.... 876
Code, Philippine Mining.....Editorial.... 683
Coeur d'Alene, Labor Conditions in the.....J. P. K.... 192
Milling in the.....George Huston.... 232
Colbath, James S.....Iron Screen in Zinc-Boxes.... 123
Colemanite 318
Collecting Statistics, Method of.Waldemar Lindgren.... 14
College Instructors.....Walter E. Koch.... 194
Ditto.....John A. Reid.... 93
Collins, Edgar A.....Cyanidation in Nevada....63, 257
Collins, J. H.....Advice to Mining Students.... 638
Colorado .....Forbes Rickard.... 65
Historical Development of.....T. A. Rickard.... 295
Combustion 496
Company Promotion .....Editorial.... 575
Promotion and Stock Companies..... .....Henry A. Butters.... 597
Comparative Crushing Experiment by Rolls and Ball Mill 572
Tests of Shoes and Dies..... 493
Compressor to Water-Power, Adaptation of a Steam-Driven.....Horace G. Nichols.... 230
Comstock, Recent Work on the...Walter D. O'Brien.... 804
Concentration.....Algernon Del Mar.... 225
By Flotation 773
Concentrator, Behrend 679
A Make-Shift 589
Concerning Promoters.....Tom L. Gibson.... 451
Rawhide .....Editorial.... 436
Superintendents .....Alfred Allen.... 229
Ditto.....C. R. G.... 485
Concrete House, Poured..... 532

PAGE.

Cone-Head, Chrome Steel..... 643
Conical Tube-Mill.....H. W. Hardinge.... 223
Conservative Finance .....Editorial.... 647
Constitution and By-Laws of Mining and Metallurgical Society 603
Consumption of Power in Mill..... 286
Contracts, Relation Between the Assay-Value of Mill Products and Smelter.....Gelasio Caetani.... 25
Control, Railroad .....Editorial.... 786
Convenient Small Steam Hammer..... 855
Conveyor 416
Co-operation in Mining and Geology....U. S. Grant.... 333
Copala, Cyanide Practice at.....L. N. B. Bullock.... 63
Copper, Actual Situation of.....James Douglas.... 7
Assay.....E. L. Larison....483
Ditto.....E. R. Rice.... 319
Belt of the Sierra Nevada, Foothills..... .....Oscar H. Hershey.... 591
Ditto.....John A. Reid.... 388
Deposits in the Western Foothills of the Sierra Nevada.....William Forstner.... 743
From Cupriferous Waters, Precipitation of..... .....Frank H. Probert.... 27
Mines, Analysis of Production of Two Great..... 160
Mines, Two .....Editorial.... 141
Mining Methods, Michigan.....Lee Fraser.... 847
The Outlook for.....Misha E. Appelbaum.... 76
Production 100
Ditto .....Editorial.... 239
The Production of.....L. C. Graton.... 102
River District, Alaska (I, II)....W. M. Brewer....71, 101
Simultaneously, Refining and Shaping..... 674
Smelting in Tennessee.....J. Parke Channing.... 97
Core-Drill, New Type..... 334
Cornish Pumps of New Design.....E. P. Jones.... 94
Ditto .....Old Timer.... 592
Correction.....Arthur DeW. Foote.... 195
Corrected.....C. H. Shaw Pneumatic Tool Co.... 322
Cost of Dredging..... 525
Of Mining 518
Of Sinking 332
Costs, Cyanide.....W. A. Moulton.... 803
In the Joplin District, Mining.....Doss Brittain.... 526
Timber and Mine.....Editorial.... 504
Variations in Mining.....Algernon Del Mar.... 156
Ditto.....J. R. Finlay.... 22
Ditto.....John B. Hastings.... 420

Greeting!

ONCE A YEAR it is pleasant to drop the thin anonymity of the nebulous 'We' and assume the intimately personal tone of the singular pronoun. I confess to a belief in a journalism that can be human as well as technical, that can be vital as well as scientific and, to speak frankly, I have no liking for periodical literature when its sole purpose is to serve as a lure for advertising. Something more than paper and printer's ink are needed. Character counts, for good or ill, in the making of a technical journal as in any other form of human endeavor. The MINING AND SCIENTIFIC PRESS has lived for 47 years because it has received the momentum given to it by dynamic men, by Alfred T. Dewey, Charles G. Yale, Alfred Holman, and J. F. Halloran in the past, and more recently by a group of men, some of whose names appear in the adjacent column. The inventions of Mergenthaler and Lanston have done wonders for the rapid multiplication of the written word, but all the automatic devices of mechanical genius cannot eliminate the value of the personal equation. It is the men behind the pulp that make the press, whether it be a yellow newspaper or a scientific review. And in no branch of periodical literature is this so evident as in that which mirrors the thoughts and deeds of the engineer. For the engineer is very much of a man, he is the least emasculated of the products of an advanced educational program and he vibrates to all the wireless pulses of his time and place. The discussion of civic duties and of professional ethics is as much the province of a technical journal as is the consideration of the best method of stoping or the cheapest way to erect a stamp-mill. Man does not live by bread alone. The training of clever men without any civic spirit, the development of young engineers adapted to winning big salaries, the digging of gold to make men rich—these are not the only purposes either of the universities or of those more instant mediums of instruction that take the form of newspapers. Such at least has been the idea underlying much of the matter that has appeared in these pages during 1907, and I speak, of course, not for myself alone but for a number of contributors. The columns of this journal have been honored during the past twelve months by the writing of such educators—using the word in its widest sense—as Rossiter W. Raymond, S. F. Emmons, James F. Kemp, James Douglas, and Courtenay De Kalb. In the furtherance of the application of geology to mining, of chemistry to metallurgy, and of good sense to both, there have appeared articles by James W. Abbott, L. S. Austin, Philip Argall, G. F. Beardsley, F. L. Bosqui, C. B. Brodigan, F. W. Bradley, Ross E. Browne, Charles Butters, W. R. Crane, J. H. Curle, Edgar Collins, J. R. Finlay, William Forstner, E. M. Hamilton,

F. Lynwood Garrison, Hiram W. Hixon, Ernest A. Hersam, Alfred James, Carlos W. Van Law, Thos. H. Leggett, Walter McDermott, Ben B. Lawrence, W. J. Loring, Waldemar Lindgren, James W. Neill, A. R. Parsons, John A. Reid, Thomas T. Read, H. W. Turner, and H. V. Winchell—in fact, a list of names that if given in full would read like a directory of the profession. If the MINING AND SCIENTIFIC PRESS has made progress in 1907—and I am proud to know that it has—the result is due to the generous support of a number of men possessed of a noble generosity, namely, the willingness to give, from the treasury of experience, the information and advice that money does not buy. Gentlemen, I thank you. 1907 closed amid a financial stringency no less astringent to this journalistic enterprise than to any other commercial undertaking, but the new year brings the assurance of progressive improvement and enlarged usefulness. It is my purpose to make this paper the spokesman for the profession of mining engineering; our columns are open to the free discussion of topics pertaining to the life and work of the engineer, the geologist, and the chemist, all of whom contribute their part to the development of the mining industry; it will be my pleasure to give publicity to opinions contrary to my own, always provided that they are expressed in good faith; it will be my aim to avoid taking sides in industrial quarrels, believing that a paper such as this should be just rather than partisan; in fine, it is my hope to develop the MINING AND SCIENTIFIC PRESS along the lines of an unattainable ideal—a paper useful to many and injurious to none.

T. A. RICKARD.

January 1, 1908.

WE TAKE PLEASURE in announcing that Mr. Edward Walker is now our representative at London. His office will be in Salisbury House, which is the headquarters of many members of the mining profession. We invite our English readers to keep in personal touch with Mr. Walker, who will be glad to receive suggestions likely to make this journal increasingly interesting and usefut to all those engaged in metal mining.

IN A POSTSCRIPT appended to our last issue, we notified our prospector friends that the bill for remitting the assessment work due on mining claims had not passed the Congress of the United States. It was approved by the Senate, but failed to reach the House of Representatives before adjournment for the holidays. It is stated that the Commissioner of the Land Office is opposed to the bill, and it is doubtful whether it will be passed when the Congress meets again during January. This failure to remove the obligation to perform $100 worth of work on each location will go hard on mining companies controlling a large number of claims on which stock has been issued and financial operations have been based, but it will hurt very few genuine prospectors.

WE LEARN from a friend that at Manhattan, Nevada, they read only Debs' *Appeal to Reason* and the San Francisco *Examiner*. Note the association. Do they give club rates for these two highly intellectual, refined, patriotic, and noble examples of modern literature? We are reminded of the fact that at a Denver meeting of sympathisers with Haywood, Moyer, and Pettibone, Mr. Eugene V. Debs was introduced by the chairman thus: "I, who expect to be in jail, introduce to you a man who has been in jail, who will speak to you in behalf of a man who is now in jail." This introduction needs editing; it ought to read: "I, who expect to be in jail introduce to you, *who ought to be in jail*, a man, etc." To return to Manhattan, if Debs and Hearst are the literary purveyors to that mining camp, we do not wonder that its boom has busted. The people of Manhattan had better improve their reading by getting Kemp on 'Ore Deposits' and Richards on 'Ore Dressing.'

AMONG THE ARTICLES in this issue is one by Mr. Alfred James. This cyanide specialist is in the habit at the end of each year of sending a circular letter to his brother practitioners and in his Epistle to the Cyaniders he summarizes the progress of the art that is symbolized by KCy. It is fair to say that these *obiter dicta* of Mr. James have a special value in that they are the expression of his personal opinion. For instance, his remarks concerniug filter-pressing devices should not be deemed offensive by the inventors or owners of other machines of the same type, for Mr. James is interested in the manufacture of the Ridgway filter and is pardonably partial to this clever invention. For the rest, anything written by so well informed an authority is sure to be interesting to our readers, for he has two qualities essential to useful writing—knowledge and sincerity.

NOTHING could be more timely than the article on mining booms by Mr. J. H. Curle, for we happen just now to be at the end of one period of excessive speculation and in a mood to listen to the moralist. Mr. Curle's contribution is characteristic; in the first place, it was posted at Colombo, in Ceylon, when the writer was on his way to Burma, and thus illustrates the nomadic activity that has made him so well informed concerning mining all over the world; secondly, it is written with the frank fearlessness that makes all his writings so effective. He is sometimes wrong, but never insincere; he is sometimes injudicious (in the eyes of a critic less friendly than the MINING AND SCIENTIFIC PRESS), but he is never the catspaw of a capitalist. There are not many men that can afford to be so independent of speech and so outspoken in criticism. Mr. Curle has followed his own advice in mining matters and has made money. This gives force to what he has to say and makes it less necessary for him to modify his remarks to suit the purposes of high finance and low promotion. Naturally, it is a pleasure to publish such an article as 'Psychology of Mining Booms' in our columns, for we are in accord with the tenor of his preachment. That booms are hurtful to legitimate mining, that mining is a speculation and not an investment, that directors ought to be trustees, that titled figureheads (whether a governor of Nevada or an Earl of Chesterfield) are mere lures to a deluded public, that mining engineers should

not gamble in mining shares—these are all unpalatable truths the recognition of which it is our province to enforce. Mining is an industry based upon the application of science, which is in itself only highly organized common sense; science is based on facts and on correct reasoning from facts; make-believe has no place in science and therefore none in mining.

CHRISTMAS is always celebrated in a pleasant way by the managers and men of the North Star mine, at Grass Valley, California. It is the custom for the company to give to each employee a gold coin, either a $5 or a $10 piece, fresh from the San Francisco mint. Mr. A. D. Foote, the manager, makes a pleasant speech, thanking the men for their co-operation and expressing the good wishes suited to the occasion. This is followed by refreshments, served in a prettily decorated room. Carols and speeches then ensue, and the general effect is to promote goodwill all round. Such was the case last week and we hope that it may happen with unbroken regularity for a hundred years to come.

NO ENDORSEMENT of the article by Mr. J. R. Finlay is needed; both the subject and the writer will commend themselves to practical men. Assuredly the comparative table of working costs, the preparation of which must have involved a great deal of work, will prove most suggestive to those in charge of mines. The inferences made by Mr. Finlay are open to discussion and we shall be glad to publish the views of other engineers on this vital subject. It is quite certain that the fundamental truths dug out of such statistical data are highly educating, in that they lead us to appreciate the factors dominating the financial success of mining operations. Mr. Finlay's experience in the copper and iron regions, followed by contact with actualities in Colorado and Idaho, gives him a strong grasp of the essential problems faced by the mine operator, and other engineers can pay him no better compliment than to discuss the points that he has elucidated.

DURING 1907 the affairs of the American Smelting & Refining Company passed through a crisis from which they have, we hope and believe, been successfully extricated. But those controlling this important industrial enterprise have made one blunder, the mention of which is timely. We do not refer to the fact that the Guggenheims have bitten off financially rather more than even this clever family is able comfortably to assimilate, nor do we refer to the stock gambling operations in which they have become, from time to time, involved; we refer particularly to the blunder, curious in a race marked by business sagacity, of trying to combine the executive and financial management with technical work. To speak plainly—and it is the only way worth anything—the Guggenheims are ambitious of being as expert in mining and metallurgy as they are skilled in the financial operations incident to the industry in which they have become so potent a factor; they want to be mining engineers and smelters, as well as financiers, as if to say: "We pay enormous salaries to these professional men; why should not we, or our sons, acquire the requisite technical training and so become independent of expert advice from outside the family." At least, this is how it looks to those at a distance, to whom the doings of the smelter people are at least as interesting as the performances of the Shah of Persia or the Russian douma.

Reports of Mining Companies.

THE beginning of another year renders it opportune to review the sources from which the world derives the gold that is both the standard of value and the great lubricant of commerce. Such a review will be found elsewhere in this issue. Any attempt to compile a trustworthy tabulation of the yield of individual mines in widely scattered regions develops the fact that the information so interesting to the public and so necessary to shareholders is furnished in a fashion as varied as the climates and clothes characterizing the localities in which gold mining obtains. In the premier goldfield of the modern world—the Transvaal—the Chamber of Mines obtains details of production from each operating company and publishes the information at the close of every month, so that exact data are available. But the periodical reports furnished by the South African companies are severely restricted to a statement of facts accomplished, there is rarely any account of developments underground and it is only at the annual meetings, as a rule, that shareholders learn much regarding future prospects. In consequence, while the financial houses controlling groups of mines are kept informed concerning the fluctuating value of the mining speculation that is represented by each mine, the small shareholder is in the dark and takes the chances of a blind pool dominated by clever financiers. At one time it was supposed that the mines of the Rand were fixed investments superior to the ordinary vagaries of gold veins and therefore there could be nothing particular to tell the shareholders save the chronicles of production. But this is a fallacy that has been exploded long ago and the iridescent films of the bubble lie scattered all over Throgmorton Avenue. The disillusionment is one of the reasons why the share market in South Africans is depressed, for, apart from the interminable labor troubles, the ordinary shareholder never knows when the quotation on his stock may drop suddenly, to learn subsequently that an unexpected change in the grade of the ore in one part of the mine, or an error in former estimates, or a structural disturbance due to a dike, has lessened the value of his mine and greatly diminished its earning capacity. Such untoward episodes are infrequent, but the unpleasantness of them is intensified by the absence of a frank statement, at regular intervals, concerning the developments affecting the life of the mine. Thus the typical South African company gives beautiful monthly and quarterly statistics and considers that enough. On the other hand, many American mines publish annual or semi-annual reports and, for the rest, they tell the minority shareholder that he has no particular reason for existing. Naturally, annual reports are not of much use to the

holders of stock in an investment so speculative as a mine, the value of which fluctuates weekly more than the amount of the dividend. Here also the shareholder, being in the dark, becomes a gambler against his will, for the uncertainties are needlessly multiplied. Finally, there are groups of mines controlled by financial houses and engineering firms that really act as trustees for the shareholders, whether large holders or small ones, and furnish all the information compatible with businesslike methods. The Indian mines managed by John Taylor & Sons, the Western Australian group directed by Bewick, Moreing & Co., and the Mexican companies controlled by the Exploration Company, are excellent examples of the better tendencies of modern mine management. Monthly reports of output, cost, and profit are given promptly, by cablegram, and these are followed by a detailed description of the developments underground, the nature of new discoveries, and the prospects at each level. Then, at the end of the year, a complete review of progress is given to the shareholders, together with an analysis of the work done and a fresh estimate of the ore reserves, accompanied usually by a luminous speech by a chairman of the type of Edgar Taylor or R. T. Bayliss, who is no figure-head, but a financial-mining authority of wide experience. Such proceedings give dignity to the business of mining and emphasize the proper status of the industry.

Another factor rendering comparisons occasionally unfair is due to methods of accounting. In the case of some West Australian mines, it is found that a lordly profit wilts away when 'depreciation' and 'development' are deducted. In such instances the 'gross profit' is magnified by treating 'depreciation of plant and machinery' as no part of the mining expense; even 'shaft sinking and development work' are put down as extras, instead of being vital necessities—as vital to a mine as ploughing to a farm. Machinery is debited to capital account as if it were everlasting and in blind disregard of the fact that when once the mine is worked out, the machinery is just so much scrap. But in these respects the business of mining has improved immensely; we have traveled far since the days when a false air of prosperity was given to a mining enterprise by treating timbers underground as capital invested; by considering machinery, even drills and other appliances subject to excessive wear and frequent repair, as fixed property; by regarding cross-cuts, nay, even a working level, as an item of development that bore no relation to current expense; and so forth. The one paramount item in a mining operation is the profit, which is ascertained by subtracting costs from receipts, and costs means everything expended in the complex operations of finding, breaking, extracting, and refining the metal.

Direct comparisons between mines are rendered difficult by the fact that the fiscal years of the companies controlling them end on different dates, although the majority issue statements for the calendar year ending on December 31. Other dates for closing the accounts are due often to the fact that the annual reports start from the birthday of the enterprise. Moreover the promptitude with which annual statements are given to the shareholders varies widely, from a few weeks after the fiscal year terminates to nearly twelve months later. Another obstacle to accurate comparisons arises from the different units of weight and value employed by English and American mining companies. You may wade through a statement of accounts and make your deductions, only to trip over the fact that some of the items are in terms of Mexican currency, while others are in American dollars. Some companies use long tons of 2240 pounds, others the metric ton of 2204.6 pounds, instead of the standard short ton of 2000 pounds. The student of statistics rises up and calls the Institution of Mining and Metallurgy blessed, for has it not done much to remedy this state of chaos!

No one can delve into an accumulation of annual reports issued by mining companies without remarking a coincidence, namely, the enterprises that are best managed are also the ones that give the most complete information to their shareholders. To this rule there is scarcely an exception. Those who are acting as real trustees for the shareholders are quite willing to give a frank and full statement of their stewardship; those who are either incompetent or untrustworthy will adopt the mask of secrecy or indirection. Publicity is the best cure for mismanagement and the most effective spur to right action in mining, as in other affairs.

An Interval.

IN MUSIC an interval has a value of its own; in life a period of idleness can be turned to harmonious account. By reason of the financial disturbance that marked the last quarter of 1907, there has been a curtailment of expenditure in every form of industry, and one of the immediate results has been to throw many professional men out of employment for a while. This period of enforced inactivity can be made as useful in the furtherance of a career as the intense engagement of busy days, if the opportunity be but properly utilized. Do not drift; do not go to your office merely to whittle a stick or whistle a song. If there is nothing to do, play golf and keep yourself physically fit against the time of active service that is coming again soon. Take the opportunity to study, to investigate matters that were put aside during the recent strenuous days. Accept the chance to make the closer acquaintance of other professional men. The knowledge of men is power and a large acquaintance is stimulating. You may find that the fellow in the office just across the hall is an unprospected gold mine of information and interest; you have only had time to nod to him as yet, now is your chance to be human and kind. Run a cross-cut and investigate. Perhaps you belong to a local technical or scientific society, the meetings of which you have as yet had no time to attend; you can go now. Go, by all means, and contribute your share to its usefulness. If necessary, organize a dinner and lubricate good fellowship in the old Anglo-Saxon way. Take out your note-books, put them in order, and systematize the odds and ends of information collected during your professional journeys.

Some of these memoranda are valuable to others besides yourself, arrange them in the form of an article and send them to the technical papers or to engineering societies. Whatever you do, keep awake and cheerful. This period of lessened activity in mining will not last long; prepare yourself for the moment when opportunity will knock at your door and call you forth to new labors. Make the interval count.

Retrospect and Prospect.

THE YEAR just ended has been big with events that throw strong lights and shadows across the future of America. History is no longer made by the birth and death of kings, by changes of dynasty, by battles, by conquests on land or sea. The only history worth anything is the story of human endeavor and the development of the character of a people and the individuals that compose a people. In this respect 1907 has been a great year, rich in lesson and bright with promise.

To many of our readers the exposure of wrong may seem to overshadow the achievement of right. We have seen the violation of the law, the falsification of accounts, and the secret rebates of the Standard Oil Company dragged to light, the legal proceedings initiated by the Government culminating in a $29,000,000 fine; we have seen the grand larceny of E. H. Harriman laid bare, his unscrupulous use of financial power in disregard of all obligations to shareholders, his use of company funds to gamble on a colossal scale; we have seen the post-mortem dissection of the New York traction company flotations and the disclosure of plundering of the most impudent kind; we have seen the collapse of a game of pyramids in which banks were made the sport of a group of plungers; we have seen a sudden panic, an extraordinary collapse of credit, and the spectacle of the rescue of the financial position by a coterie of very rich men, headed by Mr. J. P. Morgan—a rescue that carried with it the sinister suggestion that those who could so easily control the commercial equilibrium for good might likewise control it to their own ends. Finally, here in San Francisco, we have witnessed the exposure of corruption in municipal life, in business, and in politics; we have experienced the effects of an industrial vendetta, marked by brutal deeds and loss of life; we have seen educated men, rich men, men under obligations to support the State, we have seen them on the side of a lawlessness that was in effect anarchy and the year ended in a pitiful exhibition of labor tyranny as applied by the reckless ranter who had the impertinence to be a candidate for the mayoralty of San Francisco.

If the chronicle ended here, it would seem tragic indeed. If these wrongs were heralded without inciting an effort to redress them, the effect would only be to make us callous to the essential badness of such occurrences. But strong compensatory influences are already at work. In San Francisco the forces of corruption are deliquescing, public opinion has crystallized, civic spirit has been aroused; we have elected a mayor who is a scholar and a gentleman; the corrupting corporation and the corrupted labor union are both discredited, honest men need not apologize for living, the fog of a putrid kind of politics is being swept aside by the strong clear air of a brighter day. In national affairs, the aroused resentment of the people—not the dreaming head nor the subjugated feet, but the mass of ordinary plain folk constituting the strength of this continental country—has given strength to the Government's efforts to enforce the law against corporations doing an interstate business and the commanding personality of a President—American to the core, in his impulsive energy, his frankness, and his fearlessness—has given a rallying point to all the forces of reform. To anyone able to view the events of 1907 with any approach to mental detachment it is obvious that we have seen the expression of tendencies inherent in an industrial civilization under an undeveloped form of representative government. We can observe the interplay of rampant individualism, crass selfishness, and the misdirected greed for money, unchecked by law, in fact, using the law in self-protection, undisciplined by government, indeed, corrupting the government—of the municipality, State, and Nation—so as to go unhindered on its debauching way. But these constitute a passing phase. It is the measles and whooping cough of representative government in America. The very ills are creating antidotes more powerful than they, the very exposures of wrong are bringing into vigorous assertiveness the patriotic men able to guide the forces of reconstruction and upbuilding. San Francisco is a type of the United States; the earthquake and the fire, the breath of pestilence and the more pestilent breath of municipal corruption, the selfishness of the few and the ignorance of the many—not one of these, nor all together, has sufficed to stay the forces of reconstruction that out of a terrible desolation of smouldering ruin has caused to spring up, bit by bit, but surely and swiftly, a new city, finer and more safe than the old one; a city that on the stepping stones of her dead self shall rise to be the realization of the unconquerable spirit of man. We believe it, as we believe in the development of the kind of government that is called popular and is meant to be representative. There have been excesses, the excesses of youth—greediness, an unruly spirit, self-assertiveness. It is likely that to correct these tendencies we must have a severe dose of paternalism. The Federal Government must lay a heavy hand on all forms of industrial activity that reach beyond the boundaries of single States, and the law must be enforced to the annoyance even of well-meaning people. Commercial piracy must be checked, predatory finance called to order, the tyranny of corporations and labor unions alike curbed, and in the sequel the Government may have to perform many duties heretofore left to individual or corporate agencies. But beyond this era of paternalism, and during this period of discipline, there is the promise of the development of representative government such as the world has never seen, as much better than the anachronisms of Europe as the monarchies of the old world are better than the rule of a mob. We have full faith in the outcome; we are in the morning of the times, the world is young, and life an epic.

Personal.

C. W. MERRILL is visiting Goldfield.

MARK R. LAMB is now at Mexico City.

BEN. S. REVETT is here for the holidays.

A. C. BEATTY has returned to New York.

FRANK H. PROBERT is here, from Los Angeles.

CHARLES BUTTERS has returned from New York.

W. A. CALDECOTT has returned to Johannesburg.

H. P. GARTHWAITE is on his way back to Salvador.

HENRY HUNT, lately at Bingham, is here for a few days.

FREDERICK F. KETT, lately at Goldfield, is in San Francisco.

NORRIS ENGLISH has arrived in San Francisco from New York.

JOHN W. FINCH is at Denver, and will go to Europe shortly.

H. H. WEBB will leave San Francisco shortly, to proceed to Mexico.

H. H. LAING, lately at Kendall, Mont., is on a visit to San Francisco.

FREDERICK HELLMAN is expected at New York from Johannesburg.

ALEXANDER MCNEIL has left Halifax and will reside at Washington, D. C.

A. P. STANLEY MACQUISTEN, of Salt Lake City, was in San Francisco this week.

REGINALD W. BROCK has been appointed director of the Geological Survey of Canada.

OSCAR H. HERSHEY is now assistant to the editor of the MINING AND SCIENTIFIC PRESS.

R. T. BAYLISS has been elected a vice-president of the Institution of Mining and Metallurgy.

JOHN R. FARRELL, of the Tanganyika Concessions, Ltd., is at the Key Route Inn, Oakland.

ARTHUR W. JENKS has moved from Portland to Seattle, where his office is in the Alaska Building.

F. H. MINARD now has an office in the Trinity Bdg., New York, as well as his former office at Denver.

G. H. BARNHART, lately in British Columbia, is now manager for the Torpedo-Eclipse Co., at Ouray, Colorado.

C. C. BROADWATER, manager of the Little Mono mine, in Siskiyou county, Cal., is spending the holidays at Oakland.

J. M. BOUTWELL is expected at Los Angeles, from Cananea, where he has been making a geological study of the copper deposits.

F. B. CLOSE is now with the Compañia Metalurgica y Refinadora del Pacifico, at Fundicion, Sonora, as general superintendent of mines.

W. H. TREWARTHA-JAMES, of James Brothers, has returned from his recent mission to British Columbia and left for Mexico December 14.

J. E. SPURR, chief geologist for the Guggenheim interests, has arrived at New York after a three months' tour of properties in Missouri, Colorado, California, and Mexico.

JAMES F. BERRY, formerly with the National Metal Co., of Mexico City, has become chief chemist to the Compañia Metalurgica y Refinadora del Pacifico, at Fundicion, Sonora.

JAMES CHAMBERS DICK has been appointed general superintendent of the properties of the Tintic Mining & Development and Yampa Smelting Co. with headquarters at Salt Lake City. CHARLES W. SAXMAN, the general manager, will make his headquarters at New York hereafter.

The Actual Situation of Copper.

Written for the MINING AND SCIENTIFIC PRESS
By JAMES DOUGLAS.

The copper industry, like the rest of the country, has been living in a fool's paradise for the better part of two years, and finds it difficult to accommodate itself again to normal conditions of existence.

When the value of stocks of all kinds rises to fictitious figures, the value of commodities not unreasonably follows suit. Men believed that their paper wealth was real wealth, and spent accordingly, giving too often, however, paper checks in exchange for what they bought. And while this extravagant expenditure prevailed, to meet the demand for the articles wanted and to realize the extravagant prices paid for their commodities, the manufacturer forced production to a degree in excess of his actual legitimate resources and facilities. When the world returned to its sober senses and realized that things were not what they seemed, instead of soberly and reasonably reorganizing its business as well as its household expenses, it suffered a violent reaction of remorse and fear and fell into a panic for which there was no really good reason. This is eminently true of the copper trade. It has been passing through the same phases—first, excessive elation, then morbid depression, and now slow recovery toward reasonableness. No sensible man believed copper to be worth 25 cents or supposed that it would maintain that price; but the price, under abnormal conditions, kept soaring and the large mills kept buying ahead, to the loss of the producers and the mills' material gain, as long as the market continued steadily rising. Unfortunately for the owners of the mills they did not realize that the balloon was leaking gas, and therefore did not stop buying soon enough. Nor did the producers know or appreciate soon enough the extent to which the demand for the manufactured article had begun to decline. This really commenced in April and became pronounced in May; nevertheless, during the whole summer the mines and smelters continued pouring out their boom production, with the result that when the bubble actually burst they found themselves loaded with a lot of copper which it was inconvenient to carry. Some companies closed down their smelting works entirely and devoted their feeble efforts underground to picking up development work, which in the stress of production had fallen woefully behind. Others were only too glad to reduce production below the normal, and give their overworked staff a breathing spell. But others, especially in operating very low-grade mines, have maintained their output and continue to employ their full force.

In Arizona none of the big mines have been closed, and but few of the second and third class. In the Warren district it was considered by the Copper Queen and the Bonanza group good policy to reduce production, and therefore the smelting works of these two groups, which during the first three months of the year sent into the market 41,000,000 lb. of copper bullion, during the last three months shipped only 26,500,000 lb. The Clifton district, working on ore that does not average over 2½% copper, and contains no gold and silver, and where therefore administration expenses form a large proportion of the cost, have not reduced their production or abated their activity.

The Old Dominion furnaces have turned out during the past year approximately the same amount of copper as in the previous year, and there is no apprehension of a serious falling off during 1908. But forecasts are doubtful, as so many unforeseen contingencies arise, disturbing the most cautious calculations.

In the southwest the most regrettable incident of the recent depression has been the closing of the Humboldt smelter, on which the many small mines around Prescott had been depending for the treatment of their ore. It is to be hoped that the embarrassment of the company will be soon relieved. Custom works have run a very serious risk, and inevitably do so when the market has been as unstable as of late. They must pay small customers cash for their ores, and yet cannot realize the copper for approximately the three months during which the bullion is being transported to the East and refined electrolytically. Upon a rising market they gain and are liable then to reduce their smelting charges with a view to increased business, or put their gains into enlarged works for increased capacity. When, therefore, they come to lose heavily on a falling market, especially when there is such complete paralysis of trade as happened during the past summer, they are liable to become seriously embarrassed.

Were it not for the accumulation of stocks and the extraordinary increase in the cost of mining and smelting which have resulted from the so-called good times there need be no distress in the trade, for the present price is higher than that ruling in 1904, when the average for electrolytic copper was 12.823 cents. But during the prevalence of the high price of copper, every item that entered into the cost of the metal, increased to such a figure that it may safely be assumed that the cost of mining and smelting copper ore rose on the average three cents per pound over that prevailing before the period of exaltation. Wages, timber, fuel, and mining supplies increased in price. The railroads were unable promptly to handle such freight as they accepted, and the excessive local demand for Western fuel, or the convenient excuse of car shortage, obliged the smelters of the Southwest to import Eastern coke at very heavy cost. Had it been transported promptly and received when a high price was realized for the copper, its receipt would have been acceptable; but arriving still at this late date, it aggravates the embarrassment. Nevertheless, the values of what the companies have to consume are adjusting themselves to the lower price of what they have to sell, and when the process of re-adjustment is completed, which should not occupy a long time, and the trade has recovered its balance of mind, so acutely disturbed by 26 cent copper, it will be found that no one has been seriously hurt, except those who speculated recklessly in stocks or in worthless mines.

THE Standard group of mines at Bodie, California, has produced in 25 years $14,500,000. This output has been mined from a system of more than 100 veins, distributed through a zone about 2000 ft. in width; they varied in thickness from 0.5 in. of 'specimen rock' to 30 ft. of clay and quartz. The Bodie district occupies an island of Tertiary hornblende-andesite, surrounded by a complex of igneous rocks and breccias. The veins represent at least three distinct periods of formation. The oldest series, the Fortuna, is cut up into short segments, being dislocated by each of the succeeding ones. Its ore is characterized by hard, flinty, at times bluish, quartz. It has the largest percentage of silver of any of the system. The veins of the Incline series showed a relatively small proportion of coarse gold, and stood low in silver percentage. They have been classed as gash-veins, and their marked characteristic is the fading-out of value at about the 500-ft. horizon. The Burgess series has small, nearly vertical veins, with a slightly banded structure. The value was chiefly in exceedingly coarse gold. Their ore-shoots were included between east and west planes about 600 ft. apart, as against 3000 ft. for the Incline and 1000 ft. for the Fortuna series.

Psychology of Mining Booms.

Written for the MINING AND SCIENTIFIC PRESS
By J. H. CURLE.

My personal knowledge of mining goes back to the year 1891, but for the purpose of this argument it may be taken as beginning with the Transvaal boom of 1895. After that period of excessive mining speculation, there occurred the outbursts of Cripple Creek in 1895; New Zealand in 1896; Klondyke in 1898; British Columbia in 1898; Rhodesia in 1899; West Australia in 1899; West Africa in 1902; Egypt in 1904; Buenos Ayres in 1905; Siberia in 1906; Nevada in 1906; and Cobalt in 1906. There have been, during this period, many outbursts on a smaller scale, similar in character to these bigger occurrences, but these well known booms are enough for illustration.

These thirteen mining booms, following upon discoveries of more or less value, took without exception one definite course. After an initial period of scepticism results from one or two mines in the new district led to great financial excitement, and to wide advertisement. Outside promoters entered the field, and capital poured in; for one good mine twenty worthless ventures were floated; the shares, good and bad, rose to absurd prices; and the *facts* became obscured in an atmosphere of lying and brainless optimism. Then, sooner or later, came the crash. This was always thorough, and in each case dragged down thousands of more or less foolish and deluded people.

There is a law in these things. I have made the statement, not hard to verify, that these thirteen mining booms took a definite course. I shall go further and affirm that *all* mining booms take this course; for although there may be minor differences in their inception, all are based on slender material, in all are the same forces at work, and all result in eventual disaster. This law, which defines so surely the course of a boom, has many other manifestations. We may hope that a scientific generalization of its actions may one day be added to the world's knowledge. For our specific application, the dynamic forces at work may crudely be set forth as follows:

On the one side, making for moderation, we have the experience of very many booms, with their invariable over-valuation and certain disaster. We have also the sure knowledge that ore deposits are treacherous things on which to base hopes. On the other side we have the incurable fatuousness of human nature. This of itself is a force of the first magnitude, and it is supported by the company promoters, by the weight of capital, and by a large section of the press.

At the beginning of a mining boom these rival forces take the field. But how unequal they are! The struggle is a matter of form only. The *law* is at work, and there can be but one end. But what an immoral law, Nature! Truth, moderation, fair dealing between man and man, are doomed with certainty to go to the wall, for perhaps a period of years, while lies and foolish imaginings flourish.

Then for the mining boom in the abstract. Let us now take note how these things affect themselves. As miners, pure and simple, we don't want booms, for their aftermath brings disillusionment to the public, and consequent discredit to the mining profession. But are we, I wonder, prepared to say that this discredit is not merited, or do we, or do we not, as a profession, connive at the evils which flourish previous to, and during, a boom?

It is, of course, evident that the mining profession as a whole does not connive at these things, and stands for what is decent and legitimate. But the influence of the profession as a whole is a vague sort of force. It does not compare with the influence of those units in the profession who appear on the stage during the course of any given boom. It speaks with insufficient weight and prestige, and often, in order to placate the capitalists, speaks under its breath. About twice a year, as a consequence, the company promoter and his friends take the floor in a struggle for supremacy, and as often as this happens the mining profession gets struck across the head heavily with a club for trying in too feeble a way to speak up for what it knows to be the truth. If we were efficient there would be no booms, for we should control public opinion, and mines would be valued rationally. But seeing that the opposite state of affairs obtains, that is, continuous over-valuation of mines, verging frequently into booms, it is evident that there must be much inefficiency in our ranks.

Let us analyze this. A few technical men are habitually dishonest; a larger number, afraid for their billets, look on while their directors manipulate things. A still greater number bear no influence at all, for good or ill. Their views as to the values of mines—about which booms wax and wane—are as indefinite as their characters. These are the kind of men that bring mining into disrepute and make booms possible. Their influence more than outweighs that of the rank and file of straightforward competent men who direct the mining operations of the world. The able men of the period, made wise by experience, view the recurring booms rather cynically than otherwise. They gamble, probably, but knowing as by instinct which are the good mines, buy into these and take out good profits before the boom reaches its height. They see one after another of their less gifted fellows making fools of themselves; one in writing an unduly optimistic report; another in allowing himself to be made the whipping boy for his director's trickery; and a third in plunging into scrip just as the crash comes. These astute individuals look on. They understand the forces at work, with their inevitable results, and play their cards accordingly.

In the presence of a mining boom we are as helpless as the medical profession in presence of an epidemic. The one is as surely a disease as the other, and should be stamped out at its inception. Neither, indeed, should be allowed to germinate. This line of reasoning is, I feel sure, correct. I know there are those who argue that booms have their uses; that they encourage the flow of capital into mining, and that by allowing the able to score at the expense of the fools they carry out nature's laws of the survival of the fittest. Well, there is a good deal in this. The love of gambling cannot be eradicated by official decree of the mining profession, and if people don't gamble in mines they will in other things. I gamble myself, now and then, but I am still prepared to argue that the profession is better without these periods of excitement, founded as they are on lying and unwarranted optimism, and I believe that the final weight of opinion will endorse this view. If we could present a united front of strong able personalties against the powers of darkness—represented in this case by human fatuousness, backed by the promoter and his myrmidons—there would be no more booms, for they could not generate in such an atmosphere. Taking things as they are, we realize that the profession carries its due share of undesirables, that we cannot get rid of them, and therefore that these evils will continue to exist as in the past. The boom will come, with its attendant evils, and the official voice of the profession, raised in warning, will be as ever, calmly ignored by the world. But it is worth while to protest.

What there is to do rests with the individual. Let him, in the crisis, be guided by facts, and facts only. He must not lose his head. With slight reflection he will realize that the boom will be followed by certain disaster, and that the good name of mining will suffer. He must do what he can do to preserve this good name. No flabby reports, meaning anything or nothing, must be written; no elastic estimates of ore in reserve must be made; there must be no cringing to boards of directors over matters of right and wrong; and nothing must be conceded where a delicate sense of honor calls for the truth.

RAILROAD RATES IN MEXICO.—The Federal Railroad Commission has recommended to the Department of Communications increases of 10, 20, and 30% on the three respective classes of ores as established and asked for by the railroads. Ores are to be divided into three classes, as follows: Up to P25 value per ton the increase in freight rate will be 10%; ores from P20 to P50 per ton in value, 20% increase; and ores exceeding P50 per ton in value, 30% increase. It is entirely probable that the new rates as recommended by the Commission will be adopted by the Government. However, owing to the crisis through which the mining industry in the country is passing, in the progress of which a number of mines are being closed down, owing to the depreciation in the price of metals, it has been deemed inexpedient to put the new increased rates into effect at once, and this point is now under consideration. The mining industry gets off better than it had reason to expect, as the increases to be recommended are far lower, on the whole, than the railroads were demanding. As an example of what mining is to the railroads the last annual report of the Mexican Central shows that out of a total of 3,545,538 tons of freight handled up to June 30, 1907, 1,931,840 tons consisted of ores, metals, fuel, material, machinery, etc., carried to or from mining camps. The report of the National Lines showed that 48.61% of their freight traffic was due to the operation of mines and smelters.

COPPER ranks third among the products of California's mines. The order of value in California's principal mineral products is, gold, petroleum, copper, clays and their products, cement rubble, and quicksilver.

Production of Precious Metals.

By the courtesy of Mr. Frank A. Leach, Director of the Mint, we are enabled to publish his preliminary estimate of the production of the precious metals in the United States in 1907, and a comparison with 1906. These figures are based on the exact receipts of the various mints and assay-offices for 11 months, and refinery and smelter statements for from 9 to 11 months.

The table herewith shows a reduction in the gold yield of the United States for 1907, the estimated total production this year being $89,617,007 as against $94,373,800 for 1906.

There is but little difference in the total production of silver, the apparent yield in 1907 being 56,925,911 fine ounces as against 56,517,900 for the year 1906.

The gold recovered from the copper ores of California in 1907 will amount to about $2,188,000, an increase of about $898,000 over last year's product from that source. The yield of gold from the other sources of mining show a falling off of about $2,340,000, making the net loss, in round numbers, $1,500,000 in the gold yield of California.

The shrinkage in Colorado is about the same as for the previous year.

The large falling off in South Dakota is due to labor disturbances and the fire in the big Homestake mine.

For the first half of the year the output from the mines of Utah, Idaho, Montana, and Arizona indicated increased yields for these States, but the sudden drop in the selling price of those metals which gave gold as a by-product caused a great curtailment in the yields of these mines in the last part of the year by reason of the closing down of many of the big producing mines.

The world's gold product for 1907 is estimated at $103,000,000, or a gain of about $4,500,000 over the preceding year. Africa will give a gain of about $17,000,000, which, with gains of $1,000,000 elsewhere, gives a total gain of $18,000,000. On the other hand the losses will be about as follows:

United States	$4,700,000
Australasia	5,000,000
Other regions	4,100,000
Making a total of	$13,800,000

thus reducing the gain to $4,500,000, and it is likely that the final figures may reduce this excess somewhat.

The commercial value of fine silver in 1906 averaged about 68c. per ounce.
The commercial value of fine silver in 1907 averages about 66c per ounce.
The production of fine silver in 1906 amounted to 56,517,900 ounces.

The Great Gold Mines.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The most productive gold mine in the world in 1906 was the Esperanza (at El Oro, Mexico) which yielded $7,708,883; it was also the most profitable gold mine, for the profit won in that year amounted to $4,644,279. The most productive gold mine in the world in 1907 was the Goldfield Consolidated (at Goldfield, Nevada) from which $6,296,476 was extracted, but it was far from being the most profitable mine during that year. The most profitable gold mine in 1907 was the Robinson (at Johannesburg, in the Transvaal) the earnings being estimated at $4,300,000. The greatest gold mine in the world today, having regard to the present rate of production, the profit earned, and the magnitude of its ore reserves, is the Robinson. These statements summarize a careful review of the performances of great gold mines in widely scattered regions.

In preparing a list of the great gold mines, it was intended to mention all those that yield $1,000,000 per annum, but this would have furnished a statement lacking in variety, for of the 80 mines fulfilling such a condition, no less than 53 are in the Transvaal. This fact emphasizes the dominant position of South Africa among the regions producing gold. But it is scarcely more than was to have been expected, for Africa produces 30% of the total production of the world, and the single district of the Rand yields more than either the United States or Australia, the two countries ranking next in production. Out of the 53 South African mines yielding over $1,000,000 per annum, I quote statistics for the 19 most productive. Each of these 19 mines now contributes 10,000 ounces of gold per month, that is, abont $2,500,000 per annum. All the ore is crushed in stamp-mills, ranging in size from 100 to 360 heads. In many cases tube-mills are used for re-grinding, with the further result that the rate of crushing is increased. The average duty is 5.67 tons, with a maximum of 8.8 tons per stamp per day. From the 66 productive mines on the Rand in August, 1907, for example, the total profit in that one month aggregated $4,400,000. The profit yielded by 63 of these amounted to $4,258,441, which was the result of treating 1,317,799 tons of ore. The average yield was $8, the profit was slightly over $3, and the working cost slightly under $5 per ton. One-half the companies were working ore yielding a profit of less than $2.50 per ton. Of the 32 leading companies, 15 earned a profit of between $1.80 and $2.50 per ton, 8 won between $1.25 and $1.80 per ton, and 9 got under $1.25 per ton. In the next month (September) the 19 leading mines varied in their earning capacity from a profit of $2.22 per ton to a maximum of $8.79 per ton.

Among the mines of the Rand, the Robinson and the Simmer & Jack are in a class by themselves. Each of these two mines is yielding over $500,000 per month and the two properties contribute about $12,500,000 per annum or 3% of the entire output of the world's production. The Robinson is now earning at the rate of $4,500,000 profit per annum and the Simmer & Jack a little over $2,500,000 per annum. In October the Robinson made a profit of $376,390. During the year ending June 30, 1907, the 320 stamps of the Simmer & Jack crushed 717,524 tons of ore, yielding $5,595,537, of which $2,363,308 was profit. The average duty was 6¼ tons per stamp per day. The dividends amounted to £300,000. The yield per ton was $7.80; the cost, $4.51; and the profit, $3.29 per ton. Of the ore hoisted 16.83% was sorted out. It is calculated that the ore already developed amounts to 1,694,000 tons, that is, a supply sufficient for a little more than two years, and the average content of these reserves is 7.7 dwt. per ton. The undeveloped reserves, that is, the tonnage of ore estimated to exist within the boundaries of the property, amount to 11,000,000 tons.

In the year ending December 31, 1906, the Robinson yielded 435,474 tons, of which 74,103 tons was sorted out. The ore sorted out represented 17% and it assayed 1.005 dwt. per ton. The assay value of the ore milled was 14.26 dwt. and the actual yield 13.288 dwt., or 93% of the contents. The 210 stamps ran for 336 days, the duty averaging 5.13 tons per head. Three tube-mills were added to the plant. On December 31, 1906, this company was employing 462 white men, 146 Indian coolies, and 2461 Kaffirs. While the ore developed in this mine at the end of 1906 was estimated at 2,180,700 tons of an average assay value of 14.22 dwt., the ground covered by the property is calculated to contain sufficient ore to last 12 years, that is, it contains between 4,500,000 and 5,000,000 tons of ore equal in richness to that now being extracted.

An example of the eventual exhanstion even of the best of mines is afforded by the Bonanza, which up to the end of 1906 had yielded $13,257,528. Being a property of small area it serves to emphasize the fact that the individual mines of the Rand have no apex rights and therefore cannot follow the dip of the lode under adjacent ground. The possibilities of deeper exploration are cut off sharply and there is no hope of postponing the

*Seven months only.

The records given in this table are for the year ending December 31, 1906. Fine gold is taken at $20.67 per oz. and the pound sterling as equivalent to $4.85. In October, 1907, the Robinson brought costs down to 14s. 9d. or $3.56 per ton, and made a profit of £77,606 or $376,389, on an output of 25,298 oz. fine gold. In August the Robinson transferred £50,000 from the gold reserve to current output, making a maximum month's production of $735,760, of which $582,175 was profit.

end of productiveness as in most mines operated under the American law. Another example is that of the Jumpers Gold Mining Co., whose mine is to be exhausted by December, 1908, by which time the 112,000 tons in reserve on July 31, 1907, will have been extracted. The lode so profitably worked by the Jumpers will be followed downward by the Jumpers Deep, into whose territory it dips.

The regularity of production characteristic of the South African mines is to be credited not wholly to the comparative uniformity of the ore and the ability of the manager to overcome variations in the gold content of the material coming from different stopes; it is due, in large part, to the practice of holding a reserve of bullion, which is used to sweeten the output when, by reason of any untoward event, it fluctuates below the normal. This reserve ranges from 1000 to 5000 oz., with even larger amounts in the case of the biggest mines; thus, in September the Robinson carried a reserve of 16,109 oz.; the Robinson Central Deep, 10,996 oz.; and the Crown Deep, 10,521 ounces.

After the Rand the most productive district is Kalgoorlie (in Western Australia), which in 1906 yielded $20,430,000 and in 1907 about $18,000,000. Out of the $9,661,500 dividends paid by West Australian gold mines in 1906, no less than $7,651,050 came from ten mines at Kalgoorlie. These are contiguous to each other in a small tract of schistose diorite so thickly traversed by rich orebodies that it is known as the Golden Mile. Kalgoorlie was discovered in 1893 and reached its most productive stage in 1903, when this district (called officially East Coolgardie) yielded gold worth $21,970,101, out of the $40,427,558 credited to the whole of Western Australia. Since then closer attention to economy and improvements in the metallurgical treatment have lessened the working costs, so as largely to balance the decline in the tenor of the ore. Although lower grade in depth, the ore has proved persistent in several of the big mines. The deepest stopes are in the Great Boulder at 2050 ft. At the end of 1906 this mine had reserves of ore amounting to 548,490 tons, estimated to contain 501,376 oz. of gold, worth $10,000,000. The Oroya-Brownhill and Golden Horseshoe each produced close to $3,000,000 in 1906. The Golden Horseshoe had four years reserves assured, the 993,000 tons blocked out being estimated to contain $14,000,000 in gold. The deepest workings were at 1600 ft. The Oroya-Brownhill, up to the end of 1906, had produced $20,775,000 from the two mines now consolidated under the compound name; the present company having extracted $13,390,850. The maximum depth is 1500 ft. In 1906 this mine yielded £630,318 and made a gross profit of £501,932, from which £46,811 was deducted on account of depreciation and £26,560 for shaft-sinking and development. The cash in hand, after paying dividends amounting to 80% on the capital, was £300,000. In 1903 the working costs were $6.78 per ton; in 1904 they were reduced to $6.48; in 1905, $6.04; and in 1906 they were brought down to $5.28 per ton — so that ore carrying 5 or 6 dwt. can be worked at a profit. The crushing capacity of the mill has been increased from 5½ tons per stamp in 1904 to a duty of 7½ tons in 1906. The Great Fingall Consolidated is an example of the proverbial tenacity of English shareholders, for the first mine upon which the company was organized having proved a failure, the directors acquired the Day Dawn mine, near Cue, and from it the company has paid $7,375,000 in dividends. Now that it shows signs of exhaustion, the directors are looking for a new property and they have been considering the acquisition of the old Burra Burra copper mine in South Australia. Similarly, the Ivanhoe company has sent engineers to Mexico and the negotiations for the purchase of a property there only broke down by reason of the high price asked. The most amusing instance of this kind was that of a company that was formed to work a mine in New Zealand and then shifted the scene of its operations to a mine in India, and when this became impoverished it acquired property in Madagascar. The mines die, but the company goes on. This method has the merit of conserving experience.

At one time, in 1899, Kalgoorlie boasted the most productive gold mine in the world, for in May of that year the Lake View Consols yielded 33,160 oz., worth about $660,000, and in the 12 months it gave 199,230 oz., or $3,897,479. Shortly afterward it became the centre of a disgraceful fiasco, followed by bear raids and exposures affecting neighboring mines, until Kalgoorlie became a name of ill repute. Since then systematic management and the best engineering skill have done much to restore the local industry to a healthy condition. As with men, so with mines, good behavior is apt to come after the vigor of youth is past.

The gold-mining district ranking third is Cripple Creek, in Colorado, which in 1906 produced $14,250,000 and in 1907 about $13,000,000. At the present time Cripple Creek can claim no mine of the first magnitude and a large part of the production comes from small properties operated under lease. But this district, famous for its telluride ores, its labor troubles, and its stock boom can boast at least two mines that at one time commanded general attention. These two are the Portland and Independence, which are contiguous and on the same system of veins, traversing andesite breccia where it is crossed by numerous dikes of phonolite. The Independence was discovered by W. S. Stratton on July 4, 1891. Since its discovery in 1891 it has produced fully $17,000,000. To the English company to which it was transferred in April, 1899, it has yielded a profit of over $5,250,000, and to the lessees during the past three years it has given a further profit, not included in the above total. *From which $315,788 was charged off to mine development and depreciation of plant.
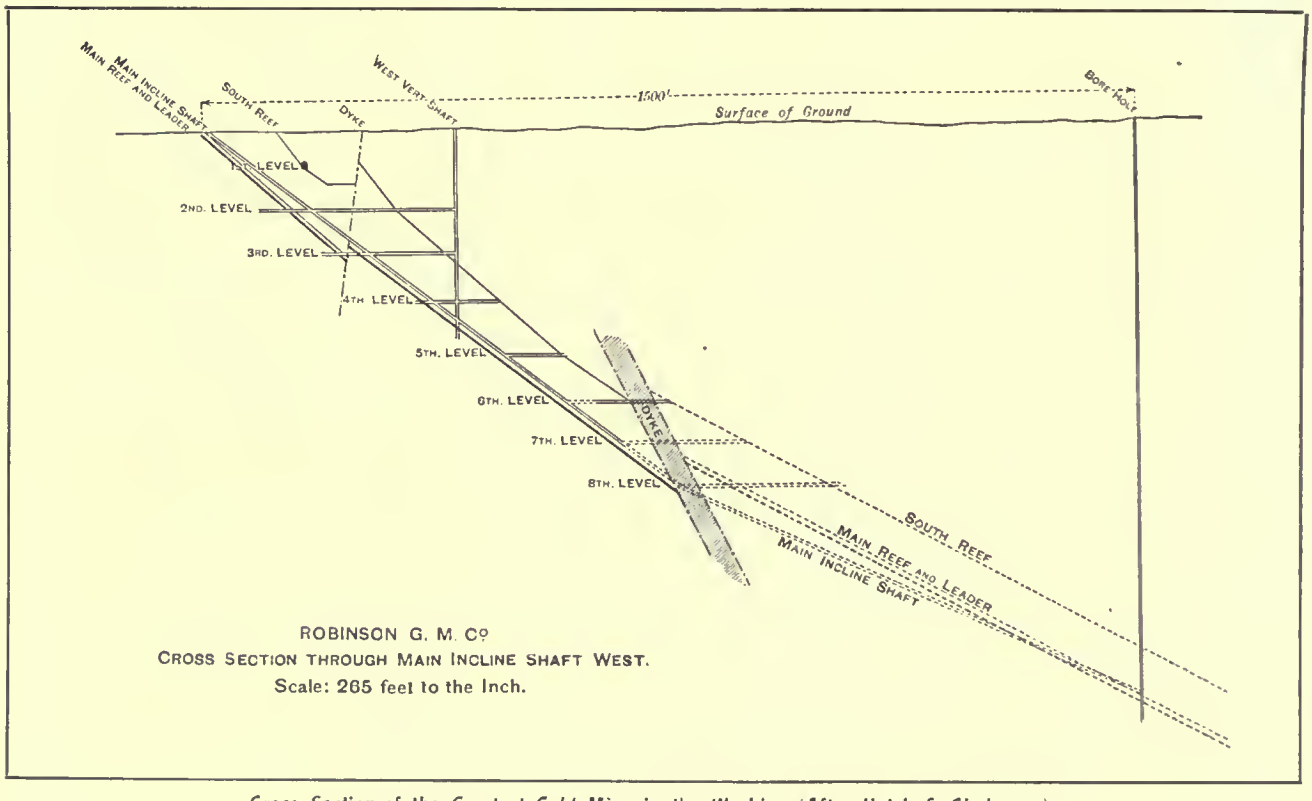
The outputs for this list are for the calendar year 1906, except in the cases of the Kalgurli mine, which is for the 12 months ending on June 30, 1907, and the Mt. Morgan, whose fiscal year terminated on May 31, 1907.

dends declared by the Stratton's Independence company aggregate $5,028,568. To Stratton himself the mine yielded a profit of $2,500,000 before he sold it. For the year ending June 30, 1906, the output was 75,260 tons, yielding $1,245,121, out of which the company got a profit of $340,965. In the year ending June 30, 1900, this mine also has been the scene of queer doings; early in its development it became controlled by a group of illiterate men and the vagaries of one of the most ignorant of them have involved the mine in a series of lawsuits and recriminations. Despite bad management, it has proved a great bonanza. To the end of 1906 the

Witwatersrand Deep Mine. A Typical View of the Rand.

this mine yielded gold to the value of $3,500,000, of which $2,000,000 was profit. After 16 years of productiveness, after having been the basis of an extraordinary flotation, the subject of a fiasco that caused the loss of money to many, and the excuse for a big lawsuit that Portland had yielded $25,034,411 from 775,110 tons of ore, yielding $7,147,080 in dividends. The biggest production was in 1903, when the mine yielded $2,608,993 from 90,244 tons. During 1906 the output was 92,265 tons, worth $1,817,256, from which a profit of $512,106



Cross-Section of the Greatest Gold Mine in the World. (After Hatch & Chalmers.)

was intended to drag an aniseed bag across the trail of financial misdoing, this splendid mine is now worked out; there remains a big dump of low-grade stuff, but the Independence has had its day—a day checkered by some romance and a good deal of spoofery. Next to it is the Portland, which was discovered in the same year. was made. This mine has seen its best days, although not without some resources.

After Cripple Creek comes the Kolar district, in the State of Mysore, India. A group of nine mines yields $11,000,000 per annum. In 1905 the maximum output was attained, namely, 627,700 ounces, worth $11,639,928.

The ground on which the mines are situated is part of a concession granted by the Mysore government in 1881. At the present time the Mysore is the most productive of this group, yielding 17,000 oz. per month. In 1906 this mine produced 185,900 tons of ore, yielding 205,918 oz., worth $3,925,652, giving a profit of $2,231,068. The reserves are stated at 747,000 tons, or a supply sufficient for four years. The deepest workings are at 3500 ft. on the pitch of the ore-shoot, which is in schist. The system of working this mine is remarkable from the fact that the working shafts have been sunk on the pitch of the shoot, not on the dip of the vein. The pitch is about 30° from the horizontal. The bottom workings look healthy. The dividends to the end of 1906 amounted to $23,402,300 on an original capital of $1,479,250 or £305,000. In 1906 the Champion Reef was nearly the equal of the Mysore, but it has declined notably since then, so that at present it yields only 10,000 oz. per month. In the year ending September 30, 1906, the Champion Reef mine produced 203,174 tons, yielding 177,641 oz., worth $3,291,724. From this a profit of $1,685,903 was made. Of the other important mines, the Ooregum and the Nundydroog yield from 5000 to 6000 oz. monthly. On the whole, the Kolar goldfield has repeatedly surpassed reasonable expectations and the recent developments in depth encourage the expectation of many years of steady, though slowly declining, productiveness.

The district ranking fifth is El Oro, in the State of Mexico, and about 90 miles northwest from the city of Mexico. Here there are three big mines and one of the very first magnitude. The Esperanza and El Oro are on the same lode, the San Rafael vein, while the Dos Estrellas is on a parallel system of veins traversing the same ridge of schist, which is covered with a cap (600 ft. thick) of andesite. The Esperanza was worked by an American company before it was transferred to a London corporation in 1903. For a while it proved a disappointment, but the discovery of a wonderful bonanza, at the end of 1904, prepared the way for a tremendous output. The discovery of an entirely new rich vein was made by diamond-drilling. At one time the Esperanza was much the most productive gold mine in the world. During the month of November, 1905, the output was 10,164 tons, yielding $748,535, or even better than the Lake View Consols when at the top notch. The profit for that month was $473,946. The Esperanza mine continued in bonanza during 1906, the output for the calendar year being 207,183 metric tons or 228,419 short tons, having a gross value of $7,708,883, from which a profit of $4,644,279 was earned. In 1905 the output was 204,299 tons, containing $5,101,135, yielding a profit of $2,923,212. Up to the end of 1906 this mine has yielded (to the various companies that have owned it) no less than 38,347,918 pesos (about $20,000,000) from an output of 871,992 metric tons. Of the output for 1906, 144,286 metric tons were milled and 62,897 tons were shipped to the smelters. The cash on hand and unrealized ore were estimated at $2,221,817. The reserves of ore in the mine were calculated at 141,663 metric tons, expected to yield a profit of $1,481,307. It is obvious that the record for 1907 will fall far short of the two past years and that this mine must lose its premier position. At the present time the Esperanza is producing at the rate of $2,750,000 per annum, of which $1,250,000 is profit, so it is still one of the big fellows, although without any assurance of a maintenance of this rate of production for even a year longer. The workings are only 800 ft. deep, while the adjacent mine of El Oro (to which the district owes its name) is 1100 ft. deep. During the 3½ years of the present company's existence, the Esperanza has produced 541,421 metric tons, yielding $14,407,958, of which $7,631,737 has been profit.

The El Oro was worked by the Mexicans before it was purchased by J. B. Haggin, by whom it was sold to the present English company in 1898. During the year ending June 30, 1907, this mine produced 260,304 tons, yielding $2,243,468, of which $1,902,185 was gold and the remainder silver. The total working costs averaged $5.01 per ton, and the percentage recovered in the mill was 86.63. It is estimated that the reserves of ore amount to 532,523 tons, containing an average of $8.44 per ton in gold, besides 3 oz. silver. Dividends for the year totaled £126,000.

The Dos Estrellas mine is controlled by J. G. Fournier and his friends, who operate under a Mexican organization. The production for the year ending December 31, 1906, was $2,230,360 in gold and $743,797 in silver, making a total of $2,974,157, with a net profit of $970,800. In the report these amounts are given in Mexican currency and I have divided them by two to convert them to American units. The reserves of ore are stated to be 4,000,000 tons.

Of the three mines above reviewed, the El Oro is exhibiting a surprising improvement on the lowest level, suggesting that a sulphide zone of profitable exploitation may succeed (after an interval of almost barren ground) the upper zone of rich oxidized ore, and the Dos Estrellas, being now equipped with a new cyanide plant, is expected to maintain a large production for many years. Another mine—the Mexico—which adjoins the Esperanza, and is on the same lode-channel as the Esperanza and El Oro mines, promises to win a position in the first rank of mining enterprises, but as milling operations only started in 1907, there is no large output to record yet.

(TO BE CONTINUED.)

ELECTRIC SMELTING OF COPPER. — The use of electrothermal processes for smelting copper ores has been proposed in recent years, and in a few cases experimentally tested. The whole question depends on the recognition and appreciation of a few fundamental facts. By far the great bulk of all copper ores are sulphide ores, and in many cases the sulphur and iron present are sufficient heat-producers to allow of the smelting of the ore simply by the heat of their oxidation, if the operation is skillfully conducted. Such is the basic principle of pyritic smelting, and whenever it can be applied it is very economical to do so, and electric processes have no chance of an application. Other ores of copper contain so small an amount of the metal that the result of the smelting down of the whole to a fluid mass by any method of fusion would not repay the cost of the operation. Some such ores can be treated by aqueous and other methods not involving fusion, with a margin of profit to pay for the operation. The only field for electrothermic processes appears to be in the smelting down of ores carrying too little sulphur to be pyritically smelted, and which require, as usually treated, the use of carbonaceous fuel to assist the fusion. Wherever such fuel is expensive and electric power may be obtained at a low price, an electrothermic process might be theoretically possible and profitable. Such conditions may easily occur in the vicinity of copper mines. Situated frequently among the mountains, remote from railways and cheap fuel, they frequently are near large water-powers that would furnish cheap electric power. Some may be even so situated that concentration of a lean sulphide ore to matte by use of fuel or by mechanical concentration would be unprofitable, and yet a concentration or simple melting to matte by electrically-generated heat be profitable. There are no electrothermal processes yet in commercial operation on copper ores, yet they have been tested experimentally with promising results.—J. W. Richards.

Method of Collecting Statistics.

By WALDEMAR LINDGREN.

*The statistics of gold and silver collected from the mines by the Geological Survey are obtained from the following four items: (1) Gold and silver in placer bullion produced during calendar year. (2) Gold and silver in mill bullion produced in mill of company during calendar year. (3) Gold and silver in base bullion, matte, etc. (by assay-value), produced in smelter of company during calendar year. (4) Gold and silver in crude ore and concentrates (by assay-value) shipped to custom works in calendar year.

The first item needs no explanation. The second and third items cover the cases of mining companies which have their own reduction works; they report the gold and silver bullion produced during the year, or the gold and silver contained in their metallurgical products sold to refineries, as there are very few smelting works owned by mining companies which also refine their bullion.

The greatest difficulties are found in the fourth item, comprising ores and concentrates shipped to custom works—generally smelters, more rarely mills—as a considerable interval of time, often thirty days or more, elapses before the ore reaches the works and often much more before it is reduced and refined. It is mixed with other ores and loses its identity, and the assay-value is the only guide the miner has to the quantity of metal produced. In these cases the miner is requested by the Geological Survey to give the tonnage and assay-value of ores and concentrates shipped up to the end of the year.

It should be emphasized that the table of mine production does not give the contents of the ore mined during the year. Only the ore that is treated or sold is recorded. Neither does this report give the assay-value of the total tonnage; for if this were the case the heavy losses in concentration would be disregarded, and the results would be very much larger and wholly misleading. As far as possible the report aims to give the metals recovered from the tonnage sold or treated during the year. In items 2 and 3 this is substantially correct, except for the very small refining losses. In item 4 the amount given is theoretically larger than the actual recovery of refined metals by the combined smelting and refining losses. Practically, however, this is counterbalanced by several factors: (1) Small quantities of gold and silver are recovered from many ores, but not paid for by the smelting companies or recorded in the settlements. As a rule, payments are not made on less than 2 ounces of silver or 0.05 ounces of gold per ton. (2) Settlements are made on the basis of 95 per cent of New York price for silver and of $19 to $20 per ounce of gold. Small producers, who often report in terms of dollars alone, are very likely to give a correspondingly smaller value than the ore actually contains. The same class of producers occasionally also misunderstand the questions and report net instead of gross proceeds. The gold is sometimes also given in value only, which is then always smaller than the actual value of the metal in the ore by from $0.67 to $1.67 per ounce. (3) There is always a certain small percentage of the product which can not be obtained from the miners. This includes the output of scattered individual placer workers, often aliens. There are further cases where owners of small mines decline to answer or where the property is not continuously operated and the owner cannot be found. There is, lastly, the ore abstracted by ore thieves, which takes away a notable fraction of the production of mines containing rich ore. Through assay offices this gold finds its way to the mints.

*Abstracted from 'Mineral Resources of the United States.' Advance chapter.

CALIFORNIA.

By CHARLES G. YALE.
Statistician to the United States Geological Survey.

*California produced in 1906, according to returns from the mines, 906,182.36 fine ounces of gold, valued at $18,732,452, a decrease from 1905 of $166,093. In silver the production was 1,220,641 fine ounces, equivalent to $817,830, an increase for the year of $167,821. The most marked increase was in the copper, the gain in which for 1906 was over 12,000,000 lb. in quantity and $2,939,388 in value as compared with the output of 1905. The lead shows a slight falling off, and zinc appears for the first time in the statistical tables of California.

The total tonnage of ore for the year is 2,556,053, which is 140,550 tons less than in the previous year, although there was an increase of 8914 tons in concentrates. Of silicious ores, 2,235,912 tons were treated, the average value being $8.36. Of copper ores 91,575 tons,

[We venture to add a postscript to Mr. Yale's article. The annual gold yield of the State continues to be about $18,500,000, with some show of an increase due entirely to the operation of the gold dredges. The figures given in the official statistics for the year 1906, are not likely to be materially changed for the past year, though some increase in the gold output may be looked for owing to greater yield of the dredges near Marysville and Folsom, as well as some increase from those at Oroville. The largest dredge in the State is working successfully near Folsom and is handling an immense quantity of profitable gravel. The several large machines of the Yuba Consolidated Co. above Marysville are doing wonderfully well, and the company is now producing more gold yearly than any other in the State, either quartz or gravel. These enlarged operations must necessarily exercise a marked influence on the gold output of California. Indeed, otherwise there would be a falling off in yield. The Utica, Lightner, Angels, and other productive mines in Calaveras county were closed several months during 1907 owing to labor troubles, and there is virtually over $500,000 loss in that locality. Some other quartz mines have not been so productive during the year as usual. At the same time the three largest quartz gold producers, the Kennedy of Amador county and the North Star and Empire mines of Nevada county, have been doing better than usual. Less gold will be shown from Shasta county than in 1906, as in the latter part of 1907 the copper smelting operations were restricted by reason of the low price of that metal. Less fluxing ores, carrying gold and silver, were therefore used.

No increase is to be looked for from the drift mines or from the hydraulic and placer operations. As stated, therefore, if more gold is found to have been produced than in the previous year, it is due to dredging operations. The silver output will probably be found to be somewhat less than in 1906 owing to conditions in Shasta county, which is usually the largest silver producer. Next to gold, oil is the most important of California mineral products. It is expected that when the final figures of 1907 are complete, it will be found that the oil increased in amount some six or seven million barrels. In the latter part of the year the price was almost double that of the earlier months, so the oil men have doubtless done well in 1907. As to copper, a lessened output is expected naturally from the fact that so many important mines closed their plants during the last two months of the year.—Editor.]

*Abstract 'Mineral Resources of the United States,' calendar year 1906.

PRODUCTION OF GOLD, SILVER, AND ASSOCIATED METALS IN CALIFORNIA.

	1905.		1906.	
	Quantity.	Value.	Quantity.	Value.
Gold	911,217 oz.	$18,808,545	906,182 oz.	$18,732,452
Silver	1,076,171 oz.	50,009	1,220,611 oz.	817,830
Copper	16,697,544 lb.	2,604,816	28,726,448 lb.	5,522,712
Lead	147,723 lb.	21,043	338,718 lb.	19,307
Zinc			206,000 lb.	12,566
Total		$22,174,413		$25,104,867

averaging $2.22, and of lead ores 1681 tons, averaging $7.03, were produced.

There were 27 counties in California reporting gold product from deep mines and 24 reporting output from placers of different kinds. The quartz gold amounted to $11,356,527, and that from the placers $7,375,925. Most of the deep (or quartz) gold came from silicious ores—$11,036,018, but $318,489 was recovered in the treatment of copper ores, $1020 from the lead ores, and $1000 from the zinc ores. Calaveras had the largest tonnage of ore, namely, 583,207 tons; and Amador produced the most

Map of Northern California.

concentrate—11,281 tons, yielding $850,214, which came from 577,599 tons of crude ore. In the counties along the Mother Lode, that is Amador, Calaveras, El Dorado, Mariposa, and Tuolumne, there were 131 productive deep mines and 63 placers reporting in 1906. Three of these were copper mines, two of which also produced gold and silver. There were in these five counties 1,537,761 tons of ore produced, yielding a total of $6,488,327 or an average of $4.22 per ton. The placers of these counties yielded $315,303; and the copper output was $957,984.

The quartz mining counties of the State generally did not produce as much gold in 1906 as in the previous year, while those counties in which placer mining predominates show an increase. In 1905 the quartz gold amounted to $13,006,469 and in 1906 to $11,356,527, the reduction in output of gold from this source being $1,649,942. The placer gold in 1905 was $5,892,076 and in 1906 it was $7,375,925, an increase of $1,483,849 for the year. As to gold from placer mines, the total amount for the year is $7,375,925. Of this gold, the dredges produced $5,098,359. The 246 hydraulic mines yielded $1,051,172; the 104 drift mines, $605,817; and the 260 surface placers yielded $617,577.

The importance of dredging operations in California is shown in the following table:

OUTPUT OF GOLD FROM DREDGING OPERATIONS.

County.	1905.	1906.
Butte	$2,261,888	$2,768,782
Calaveras	202,505	177,112
Sacramento	610,672	921,300
Siskiyou	7,111	26,000
Trinity	5,000	
Yuba	188,967	1,205,165
Total	$3,276,143	$5,098,359

The drift mines of the State yielded $209,423 less and the surface placers $207,978 less in 1906 than in 1905, a total of $417,401 less. But the hydraulic mines yielded $79,032 more than in the previous year and the dredges $1,822,218 more, so that the total increase from placers is $1,483,849, this increase coming mainly, as shown, from dredging.

Of the total gold output of the State the deep mines yield 64.3%. Of the total placer mining output the

dredges yield 69.1%; the hydraulic mines 14.3%; the surface placers 8.3%; and the drift mines 8.2%. This shows that the dredging operations now far exceed in yield that of the hydraulic, drift, and surface placers combined. The dredges produced $2,820,793 more gold than all the other kinds of placer mining combined. The dredges produced 27.2% of the total gold output of California.

Butte county is now for the first time the largest producer of gold in the State, the amount being $3,016,717. Nevada county, for many years the leader, produced $2,658,420. Thus the stamps of Nevada county surrender to the dredge-buckets of Butte county in supremacy of gold output for the year 1906. The largest output from hydraulic mines is from Trinity county, with $361,102; from surface placers, Placer county, $130,222; and from drift mining, Placer county, $201,076.

As to silver, the total output of the State for 1906 was $817,830, which is $167,821 more than in the previous year. Of this $506,705 was derived from copper mines, $252,151 from silicious ores, $28,082 from placer mines, $10,792 from lead ores, and $20,100 from lead-zinc ores. The increase is derived from the copper and zinc ores. The counties of Del Norte, Fresno, Inyo, Madera, Mariposa, Monterey, Nevada, Plumas, San Bernardino, San Diego, Sierra, Trinity, Tulare, and Tuolumne, show a

combined decrease of $71,196 for the year, the largest deficit being in Inyo county. Those counties showing an increase of silver are Amador, Butte, Calaveras, El Dorado, Humboldt, Kern, Mono, Orange, Placer, Riverside, Sacramento, Shasta, Siskiyou and Stanislaus, Ventura, and Yuba, the total increase being in these counties, $339,017. The largest increase is in Shasta county ($271,083), which is due to increased output of copper ore.

The mines of California in 1906 yielded 28,726,448 lb. copper valued at $5,522,712, an increase in pounds of 12,028,904, and in value of $2,917,896. The increase in Shasta was $2,648,506; in Calaveras, $384,293; in San Bernardino, $91,001; and in Amador, $109; total increase in these counties, $3,123,909. Counties showing a decrease in output of copper were El Dorado, $24,960; Fresno, $136,640; Inyo, $22,851; Mariposa, $1956; Orange and Placer, $18,691; Plumas, $166; and San Diego, $749; total, $206,013. The expansion of operations in Shasta is wholly responsible for this marked increase in copper product.

In lead there was a decrease of $9186 for the year; and an increase of $5700 in Orange and Placer counties, and $1750 in San Bernardino. The total decrease was $1736.

For the first time zinc was produced in California, the value of the output having been $12,566.

It is to be noted that while the gold output of California declined in value in the small sum of $166,093, and the lead $1736, the silver increased $167,821, the copper $2,917,896, and the zinc $12,566, a total of $3,098,283. This makes the total output of California in all these metals $25,104,867 for the year 1906, which is an increase over the previous year (with platinum omitted in both years) of $2,930,454. For this increase in value, it will be noted, copper is mainly responsible.

PRODUCTION OF LEADING COUNTIES.

AMADOR, which is on the Mother Lode, shows a reduction of $158,035 for the year. The falling off in gold output was $159,785, but there was a small increase in silver and copper. The following statement shows the output for the past two years:

Year.	Gold.	Silver.	Copper.	Total.
1905	$2,420,161	$12,938	$1,560	$2,434,65
1906	2,260,376	14,579	1,669	2,276,62

Twelve deep mines report product, and some of these are being worked at great depth. The vertical shaft of the Kennedy is 3100 ft. deep; the Argonaut is 2700 ft. on the incline; and the shafts of the Central and South Eureka mines are 2500 ft. on the incline. The milling capacity of the county is 420 stamps. The principal producing mines are the Bunker Hill and Keystone at Amador City; Fremont Consolidated (Gover) at Drytown; Argonaut, Kennedy, Oneida, and Zeila at Jackson; and Central and South Eureka at Sutter Creek. The Oneida at Jackson has been given up and will no longer be worked. The Wildman and Mahoney mines at Sutter Creek have made no yield of late, not having been worked. The 579,569 tons of ore milled yielded $2,230,620 in gold and $14,401 in silver. The concentrate from this ore yielded $844,024 gold and $6190 silver from 11,281 tons.

BUTTE shows an increase of $435,861 gold and $4,265 silver. The total yield of the county was $3,016,747 gold and $10,853 silver. Butte is now the leading gold producing county of the State. This is entirely due to the operation of the dredges at Oroville. The quartz mining industry of the county is now of small importance, only 682 tons of ore having been worked in 1906, with a total yield of $6721. These quartz mines are at Berry Creek and Lumpkin, and are all small ones. Placers of different kinds are being worked at Bangor, Berdan, Berry Creek, Brush Creek, Cherokee, Clipper Mills, Enterprise, Forbestown, Inskip, Lumpkin, Orloff, Megalia, Nimshew, Oroville, Pentz, West Branch, and Yankee Hill. There are 56 producing placers, including 5 hydraulic mines 12 drift mines, 24 surface placers, and 15 dredging companies. The hydraulic mines in this county yielded $37,220 gold, drift mines $102,908, surface placers $101,207, and dredges $2,768,782.

The following table shows the output of gold from dredging operations at Oroville in the past few years, and the annual increase:

Year.	Yield.	Increase.
1903	$1,329,998	
1904	1,632,507	$302,509
1905	2,261,887	629,380
1906	2,768,782	506,895
Total	$7,993,174	$1,438,784

The number of dredges is increasing at Oroville, but other parts of the State are also showing profitable dredging areas. Most of the dredges are now landlocked, that is, none of the tailing material is allowed to escape into the rivers, but is impounded or enclosed with walls of cobbles and rock thrown up by the stackers.

CALAVERAS shows a falling off of $136,251 in its gold output for the year, but the copper has increased by $384,293, and the silver by $10,261, a total increase of $258,303, as the following table shows:

Year.	Gold.	Silver.	Copper.	Total.
1905	$1,780,185	$63,838	$572,022	$2,416,345
1906	1,644,234	74,099	956,315	2,674,648

The copper output is rapidly increasing. Over two-thirds of the copper came from Campo Seco and the balance from Copperopolis. Nearly 45,000 tons of ore were smelted in 1906. This copper ore yielded $59,294 in gold, and $65,138 in silver. These mines have their own smelting plants at the properties. The silicious ore from the quartz mines amounted for the year to 538,566 tons, yielding $887,918 gold, and $4971 silver. There were 32 deep quartz mines producing this ore. The increase in tonnage in the county for the year was 35,235 tons, including copper ore. Of concentrate there was 10,039 tons, yielding $473,295. Calaveras had the largest tonnage of any county in the State in 1906, the amount being 583,207 tons of ore.

The principal producing quartz mines are the Angels Quartz, Lightner, and Utica at Angels; the Gwin at Gwin mine; the Melones at Melones; and the Sheep Ranch at Sheep Ranch. Most of the other quartz mines were comparatively small producers. The copper properties are the Penn Chemical Works at Campo Seco and the Union Copper Co. at Copperopolis. There are 478 stamps operating in the mills of the county. The placer yield of Calaveras was $227,017, the larger proportion of which was from dredging operations at Jenny Lind and Wallace. There is very little surface placering, but the hydraulic and drift mines are productive, there being 14 placers in all, including two dredge enterprises.

NEVADA has been the leading gold-producing county of California for many years, but in 1906 its gold output was exceeded by that of Butte. It is still, however, the leading producer of gold from quartz mines. The production for the past two years was as follows:

Year.	Gold.	Silver.	Total.
1905	$3,076,997	$24,842	$3,101,839
1906	2,658,420	24,219	2,682,639

Fifty-six mines reported product in this county, 32 quartz and 24 placers. Of the latter the 7 hydraulic mines yielded in gold $117,724; the 8 drift mines, $135,182, and the 9 surface placers, $11,105, a total of

$264,011 from gravel. The ores treated were all from gold mines and amounted to 276,602 tons, which is 48,664 tons less than reported the previous year. From this ore were derived 4,912 tons of concentrate, which yielded $284,759. The total quartz gold, including this, was $2,394,409 and the total quartz silver $22,805. This shows that the average value of the ore milled in the county was $8.74 per ton.

The most productive quartz mines in the State are in the Grass Valley district, in which are included both Grass Valley and Nevada City. The returns for the past two years from the quartz mines were as follows:

	—Grass Valley.—		—Nevada City.—	
Year.	Gold.	Silver.	Gold.	Silver.
1905	$2,041,447	$10,483	$440,236	$12,531
1906	2,196,990	16,516	133,031	5,755

Aside from the reduction in output of the gravel mines of the county, this table shows that the decrease in yield of gold for the year was largely in the mines around Nevada City. The two largest mines at that point were inactive during 1906 owing to litigation, but lately operations have been resumed. The most productive gold quartz mine in the county—and in the State—is the North Star at Grass Valley. Other productive mines at that place are the Brunswick, Bullion, Central, Empire, Sultana, Idaho-Maryland, Pennsylvania, New York-Grass Valley, and Spring Hill. At Nevada City the producers are the Glencoe & Freeman, Gold Flat, Home Gold, Murchie, and Pittsburg.

At Graniteville are a few small producers, and others are at North Columbia, Rough and Ready, and Washington.

The largest producers among the auriferous gravel mines are the Esperance drift mine at French Corral; Liberty Hill hydraulic at Lowel Hill; Blue Tent at Nevada City; North Bloomfield and Union Blue at North Bloomfield; Waukeshaw at Relief; Badger Hill or Cherokee, Kate Hayes, Eureka Lake, and Yuba Canal at North San Juan; and Omega at Washington.

SHASTA shows the remarkable increase of $3,031,995, due to the resumption of active operations of the Mountain Copper Co., and the enlarged output of the Mammoth and other copper enterprises in the county. The record of the past two years is as follows:

Year.	Gold.	Silver.	Copper.	Total.
1905	$706,738	$163,400	$1,689,615	$2,559,753
1906	819,141	434,483	4,338,121	5,591,748

The county is thus by far the largest producer in the State, considering the gold, silver, and copper combined. It illustrates the importance of copper mining as a productive industry. Of the 30 deep mines producing gold in the county, 17 are deep gold mines, 9 placers, and their combined output is $819,144, yet the value of the copper from the four mines of that metal exceeds the gold by $3,518,977, which figure, in itself, is larger than the entire mineral output of any other county in the State.

The entire tonnage of the county was 327,482 tons, yielding a total of $5,591,748. Of this 22,897 tons of ore were milled, yielding $277,705 gold and $2195 silver. In this ore were 152 tons of concentrate, which yielded gold $12,871 and silver $217. The output from milling ores was $290,579 gold and $2412 silver, a total of $292,991. From 304,585 tons of smelting ores, the output was $518,705 gold, $132,009 silver, besides the copper. The copper ore amounted to 262,388 tons, yielding $1,338,121 in that metal, aside from the gold and silver. The quartz and smelting ores produced a grand total in gold, silver, and copper of $5,581,826. The placers in the county only yielded $9860 gold and $62 silver, a total of $9922.

It should be understood that large quantities of siliceous ore, carrying gold and silver, are used as flux in the copper smelting furnaces. In fact, one reason for the prosperous condition of the gold quartz mining industry in Shasta is because so many miners are working properties on which they do not have to erect reduction works, but sell the ore direct to the copper smelting companies, receiving returns in proportion to the assay-value. These smelting companies also obtain some ore from adjoining counties, and of late, have made purchases in southern Oregon.

The most productive copper mining enterprise in the county at present is the Mammoth Copper Mining Co., with smelters at Kennett. Other large copper producers are the Mountain Copper, with smelters at Keswick, in Shasta county, and Bulls Head Point, in Contra Costa county; the Great Western Co., with a smelter at Ingot; and the Bully Hill Co., with a smelter at Winthrop. The prominent producers of quartz gold are the National, the Original Quartz Hill, and the Utah & California at Buckeye; the Hazel (Gladstone), Brunswick, and Black Tom (Niagara) at French Gulch; the Midas at Knob; the Gambrinus and Mad Ox at Stella; and the Evening Star and the Reid at Whitehouse. Outside of the copper companies, the largest producer in the county is the Hazel Mining Co. at French Gulch. The increase in tonnage in this county (113,446 tons) is the largest of any county in the State.

TRINITY shows a falling off in its gold product of $215,192 as compared with the year 1905, and there was also a small reduction in its silver output. This is a county where mining for auriferous gravels is the predominating industry. Of the gold output of $560,843, the sum of $413,679 came from placer operations, while the quartz gold was only $147,164. The gravel mines, therefore, yielded $266,515 more gold than the quartz properties. There are 67 gravel mines reporting product, of these 41 are hydraulic mines, which yielded $361,102 in gold; 2 drift mines, yielding $2000; and 21 surface placers, with an output of $50,577. As regards hydraulic mining, Trinity has the largest output of any county in the State. Its 41 mines of this character yielded over $100,000 more than the 100 hydraulic mines of Siskiyou, which comes next in rank in this class of mining. In these two counties there are no restrictions upon hydraulic mining as there are in the counties in the drainage basin of the Sacramento and San Joaquin rivers, where the tailings have to be impounded. The most productive and largest hydraulic mine in the State is the La Grange, near Weaverville. Other large hydraulic mines are the Hupp at Weaverville; and the combined Chinese mines at the same place; the Bennett at Douglas City; the Sykes at Trinity Center; Chapman & Fisher at Junction City, and the Burger at the same place; the Butler (Old Unity) at Minersville, and combined Chinese mines at the same place. All these mentioned made an output of over $10,000 in 1906.

The yield of silver from these gravel mines was only $1731, and the yield of silver from the quartz mines of the county was $1250. There are no large quartz mining operations in the county and the yield from this source appears to be falling off. The tonnage for the year 1906 was only 9261, a falling off of 31,207 tons for the year. It was all silicious ore; about 300 tons of concentrate was worked. The principal quartz mines are the Five Pines at Trinity Center; the Brown Bear at Deadwood; the Globe at Dedrick; the Bullychoop near the Shasta line; the Oro Grande at Carrville. Other smaller quartz operations are conducted at these points and at Coleridge, Denny, Dorleska, Douglas City, and Lewiston. No copper is yet being produced in the county, but several mines of this metal are being opened or developed.

NEVADA.

By CHARLES G. YALE.
Statistician to the United States Geological Survey.

*As the total value of the gold, silver, and associated metals produced in Nevada in the calendar year 1905 amounted to $9,453,114, and in 1906 to $15,714,442, it will be seen that the State showed the very marked increase for the year of $6,261,328. Moreover, there was a decided gain in the value of every one of the metals, the most notable, as was to have been expected, in the gold, namely, $5,200,885. The silver increase was considerably over half a million dollars, and the copper about a quarter of a million dollars, and both lead and zinc show satisfactory advances.

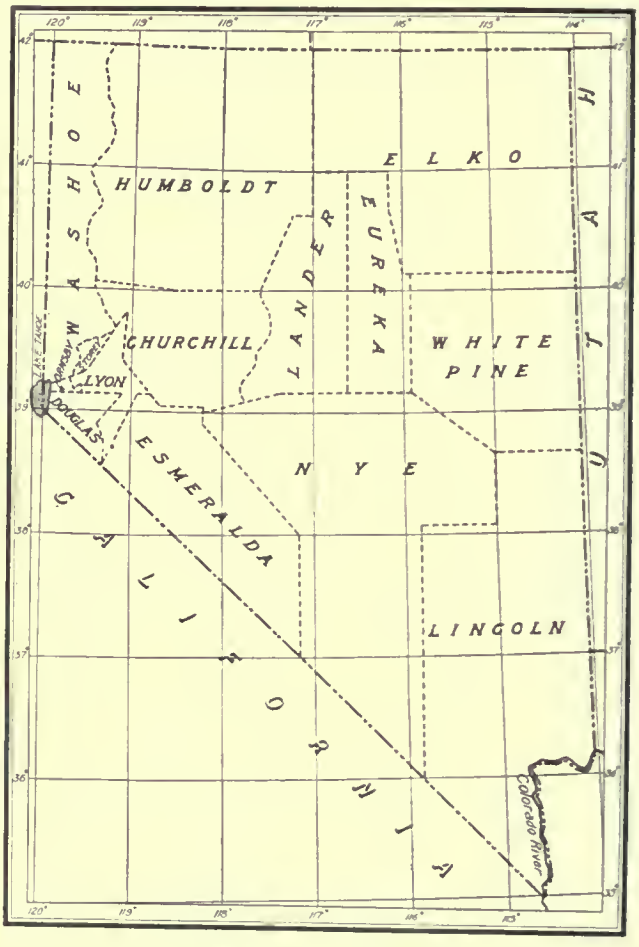
Although Nye county was much the largest producer in the State in 1905, and increased its output in 1906 by $685,620, yet it now takes second rank, giving the first place to Esmeralda, which has a total output for the year of $7,295,543. Of this $7,125,119 is gold, and of this total the amount of $7,026,154 came from Goldfield alone, which also yielded $10,484 in silver. The increase in production of this camp over the previous year was $5,148,499. The increase at Tonopah, in Nye county, was $672,803. The only other county of the State with a record for the year of over a million dollars is Lincoln, which yielded $1,506,056.

It may be proper to note that while the figures quoted show a very marked and satisfactory increase in bullion production, and indicates material progress in the condition of the mineral industry of the State, it is doubtful if they will be acceptable to many engaged in mining stock transactions who have led the public to believe that millions of dollars are coming monthly from the mines in the newer camps. To those engaged in legitimate mining enterprises, however, who know the time required to bring even the best of mines to the stage of development when steady and regular production may be expected, the showing is most satisfactory. The grade of ore yielded by certain of the mines of the State has been remarkably high, considering the quantities shipped, and as these shipments have been published when the ore was hoisted and sacked, again when actually shipped, and still again when returns were received, exaggerated ideas as to the weekly and total output of certain prominent mines prevail generally. Nevada has doubtless attracted more attention from miners, prospectors, and investors during the past few years than any of the other mineral-producing States of the Union. That it has 'made good' may be admitted; and it may also be taken for granted that everything indicates a still further and more marked increase in output as other mines are brought to a productive stage, and other camps are developed.

Nevada has two decided advantages from a mining point of view. It really has numerous mines of merit, and what is about of equal importance it has plenty of capital ready to develop them. After a long period of depression in mining affairs, and a gradually decreasing yield, the discoveries in the southern portion of the State a few years ago, once more attracted general attention to the possibilities of the mineral region. These camps were very rapidly developed, permanent towns established, railroads built, and a large population settled in what was heretofore desert territory. A natural result of these changed conditions was the revival of older camps, and their rehabilitation. Many of the old centres of mining, prosperous a quarter of a century ago, had been virtually abandoned and the mines closed. Lack of capital, and of suitable means of ore reduction and transportation brought about this result. As the success of the newer camps became manifest, population increased and capital for investment became plentiful. Then men began to investigate properties in the older camps of the State where there were numerous partly developed mines lying idle. Nearly all of these older localities are now being exploited to a greater or less degree. Moreover, not only are silver and gold being sought, but it is found that Nevada is rich in copper, zinc, and other metals, and mines of this character are being sought for, developed, and equipped.

Of course, the newer localities where the mines proved rich, and afforded opportunities for prospecting, mining, and investment in a virgin tract of country, naturally won the most attention. And it is from those new camps that the bulk of the bullion production of the State is now being derived and whence the most material increase of the future is to be expected.

In exemplification of this, it may be stated that over 77% of the entire bullion output of the State in 1906 came



The Counties of Nevada.

from the two camps of Goldfield and Tonopah; and that Goldfield alone produced nearly 45% of the total yield. This statement shows clearly the importance of the new camps, and it shows also why these two camps have had such an influence in bringing population and capital to the State. Much of the money derived from the new mines is being invested in developing properties at other points in Nevada, and outside capital is doing its shar also.

While more or less leasing is still going on, the larger productive mines are now worked solely on owner's account, the leases having expired, and not having been renewed. In this connection it is proper to make some mention of the so-called 'high-grading' in the mines that carry the richest ore at Goldfield. In the opinion of the officials of the most prominent mines, the ore stolen by the 'high-graders' amounted in 1906 to $1,250,000, of

*Abstracted from 'The Mineral Resources of the United States.' *lendar year 1906

which about $250,000 was ultimately recovered. This leaves a million dollars worth of ore presumably still secreted and as yet unmarketed. Of course, this amount is not included in the statistical tables.

Aside from Goldfield and Tonopah most of the newer camps of the State were only small shippers in 1906, although much development was accomplished. Some mines that were in a position to ship ore were awaiting the completion of railway lines; while others were holding their ore until in a position to mill it themselves. The San Pedro, Los Angeles & Salt Lake railroad is now completed from Las Vegas, in Lincoln county, to Bullfrog, in Nye county, and will open up a large mineral region. The Western Pacific line will also soon be completed in the western part of Nevada and will put many properties in White Pine county on a shipping basis. The completion of the Nevada Northern railroad from the main line of the Southern Pacific to Ely has already proved of the greatest advantage to the many low-grade copper properties being developed in that vicinity.

There is also some indication of the Nevada Central railroad, which runs from Battle Mountain to the old camp of Austin, being extended south through the Reese River district to the Round Mountain and Manhattan districts, in the northern portion of Nye county. The developments at Fairview and Wonder would also seem to warrant the construction of a branch railroad from Hazen, on the Southern Pacific, to these camps. The completion of the Tonopah & Tidewater railroad will give a second outlet to the camps in southwestern Nye and Esmeralda counties.

Although there were only 143 deep mines reporting product in the State in 1906, they yielded 496,307 tons of ore. The dry or silicious ores amounted to 163,672 tons (an increase of 42,268 tons), of an average value of $32.37 per ton. The 5,184 tons of copper ore averaged $5.84 per ton in gold and silver; and the 18,940 tons of lead ore averaged $13.51 per ton in gold and silver. There were also 8,511 tons of zinc-lead ore worked. Altogether the increase in tonnage for the year is 64,105. The amount of concentrate produced was 1,395 tons, worth $440,375. In addition there were 67,387 tons of old tailing worked, yielding $170,995. These were nearly all from the Comstock.

In 1906 there were 155 producing mines in Nevada, 143 deep and 12 placers. Two of the latter are hydraulic and the others surface placers. Of the deep mines, 75 have gold as the principal metal, 34 silver, 6 copper, 26 lead, and 2 zinc-lead. There have also been received reports from 1,070 non-producing mines. Of these, Nye county has the most—271, followed by Esmeralda with 193, Lincoln with 171, and the other counties with smaller numbers.

Furthermore, Eureka county produced 1,014,244 lb. of lead, worth $57,712, and Lincoln 948,830 lb., worth $52,088, the entire State yielding 3,823,617 lb. of lead, worth $217,549. In zinc the total output was 2,886,328 lb., worth $176,066, nearly all of which came from Lincoln county.

As to the source of the gold produced, with the exception of 2,556 oz. from placers, 127 oz. from copper ores, and 31,160 oz. from lead ores, it was all extracted from silicious ores. By far the largest part was derived from the mines at Goldfield. As regards the silver, the placers yielded 1,296 oz.; copper ores gave 11,273 oz.; lead ores, 275,469 oz.; and zinc-lead ores, 391 oz. This leaves 6,452,182 oz. as having been extracted from silicious ores. Of the total amount of silver 5,739,852 oz. came from Nye county, mainly from the mines at Tonopah.

The producers at Goldfield in 1906 were the Combination Fraction, Florence, Gold Bar, Goldfield C. O. D., Goldfield Daisy Syndicate, Goldfield Consolidated (Mohawk, Jumbo, Combination), Goldfield Great Bend, Jumbo Extension, and Diamondfield Black Butte Consolidated. By far the largest part of the output was from the various mines of the Goldfield Consolidated Mines Co. In this district the output for the year was 59,628 tons of ore, which, on being treated, yielded $7,036,638, of which $10,484 was silver and the rest gold. Much high-grade ore was shipped, but the average value of the total amount treated was $118 per ton, of which $117.83 was gold and 17 cents silver. At the local mills 19,461 tons of ore were worked, and to the smelters 40,167 tons were shipped. The milling capacity of the camp will be much larger in 1907. It may be said generally that the camp is in a position largely to increase its output and will do so for some time to come.

PRODUCTION OF METALS IN NEVADA IN 1905 AND 1906.

	1905.		1906.	
	Quantity.	Value.	Quantity.	Value.
Gold, oz.	254,927	$5,269,819	506,520	$10,470,704
Silver, oz.	6,482,081	3,915,177	6,770,611	4,536,310

Total	506,520	$10,470,704	6,770,611	$4,536,310	1,625,985	$313,813

In Lincoln county, production is reported from the districts of Crescent, Ferguson, Eagle Valley, Pioche, Yellow Pine, and Searchlight. The largest and most important producers in the county, and one of the largest producers of gold in the State, is the Bamberger Delamar Mining Co., in the Ferguson district. In output of gold only two properties exceed it, those of the Goldfield Consolidated Mines and the Tonopah Mining Co. It handles, however, very much the largest tonnage of any property in the State, and the ore is crushed and cyanided at its own plant. Aside from Ferguson, the most productive district in the county is Searchlight, which yielded $519,785 in gold and $7,734 in silver. The companies making this production were the Cyrus Noble, Brockman (Duplex mine), Quartette, Southern Nevada, and Searchlight companies. Of the 15,668 tons of ore worked in the district in 1906, the Quartette company produced 23,346. Four of these companies have 10-stamp-mills, while the Quartette had a 20-stamp mill and 20 stamps were added in 1907. The shaft on this mine is 850 ft. deep, while the shafts of the others run from 250 to 500 ft. in depth.

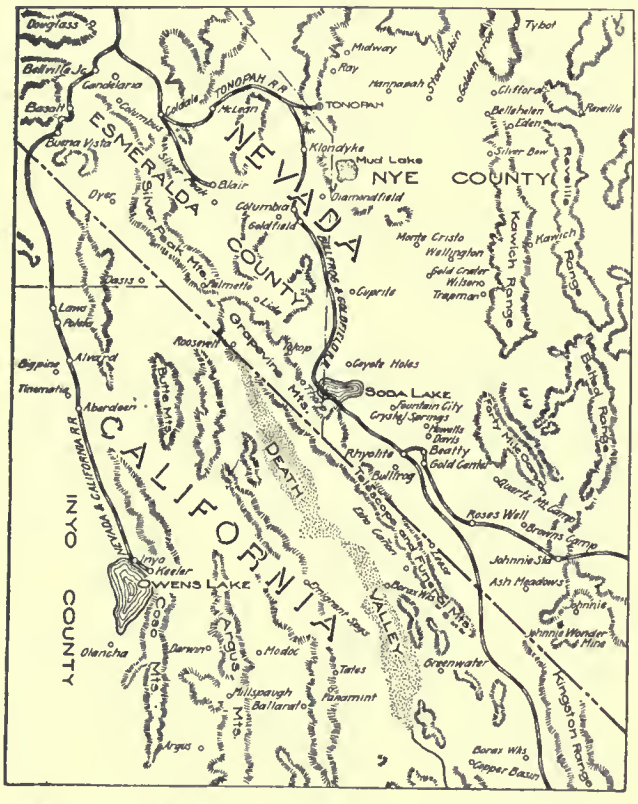
The Clark railroad has given new life to the old district of Pioche and to Yellow Pine. The only prominent producer in Pioche was the Bristol Consolidated Copper Co., which shipped a large tonnage of ore carrying silver, copper, and lead. The principal producer in the Yellow Pine district was the Potosi Zinc-Lead Co., which is the largest producer of zinc in the State.

The principal district in Nye county is Tonopah, which is second only to Goldfield, in Esmeralda county. The producers at Tonopah in 1906 were the Jim Butler, MacNamara, Montana Tonopah, Tonopah North Star, Tono

pah Belmont, Tonopah Extension, Tonopah Midway, Tonopah, and West End Consolidated companies.

The amount of ore treated from this camp in 1906 was 106,491 tons, yielding in gold $1,304,677 and in silver $3,817,612. This shows the average value to be $48.10, of which $35.85 is silver and $12.25 gold. All the ore from the camp in 1906 was shipped to smelters except that portion sent by the Tonopah Mining Co. to Chas. Butters & Co. at Virginia City for cyanide treatment. Over two-thirds of the silver output of the State came from Tonopah. The tonnage would have been greater had the companies been able to get sufficient cars, but the railroad was crowded beyond its capacity.

Shipments of ore from Bullfrog were comparatively small in 1906. Those reporting production were the Montgomery Shoshone, Skookum Bullfrog, Gibraltar Consolidated, and Tramps Consolidated companies. The



Map of the New Mining Districts of Nevada and California.

Berlin mine in Union district had a smaller output than usual. The new district at Fairplay had many active mines, but the only shippers were the Griggs Attwood, Attwood, and Pactolus companies.

The mines of the Comstock in Storey county yielded only $327,766 in gold and $185,763 in silver from 15 different mines.

The production of Nevada in 1907 is estimated at $15,000,000 of gold and 6,000,000 oz. silver.

ELECTRICAL POWER IN ARIZONA.—The successful organization of the Arizona Power Co. of Prescott, Arizona, is announced by R. S. Masson, associated with F. S. Viele, of New York. Immediate construction of the first power-generating plant will begin on Fossil creek, where 7500 hp. will be generated to supply the power and lighting contracts already made with the United Verde mine and the Humboldt smelter. The transmission lines of this company will pass through the centre of that extensive mining territory between Jerome and the Bradshaw mountains, and enough power will eventually be transmitted to supply all the mines and mills in this region. The Electrical Operating & Construction Co. will superintend the building of the different power plants.

ALASKA.

A. H. Brooks, chief of the United States Geological Survey's division of Alaskan mineral resources, has just returned from Alaska, and reports that various unfortunate conditions have led to such a curtailment of gold mining in Alaska during the last summer as to result in a material reduction in the gold output as compared with that of the previous year. Accurate statistics will not be available for several months, but the preliminary estimates indicate that the value of Alaska's entire gold production for 1907 will be between $17,000,000 and $18,000,000, as against more than $21,000,000 last year. This loss must be charged for the most part to the decrease in the production of the placer mines.

It is not to be supposed, however, that Alaska's placers have passed the zenith of their production. All the evidence points to the conclusion that a greater annual production than that of 1907 will yet be attained. The mining industry has therefore received only a temporary setback, but it is one from which it may not recover in less than a year or two. Mr. Brooks says:

The curtailment of placer operations can be assigned to certain definite causes, of which the difficulty of obtaining adequate labor is the most important. The Fairbanks district is the one that suffered most from labor troubles. A strike was started there on April 27, just when the gravel accumulated by the winter mining operations was ready to be sluiced by use of the water of the spring freshets. As a result many of the winter dumps were not finally washed out until fall. This not only prevented the mine operators from continuing work, but also put many of the smaller operators into financial difficulties, because they had counted on the winter production to finance the work during the summer. Labor conditions in the camp gradually adjusted themselves during the summer, but throughout the open season there was lack of experienced miners. When the strike began about 1200 men, it is said, left Fairbanks, most of whom started for the newly discovered Innoko district. As a result very few new enterprises were begun, and many of the established mines were not operated during the summer. Had there been laborers enough the Fairbanks district would, no doubt, have produced more gold in 1907 than it did in 1906. As a matter of fact its production was probably $3,000,000 less than it was in the previous summer.

Among last summer's important developments were the noteworthy production of Esther creek, the opening up of considerable placer ground on Vault creek, and the discovery of prospects on Eldorado and Our creeks. These discoveries, together with those on Smallwood creek, indicate that the Fairbanks district proper is more extensive than had been previously supposed. The finding of gold in an adjacent area, on the upper Chena river, is also significant, as this region appears to lie in the same general belt as the Fairbanks district.

The railroad from Fairbanks has now been extended to the mouth of Cleary creek, and this road and the numerous wagon roads that have been built make all parts of the district accessible. The high charges on freight from Puget Sound ports and the uncertainties and delays in its delivery still greatly discourage all mining enterprises. These discouragements can be removed only by the establishment of railroad communication with some coastal point.

Important developments were made in the Rampart district, notably in its southern part, on the tributaries of Baker creek, where two ditches were built and some successful hydraulic operations were carried on. Noteworthy, too, is the installation of three dredges in the Fortymile

district. Two of these were in operation for a part of the season.

Some excitement was caused by the discovery of placer gold at several points on the lower Yukon. While no great values were found, yet these localities are so accessible that they give promise of being mined at relatively low cost. The two largest stampedes of the season took place to the Chandlar river and to the Innoko. In the first locality at least one producing creek was developed and some good prospects were found at other localities. Of the Innoko less definite information is available. More than a thousand people took part in this stampede, and many claims were staked, but little systematic prospecting was done. The region is rather difficult of access, being several hundred miles from the Yukon by the Innoko river route. Some gold has been found, but it is too soon to predict what the future of this camp will be.

Seward Peninsula also had its labor troubles during the past summer. Though they were not so serious as those of Fairbanks, yet they considerably hampered mine operators, and as a consequence the production will probably be less than it was last season. The old beach-lines continued to be the centre of mining activity, though much of their extent has now been mined out. The second beach-line has been traced east of Nome river to Cunningham and Hastings creeks. The third beach-line has also been traced to Hastings and has been found west of Snake river at Sunset creek. There can be no doubt that the discovery of these rich beach placers has retarded the development of more extensive but less valuable creek and tundra placers. These ancient sea beaches have proved to be so very rich that mine operators are disinclined to spend their activities in preparing to work the lower grade deposits of other forms of placers. As a consequence, there has been but relatively little creek mining during the last two years in Seward Peninsula, especially in the vicinity of Nome.

In the northeastern part of the peninsula two long ditches, one at Candle creek and one discharging on the Keewalik, were completed. Considerable mining was done in this part of the peninsula, notably on Candle creek. The Taylor creek and some smaller ditches in the Kugruk district were also completed and were in part in operation.

The dredge on Solomon river has been in operation throughout the summer, as has also one near the mouth of Ophir creek. A smaller dredge has been operated on West creek, and a large dredge was constructed for mining on Bourbon creek near Nome. Gold dredging will undoubtedly become important in the peninsula. Plans are under way for utilizing water power and reducing the cost of operating the dredges.

Additional attention has been given to lode prospecting during the past summer, especially in the Nome district. Copper, lead, bismuth, antimony, and gold ores have been found, but it is too soon to predict an important future for lode mining.

In the Cook Inlet region the most notable developments were in the Yentna district, discovered in 1905. Here the operators are for the most part small holders, but in the aggregate considerable gold was produced. Work continued in the placers of the Sunrise district, but there were no noteworthy developments. Interest was aroused by the discovery of mineral-bearing lodes in Kenai Peninsula and in the islands and mainland to the southwest. Whether any of these are of commercial importance remains for the future to decide.

The mining of copper ore was continued at several localities in the Prince William Sound district, and considerable prospecting for copper was done. There was great activity in the Copper River region, especially in the Chitina copper belt. This region has been rendered more accessible by placing a steamboat on Copper river, above the rapids. The operations in this copper belt have been confined chiefly to making surveys for patents and to doing assessment work. It will be impossible to carry on any great amount of mining until the region is made more accessible by the railway.

The railroad situation in this part of Alaska has been the focal point of public interest throughout the summer. Construction work has been actively pushed by two companies building from Katalla, the immediate objective point being the coal deposit lying about 25 miles inland. In midsummer construction was also begun on a railroad from Valdez. All three of these roads claim to be building into the copper belt of the Chitina region.

Little has been done in the Alaska coalfields except to make surveys with a view of obtaining title to coal lands. The Controller Bay field will be opened up as soon as railroad transportation is established, and the same may be said of the Matanuska field.

In southeastern Alaska labor conditions again have trammeled mining operations. The Treadwell mine was closed for about three weeks early in the summer because of a strike, and the small operators have been affected to a lesser degree.

The copper mines of the Ketchikan district, which were being actively developed early in the summer, seriously felt the fall in the price of copper and some of them were forced to close. This was the case with the Hadley smelter and its subsidiary mining properties. Early in the summer five mines were shipping copper ore and a number of other properties were being opened.

FARADAY'S MIND was too absorbed in wonderment and almost religious fervor, as the secrets of nature revealed themselves, for sordidness in any form to find lodgment. He wasted his energy neither in money-making nor in captiously defending his discoveries and great conceptions from supposed infringement by other scholars. He never forgot, despite his brilliant original work, that generally the great investigators only lay the keystone in the arch which many less gifted workers have been erecting stone by stone. He did not consider it any detraction from his honor that he was permitted only to crown the structure which others had helped to build from the foundation up. They are the greatest among the great who appreciate this limitation and recognize what they owe to others. Faraday knew that his discoveries gave him but imperfect glimpses of some of the laws and phenomena of nature, which we, through our ignorance and prejudice, are slow in understanding, but which would soon cease to be secrets if we could only disabuse our minds of false conceptions, see facts as facts instead of as arguments for our theories, and then work together with single-heartedness.—James Douglas.

GOLD IN FRANCE.—Wells bored in Meurthe et Moselle have shown the presence of a notable quantity of gold and silver at a depth of about 800 ft. Some samples brought up with the cores have yielded 6 gm. of silver and 1 of gold per ton of mineral. These were taken from sandstones of Triassic age. From another boring, made by Mr. Francis Lour, during his interesting investigations in the Muschelkalk, at 1800 ft., beds of calcareous sandstone were met with which proved superior in yield to the average Transvaal gold-bearing rocks—that is, gave more than 8 gm. of the precious metal per ton. Further, considering that the mineral during calcination loses about one-fourth of its weight, it can be asserted that some specimens were worth at least £6 per ton. The gold is thought to have originated through the evaporation to dryness of the ancient Triassic sea.

Variations in Mining Costs.

Written for the MINING AND SCIENTIFIC PRESS
By J. R. FINLAY.

In examining a mine in southern Idaho I found that expectations were being based on a mining cost of $5 per ton. Upon studying the question to the best of my ability, I concluded that the ore could not be mined for less than from $20 to $25 per ton. This enormous discrepancy of course influenced decisively the transaction contemplated and laid emphasis on the importance of correct knowledge on this point. There were no figures at hand showing the experience of former operators. The aggregate value of the ore blocked out was about $1,000,000. I think it will prove interesting to analyze the considerations which gave rise to such a wide difference of opinion. One of the most vital features proved to be the question of the necessity and cost of development work.

It was assumed on one hand that advantage could be taken of the ore already available, and it was thought without any great attention being paid to the subject that a cost of $5 per ton would be ample for mere stoping. It was thought that the property could be paid for out of the ore reserves and, that object being attained, the development could safely be left to take care of itself, since any further ore would represent clear profit. In certain contingencies this view of the matter might be all right. If the development had proceeded to a point where it demonstrated that no further ore should be looked for, of course the only problem to consider would be to extract the ore in reserve as cheaply as possible.

This was not the case. The prospect of finding more ore was good and the profit to be made from the property depended on future discoveries. At the contemplated cost of $5 per ton for mining the profits to be expected would no more than cover the price of the property. If when the ore was exhausted the property were nominally paid for, it would be rather a vain triumph. In that event two unpleasant necessities would have to be faced:

(1) Shutting off production until more ore could be developed.

(2) Finding money for the development.

Under such circumstances the paying for the mine from o e reserves would indeed only be nominal. The correct stand to take was that the property must be considered as a permanent thing. Development must be provided for from the beginning. The mine could not be considered as profitable unless the ore already available could not only pay for stoping, but for finding more ore and for a number of other things that cost money.

The whole problem is a function of how the ore occurs in the ground and of the commercial conditions of the neighborhood in which it is situated. The occurrence of the ore was as follows: The veins were exceedingly persistent both in length and depth, but the ore-shoots would average only nine inches thick. The shoots moreover were short, of irregular outline, and were scattered along the vein for a length of about 2000 ft. As greater depth was attained, the vein itself must be reached by longer and longer adit-levels. On account of the vein consisting of a system of nearly parallel fissures, any one of which might be mineralized, it was necessary to crosscut a zone and in many cases run parallel drifts on the same level. Moreover, for purposes of ventilation as well as for exploration, raises had to be put up at intervals. In fact, not less than 15,000 ft. of openings had been made during the history of the mine to find and open up about 25,000 tons of ore. Just what this development cost I do not know, but it would probably average $12 per foot, or $180,000. Here we have a cost of, in round numbers, $7 per ton for finding the ore and getting it ready to stope.

It is pretty evident from the above that even were the estimated stoping cost of $5 per ton found to be correct, our real mining cost would be $12 per ton, adding the development.

But as a matter of fact a nine-inch seam cannot be stoped for $5 per ton in Idaho. It is to be remembered that the nine inches of ore must be kept carefully separated from the waste. When it is remembered that a stope can scarcely be worked that will not average at least 3½ ft. wide, it is evident that about four times, by weight, as much material must be handled as is taken out as ore. Moreover, the necessity of keeping the ore strictly separated from the waste makes it necessary to perform two separate acts in breaking and removing the ore and waste. It is probable that if all the material in a 3½-ft. stope were removed, the cost would be about $3.50 per ton, but when only one quarter of this material is ore, the cost of the ore will be $14 per ton. In my judgment, therefore, the mining of this material would stand thus far as follows:

Development	$ 7 per ton
Stoping	14 " "
Total	$21 " "

But even at this we have not in all probability arrived at the true mining cost. We have considered development and stoping costs as fully and properly worked out. I mean by this that we have not deceived ourselves by poor accounting, forgetting to add in the manager's salary or the office expenses. We have charged up every current expense against the operation. But what about expenses that are not current? I mean the amortization of the plant.

In this connection I think we should not charge the purchase price of the property. That price might be entirely out of proportion to its merits. I am trying to arrive at the real operating cost, which, of course, includes all expenditures made necessary in the process of working the mine. Machinery, offices, tramways, warehouses must be provided, and the cost of all these things must be returned with interest. It is quite easy to forget this fact in preparing a statement of stoping costs. It *is* forgotten, I believe, in 99 cases out of 100. In saying this I do not wish to convey the impression that so large a proportion of examining engineers overlook this point; but I do mean that as costs are generally discussed and figured by mining men, no heed is paid to anything except the current expenses.

The way to gain a correct idea of the usual confusion between part costs and real costs is to get the history of a number of mines for periods long enough to give a true average of results and obtain the whole cost by dividing the total expenses by the total tonnage. For instance, the reports of the Bunker Hill & Sullivan, a very well managed lead mine, for 20 years, give the following: 3,388,108 tons of ore were mined at an average operating cost of $2.60 per ton. Nevertheless, we find in the same reports that there were expended in the period, $3,400,000 in addition to operating costs, or $1 per ton. Since 20 years seems an ample space in which to depreciate all, or practically all, of the extraordinary expenses and the equipment of a mining property, it seems fair to me to charge up the total expenses in such a period to operating. Our real operating cost then has been $3.60 per ton instead of $2.60. Even admitting that $1,000,000 should still be held to capital account for future operations, the real cost should be $3.30 per ton.

The extraordinary nature and extent of the misconcep-

COMPARATIVE TABLE OF WORKING COSTS.

Southeast Missouri.	1900–1907	3,000,000	Concentrating	1.63	0.33	20	0.70	2.33	0.60	2.93	Development done by shaft sinking. Exploration by diamond-drilling.

tions of mining costs is illustrated in the most widely separated regions. Let us take the Cripple Creek district in Colorado. Messrs. Lindgren and Ransome in their U. S. Geological Survey report on that district state the gold output to the end of 1903 at $121,115,022. This came from about 3,500,000 tons of ore. When we come to examine the circumstances attending the extraction of this ore we find that it must have cost nearly if not quite $20 per ton. The figure is deducted as follows:

There had been done up to the end of 1903, outside of surface prospecting, about 150 miles, or 2,300,000 ft. of underground workings in the Cripple Creek district. In this total there was 80,000 ft. of shafts, which cost in all probability (with their equipment) not far from $75 per foot. This item would be $6,000,000. In addition to this, there were 2,200,000 ft. of drifts, cross-cuts, and

raises. These would easily cost on the average $10 per foot, or $22,000,000. Here we have a total of $28,000,000, or, in round numbers, $8 per ton merely for finding and getting at the ore. To this we must add at least $8 per ton for stoping the ore, $1 for sorting, and $2 to $3 more for amortization of plants, general expense, litigation, to bring up the total to about $20 per ton.

Freight and treatment on this ore would be about $10 more and our total cost is brought up to $30. The remaining $5 or $6 per ton was profit; which figures at about $20,000,000 in dividends. I may have estimated the mining cost a dollar too high and the freight and treatment a dollar too low, but the errors are immaterial.

At the present time undoubtedly better results, or lower costs, are being obtained at Cripple Creek. The mining costs probably do not exceed $13 per ton, but the ready explanation is that the former proportion of development work and construction work required to open up the mines is no longer done. This fact, together with the lower treatment rates, enables the mines to live on lower-grade ores. The profit obtained now is less than it formerly was, in spite of the lower costs, and it is perfectly certain that scarcely any of the mines could be operated on their present ores if they had to face the problem as it was when they were first developed.

To be sure a good deal of work has been done in the district that never paid at all. Still it can hardly be said that any large amount of work in the district was, in a mining sense, foolishly done. By far the greater portion of the 450 miles of openings was perfectly legitimate mining exploration. No one will deny that Cripple Creek has been, and is, a good district, which has added much to the gold of the country and has yielded large and well earned profits to its owners. Its 12 first and most successful years fell largely in a period of general depression when supplies were cheap and labor abundant and good; yet it cost $8 per ton to block out the ores. Many a manager has vainly tried to mine his ore at $8 per ton for everything. Some have done it perhaps for a while either by shipping waste to the mill or by neglecting development.

We turn to the reports of the Tennessee Copper Co. and find that the mining costs there have been only $1.43 per ton, as follows:

Exploration and development	$0.20	per ton
Mining and sorting	0.80	"
General expense	0.20	"
Amortization	0.23	"
Total	$1.43	"

This is the actual experience for the first five years of that mine.

At first it seems rather absurd to say that Cripple Creek mining was all right as against this record. Perhaps the Cripple Creek mines were not so well managed, for I believe few mines have had as good management as the Tennessee Copper Co., but they were legitimate, successful enterprises managed with at least an average degree of intelligence and skill. For equivalent work, taking into consideration the difference in wages, the performance of Cripple Creek is as good as that of Tennessee. The point I wish to bring out is that the fundamental differences in the conditions involves a difference of operating costs that are simply enormous and I believe that insufficient attention has been paid to the principles underlying these great differences.

In many cases the valuation of a mine depends upon a solution of the question of mining costs. If you can mine an ore for $30 per ton and sell it for $60 per ton you are doing just as good business as when you mine an ore for $3 and sell it for $6; but you will not be doing as good a business as you thought you would if you counted on mining a $60 ore for $3 per ton. The source of the greatest cost of high-grade ores is undoubtedly development work. High development costs are more particularly characteristic of non-concentrating mines. Concentrating ores usually occur in large bodies and, once found, can be developed at moderate cost. The stoping cost of a concentrate is apt to be higher than that of even the thinnest streak of hand-picked ore. In principle there is not much difference, but the concentrating mill often goes to greater extremes in selection than the miner does.

It will prove interesting to get the life histories of a number of mines. I have very few. It is difficult to find a series of reports that give the information required.

In the accompanying table I give some information gleaned from a number of published reports. The figures are not pretended to be exact, but in all cases they may be vouched for as pretty close approximations. The accuracy with which the true relations of cost are shown is proportioned to the length of the period covered.

The salient conclusion to be taken from these statistics is that in the majority of cases the costs given by mining companies, or at least popularly attributed to them, are too low, often by 30 to 50%. At least, this is the impression they make on me. The explanation of this is simple and contains nothing to the discredit of the companies that issue the reports. We may say that there are two causes for under-estimating, the first being that as the "oldest inhabitant" remembers some cold winters in his childhood and not the ordinary ones, he ends by believing that he lived in his youth in a more rigorous climate than the present, so the mine manager prefers to dwell upon the best showing that the mine has made and persuades himself that others less favorable are extraordinary. The second cause is that the later reports of a mine's operations seldom take cognizance of the large costs for plant and development incurred in the early stages. In other words, they forget that they are living partly on the surplus of former years.

In properties where there is no capital except the stock issued, where the mine pays well, where settlements are made promptly for cash, and where there is little to do in the way of finance except to see that there is enough cash kept in the treasury to meet the next payroll, there is no excuse for, and seldom is, any confusion as to how the property really stands. Here the treasurer may always know, in spite of any finesse the manager may have in the way of cost-keeping, just what the real costs are by the simple process of dividing his expenditures by the tonnage. But where capital is borrowed on bond or note issues, where the output must be held through a long process and financed, where you must figure on sinking funds and redemption funds to cover the capital invested in extensive plants, the problem is not so simple. In such cases the stockholder has the best reason for wanting to know what the real costs are; for if the cost of the year is to differ by 40% from the cost for the decade, his calculations are apt to go much more than 40% astray.

Another point is worth noting. The wide differences in costs of various mines in themselves prove that to the examining engineer this subject is of great importance. Is a partly developed property to be worked like the Treadwell or like the Portland? If the Wolverine were worked on the same costs as the Calumet & Hecla its copper would have cost to date 16 cents per pound instead of 8.4 cents. If the Calumet & Hecla were worked on the same basis per ton as the Wolverine, its copper would have cost about 4¼ cents instead of 8¼. Where experience on a big scale points to such divergences, there is a good field for insight.

Relation Between the Assay-Value of Mill Products and Smelter Contracts.

Written for the MINING AND SCIENTIFIC PRESS
By GELASIO CAETANI.

Do men running a mill always keep in mind the relation that exists between the assay-value of their product and the smelter contract under which the concentrate is sold? I hardly believe it, because smelter contracts are a wearisome kind of literature, hard to disentangle and painful to digest. The contracts are clearly worded, but the numerous discounts, penalties, and charges are at times so mysteriously complex, that it is hard to make out how much is taken out and how much left. Perhaps the smelters realize that a plain statement of the total discounts and charges would painfully impress the producer who has to sign the contract, and that it is far more humane to make him take his medicine by small spoonfuls than all at once. Any contract, however, can be expressed mathematically by a formula, and under such form be analyzed and discussed far more easily than a pageful of words.

To illustrate this, let us take as an example a contract for lead-silver ore, which we shall suppose to be worded briefly, as follows:

"The smelter is going to pay for 85% of the lead at 85% of the New York quotation, if the New York quotation is $4 or less per 100 lb. lead, and if the New York quotation is above $4, the smelter is going to pay for 85% of the lead at 85% of $4 plus one-third of the difference between $4 and the New York quotation.

"The smelter will also pay for 95% of the silver at 95% of the New York quotation.

"The freight and treatment charges will be $10 per ton of concentrate. If the concentrate assays below 45% lead, there will be an extra charge of 10 cents for each unit of lead below 45% and the reverse; if the concentrate assays above 45%, there will be a bonus of 10 cents for each unit in excess."

The contract is dual: (1) When the price of lead is below $4; (2) when $4 or more. We shall consider only the second case.

Let us adopt the following symbols:

P = Assay of concentrate in percentage of lead.
A = " " " " ounces of silver.
N = New York quotation for lead, in dollars.
Y = " " " " silver, in dollars.
V = Total net value of concentrate, in dollars.

The above contract can be expressed mathematically, as follows:

$$(1)\quad V = 0.85\,\frac{P}{5}\left(0.85 \times \$4 + \frac{N - \$4}{3}\right) + 0.95\,A \times 0.95\,Y - \$10 - \$0.10\,(45 - P)$$

Which formula can be reduced to:

$$(2)\quad V = P\,(0.45135 + 0.0566\,N) + 0.9025\,AY - 14.5.$$

This means that the smelter is going to pay $2.2567 plus 0.283 N for each 100 lb. lead, 90.25% of the silver, besides charging $14.50 for freight and treatment. If the price of lead be $5, the smelter will be paying for only $3.67 per 100 lb., or for 73.4% of the lead, besides charging $14.50 for freight and treatment.

To analyze further the contract, let us make a supposition that generally holds good for any one lead-silver mine, namely, that the silver ratio of the mill products be constant, and let us assume that in our case the concentrate contains one ounce of silver for each unit lead.

The formula (2) can then be reduced to:

$$(3)\quad V = P\,(0.45135 + 0.0566\,N + 0.9025\,Y) - 14.50, \text{ in which } V = 0 \text{ for } P = \frac{14.5}{0.45135 + 0.0566\,N + 0.9025\,Y}$$

and for N = $5 and Y = $0.65, we have

V = 0 for P = 11.0% lead.

This means,

That any product assaying below 11.0% lead is shipped to the smelter with loss.

We also see from formula (3) that

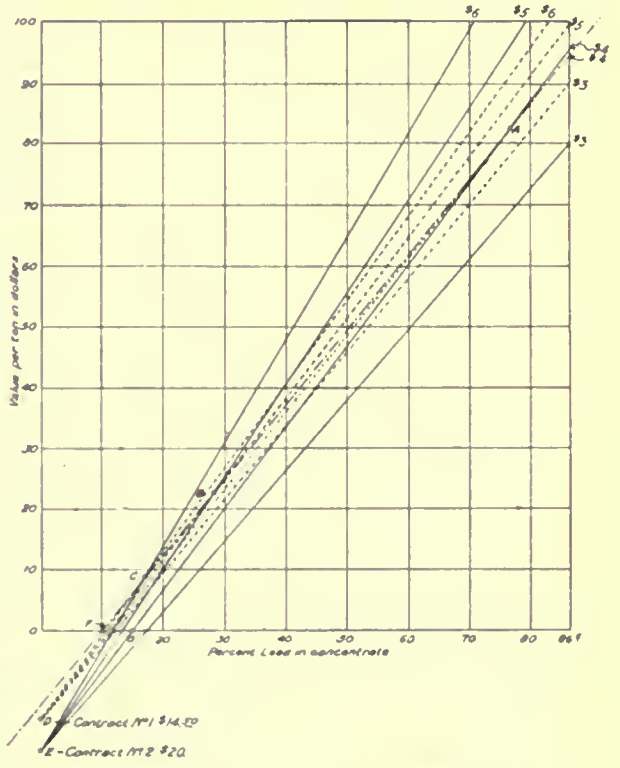
for P = 0, V = − $14.50.

This means,

That any barren sand shipped to the smelter represents a loss of $14.50 per ton.

Now let us take a mill product assaying P^1 in lead, and split it by means of a concentrating machine into two products, a high-grade product assaying P^2 and a low-grade one assaying P^3. The tonnages of the products may be called T^1, T^2, and T^3, and the following relations are known to exist:

Graphic representation of Contracts N°1 and N°2



$$(4)\quad T^1 = T^2 + T^3.$$

$$(5)\quad T^1P^1 = T^2P^2 + T^3P^3.$$

Such a separation is made in practice, for example, when re-treating a dirty Willley concentrate on a finishing table.

It is easily proved that:

The smelter contract value of the original concentrate is equal to the sum of the values of the two products sold under the same contract.

In fact formula (3) can be expressed by V = PC − D, in which C and D are constant, and if the above conclusion is correct we must have:

$V^1 = V^2 + V^3$, or $T^1\,(P^1C - D) = T^2\,(P^2C - D) + T^3\,(P^3C - D)$.

Substituting in this last formula T^1 by $T^2 + T^3$ we obtain formula (5).

The aforesaid is not true when a mining company is selling under two different contracts, or under a contract which is radically different for high-grade and low-grade concentrates. Both contracts have in such a case to be expressed algebraically and the two formulas equalled to each other. The value of P obtained from the equation will give the dividing point between the two contracts. There will be profit to split a concentrate in two products in such a way that the grade of the one

is above and the grade of the other below the dividing value found for P. The profit will be proportional to the difference between the grades of the products and the dividing value of P.

The three conclusions previously stated lead to the following further conclusions:

By eliminating from the concentrates any part of them assaying 11% lead we shall reduce the tonnage of the concentrates without diminishing their total net value.

This is important to be kept in mind where the concentrate is hauled a long distance to the railroad.

We can also say that:

By eliminating from a concentrate any part of it assaying less than 11% lead we shall reduce the tonnage and increase the total net value of the remaining concentrate.

I have known mines selling their concentrates under less favorable conditions than those of the contract I have taken as an example. By doing some figuring, more than one superintendent will be astonished to find out what a high-grade tailing he can profitably make. A low tailing is not by itself a proof of good milling, and in a general way we can say that the tailing can be higher when the market value of the metals is low.

Low-grade concentrates will result in low-grade tailings, but there is a point at which there is a greater loss due to unprofitable material shipped to the smelter than to the lead escaping through the tail-race. On the other side it may be said that high-grade concentrates are liable to cause undue losses in the tailings. This is especially true with fine slime. As an illustration, I may mention the slime that is treated on the vanners in the Bunker Hill & Sullivan mill in Idaho.

The vanner-feed assays about 19% lead and 9% silver. When the market value of lead is high the feed could be shipped directly to the smelter (if the smelter would accept such low-grade products), with greater profit than can be actually recovered by a single vanner concentration. By making a low-grade concentrate it is possible to obtain a shipping product without diminishing greatly the net profit per ton treated, but as soon as it is attempted to make a high-grade concentrate both the extraction and the profit decrease rapidly.

If the market value of lead falls to a certain value almost the same profit can be made by shipping the feed, as by making a high-grade or a low-grade concentrate. But for lead at, say, $3.50, it pays decidedly to make a clean concentrate.

I cannot follow here the multiple conclusions to be reached in milling by keeping in mind the relations that exist between the grade of the mill products and the smelter contracts. Conditions are different in each practical case, but one fact will be generally found to be true, namely, that it always pays to concentrate in two or three stages.

In the first stage of concentration the bulk of the ore handled is great, and the production of a high-grade concentrate will surely result in a heavy loss. It is well at first to make a low-grade concentrate and to re-concentrate with greater care, providing special means for re-treating the middling produced. The concentrates produced at this second stage have to be physically analyzed, and if they are found to contain some high-grade sand that cannot be separated from its included mineral and cannot be shipped with profit, it is well to make a third separation and to let part of the lead run down the creek to the advantage of the present and future generations.

Before closing the subject I may still say that any contract that can be expressed by a formula can be represented graphically. The contract expressed by formula (3) is represented by a family of straight lines having the point V = — $14.50, P = 0 in common.

This is shown in the diagram (Fig. 1), Y being supposed to be constant and equal to $0.65, and N variable, as has lately been the case. On the same diagram is also represented a second contract in common use for lead-silver ores, and which can be expressed by:

$$(6)\quad V = 90\%\ PN + 95\%\ AY - \$20.$$

Assuming the contract to be applied to the ore taken as the subject of this discussion, we can simplify the formula (6) to:

$$(7)\quad V = P(0.6175 + 0.18\ N) - 20.$$

Both contracts have been plotted on the diagram for values of N equal to $3, $4, $5, and $6.

We see from the diagram that:

(a) In the second contract the value of a concentrate is more strongly affected by the variations of the market value of the lead, than it is in the second contract.

(b) That for a certain value of N there is a value P^0 of P for which the value of a concentrate is the same under both contracts. All these points P^0 lay along the line marked A B C.

(c) All concentrates assaying higher than P^0 are sold to better advantage under the second than under the first contract, and the reverse, all concentrates assaying less than P^0 must be sold under the first contract.

The complete discussion of the diagram would lead us beyond the limits of this article, and I shall therefore not attempt to enter the subject more deeply.

There are other factors, besides the smelter contracts, which have to be taken into consideration in milling. They can be expressed by three words: Cost of production. By keeping all these factors in mind, milling can be brought close to its maximum economic efficiency, and if ever this point is reached it is well to look around once more to see whether we are right after all.

Tube-Mills on the Rand.

There are between 50 and 60 tube-mills at work upon the Rand. Tube-mills have come to stay on the Rand, as has been the case wherever they have been judiciously introduced. The place of the tube-mill in gold-milling is assured, but still their use is in a very unsettled state. There are many different kinds of lining, each with its advocates; similarly other matters connected with tube-mills are mooted questions. Recently Kenneth L. Graham ran a series of tests at the Geldenhuis Deep in which he used in one mill Danish pebbles, in the other pieces of common 'banket.' Both tube-mills were 22 ft. long by 5 ft. 6 in. diam., both were lined with silex blocks, and in both the conditions during the test were kept as nearly the same as was possible. The results of these experiments, extending over a period of a month, showed a distinct advantage in favor of the banket against the imported pebbles. Not only was there a saving in the cost of the banket compared to the Danish pebbles, but it appeared that the wear on the mill was less with the banket. Former less extended experiments on the Rand indicated that it was cheaper to use Danish pebbles. At Pachuca it has also been found that the use of the local supply of quartz is far cheaper than the use of imported pebbles. Hard 'nigger heads,' which occur in many quartz veins, are especially good for the grinders in tube-mills. This subject of using the ore itself as grinders in tube-mills is worthy of quite careful investigation elsewhere, especially as the saving at the Geldenhuis Deep was £13 for the month.

Precipitation of Copper From Cupriferous Waters.

Written for the MINING AND SCIENTIFIC PRESS
By FRANK H. PROBERT.

Seven years ago I was privileged to investigate the several methods of extracting copper from lean ores by wet processes at Rio Tinto and Tharsis, in Spain. Within the last year, while examining mines at Butte, Montana, my attention was called to the slipshod methods of winning some of the copper from the cupriferous mine waters and from Silver Bow creek. While at Butte I was struck with the very crude methods and appliances used and the low extraction obtained. It may be said that the copper waters cost the mining companies practically nothing and that the rough methods employed for the extraction of a percentage of the contained metal costs very little more, but if a slight modification of the plant and a little more attention to detail will insure a greater extraction at practically the same cost, after the installation of the plant, then I take it the subject is worthy of investigation. The question resolves itself into one of economies and it would probably not pay to remodel such precipitating plants as have already been erected, but since the waters of Silver Bow creek are a never-failing source of revenue to the companies over whose claims they run, it is worth while to ascertain the conditions and plant likely to insure a high rate of extraction. There are probably many other camps in which quantities of copper-charged waters are running to waste and as the following remarks and suggestions apply in all cases where cupriferous water is to be handled, a description of the practice may be welcome. I shall first of all briefly describe the Rio Tinto practice from the time the liquors, as the copper-laden waters are called, leave the ore-heaps until they are returned to other heaps for further work. The process is continuous. Then it will be my object to show how such steps in the process as are suitable may be applied at Butte.

The huge masses of ore in the province of Huelva, Spain, that are treated by this 'natural cementation' process, consist essentially of massive iron pyrite containing from a mere trace to 1% copper. The mineral as laid down in the heap for oxidation and subsequent leaching contains an average 2% copper. It is probable that this copper exists in the form of finely disseminated particles of chalcopyrite scattered through a matrix of iron pyrite. It is really a cupriferous pyrite. The ore is crushed to pass through a 2½-in. ring, it is mixed with about 30 % of finer material, and is then laid down in heaps covering an extensive area, about 30 ft. deep. The method of laying down these heaps and insuring a free

Precipitating Copper at Rio Tinto.

circulation of air through them at Rio Tinto has from time to time been described in the technical press. As it has little or nothing to do with the subject under discussion it is not necessary again to describe it. The heaps are irrigated continuously with water and spent liquors. The washing of the heaps serves three purposes:

1. To keep the temperature down.

2. To form ferrous sulphate and free sulphuric acid, which react to produce ferric sulphate; the latter acts upon the cuprous and cupric sulphides to form copper sulphate.

3. To dissolve the sulphate of copper formed and to carry it away from the heaps.

It is found that a crust of ferrous and copper sulphates sometimes forms an impervious layer on the top of the heap. When this happens an iron bar is inserted, the crust is broken up and turned over. The copper-charged waters running away from the heaps are now taken to the precipitating vats for treatment.

The fundamental principle underlying precipitation of copper from waters by means of iron is expressed in chemical terminology (1.) $CuSO_4 + Fe = FeSO_4 + Cu$, but

there are other reactions to be taken into consideration, as

(2.) $Fe_2(SO_4)_3 + Fe = 3FeSO_4$.

(3.) $H_2SO_4 + Fe = FeSO_4 + H_2$.

(4.) $Fe_2(SO_4)_3 + Cu = CuSO_4 + 2FeSO_4$.

The copper liquor as it leaves the heaps contains much ferric iron, which would (as is shown by equation No. 2) cause an unnecessary consumption of scrap iron. The ferric salt is reduced to the lower oxide before it enters the elaborate plant by passing it through a small heap of 'fines' of the raw ore, and the analysis of the effluent liquors shows that approximately 90% of the persalt is reduced to protosalt. The following table gives the analysis (in grams per cubic metre) of the entering and leaving liquors of the precipitation plant at Rio Tinto at the time I was there:

	Entering.	Leaving.	Entering.	Leaving.
Copper	2,710	19	2,780	19
Ferrous iron	13,908	17,202	14,030	17,934
Ferric iron	610	.....	732	.....
Free acid	4,874	4,129	4,991	4,349
Total solids	70,872	69,662	71,980	72,834
Specific gravity	105.818	105.718	105.901	105.972
Consumed iron	1.26	to 1 Cu.	1.26	to 1 Cu.

The best results are obtained when the solution is slightly acid, as it tends to accelerate precipitation and prevents a falling out of basic salts of iron while precipitation is going on.

The liquors are sampled every four hours at Rio Tinto at different points in their path through the vats, so that an absolute check is kept on the reaction. So perfect is the system that Mr. Hart, superintendent of the leaching plant at Tharsis, told me that the amount of copper, calculated from the solution, differed from the actual copper output from the vats during the period of 12 months by only 15 tons.

The precipitation vats are really a series of canals in which the liquors give up their copper. They are arranged in sets, each set consisting of from 4 to 6 vats. Both at Rio Tinto and Tharsis the liquor traverses about 3 kilometres before all the copper is precipitated. The vats are lined with timber 9 by 3 in., the joints being caulked with ropes to prevent leakage, and the whole covered with tar, pitch, or asphalt. The walls dividing each set of vats are made of rough stone or masonry, lined in the same way. There is a gradual fall through the series from start to finish. At Tharsis the inclination is as follows:

For the first 40% of the copper	1 in 200
" " next 30% " " "	1 in 150
" " " 20% " " "	1 in 100
" " remainder	1 in 50

Here follow the details of the vats at Rio Tinto:

Division	1 to 2.	7	vats	each	98	m.	long	by	1.22	sq.	m.	in section.
"	2 to 3.	2	"	"	70	"	"	"	1.81	"	"	"
"	3 to 4.	3	"	"	44	"	"	"	1.30	"	"	"
"	4 to 5.	3	"	"	125	"	"	"	1.28	"	"	"

In division 5 to 6 there is a parallel series about 65 sq. m. section, with a total length of about 1600 m. of shallow vats. Divisions 1 to 6 receive from 380 to 450 cu. m. of liquor per hour, assaying from 2600 to 3000 gm. copper per cubic metre.

The presence of ferric sulphate or free acid in the liquors causes an unnecessary consumption of pig iron, hence, when the proportion of sulphuric acid to copper is higher, the liquors are made to flow faster by passing them to lower vats in the series where the gradient is steeper. Another reason is that the tendency for basic sulphates and other impurities to precipitate increases as the quantity of copper falls and the free acid rises. To take advantage of these mechanical and chemical details and obtain maximum extraction at minimum cost, the analysis of the liquors must be known from start to finish.

The precipitant at Rio Tinto and Tharsis is pig iron, the pigs being laid in the vats like chequer work, four pigs deep. The great objection to using pig iron is that when the surface becomes coated with copper, the action goes on slowly. The shell of copper protects the iron. The chequer-work arrangement of the pigs exposes a large surface of iron to the liquors, but far greater exposure obtains when scrap iron is used.

Referring once again to the equation

$$CuSO_4 + Fe = FeSO_4 + Cu,$$

and interposing the atomic weights of the elements, we find that (in chemical exchange) 56 parts by weight of iron are equivalent to 63 parts by weight of copper. This is the theoretical exchange. In practice many other inter-actions occur, depending on the analysis of the liquor.

The first reaction that occurs in the liquor running over metallic iron is the reduction of the ferric sulphate to the ferrous state. It is therefore advisable to preclude every chance of oxidation. The second reaction is the precipitation of the metallic copper, brought about by simple galvanic action. The iron becomes cased with copper and thus the iron and copper in the acid liquor constitute a galvanic couple with considerable difference of potential. It is due to electrolytic action that all metals electro-negative to iron are precipitated.

While the liquor is fairly strong in copper, the copper is mostly precipitated in a coherent form, but in the later stages (as the liquor becomes impoverished) it is precipitated in a powdery state and with it a larger precipitation of impurities. The consumption of pig iron to the precipitation of the copper varies inversely as the quantity of copper in the liquor.

The temperature of the solution is also a factor in precipitation. During the summer months precipitation goes on far more rapidly than in winter. A temperature of 100° F gives excellent results.

The exceptionally good work performed at Rio Tinto and Tharsis is proved by the fact that only 1.4 units of pig iron containing 92% iron are consumed per unit of copper obtained. Sixty per cent of the copper in the liquors is precipitated within the first 760 metres of the vats. Over 70% of the precipitate contains more than 94% copper.

The following points have been established by this summary of Rio Tinto practice:

1. The complete analysis of the solutions both before and after treatment is essential to prevent undue consumption of iron.

2. Free acid is to be eliminated as much as possible.

3. Mechanical contrivances will, in a measure, overcome these chemical difficulties. The inclination of vats and consequent velocity of current should be in inverse ratio to the amount of copper present; the less the copper and the greater the free acid and ferric iron, the greater the inclination necessary.

4. As large a surface of iron should be exposed to the liquors as is possible.

5. Aeration of the liquor by tumbling through the air is objectionable, since it is an oxidizing reaction and so increases the consumption of iron.

6. In the course of the flow of the liquor through the vats there is a place where the cost of iron exceeds that of the value of the copper obtained.

7. The warmer the liquors, within certain limits, the faster is the precipitation of the copper.

At Butte, previous to the removal of the reduction works to Helena and Anaconda, the smelters and concentrators of the producing mines were built along Silver Bow creek. Enormous masses of tailing and slag carry-

ing appreciable quantities of copper, both as oxide and sulphide, have been dumped here and allowed to accumulate until the original course of the stream has been obliterated. The copper-charged waters pumped from the mines all ultimately find their way into the creek.

A reputable engineer, who has worked for years in the Butte district, claims that the flat through which Silver Bow creek runs will average nearly 2% copper for a depth of several feet. There are thousands upon thousands of tons of this material offering a wide field for close figuring and careful study in the extraction of copper. If a few experiments will determine what arrangements give the best results, why not investigate it? The water of Silver Bow creek is very acid and contains (from its contamination with mine waters) salts of copper and iron. I question whether a complete analysis has ever been made of this water. This same engineer tells me that a few samples of the water tested showed from 0.02 to 0.074% copper. No determination of the ferrous and ferric iron and free acid was made. I doubt not that it is an ideal solvent for the copper in the tailing provided it can get to it. I would suggest that periodically the surface of the tailing be turned over with a plough or that numerous small pits be dug from time to time in the flat—anything to insure greater contact action and more rapid percolation. A rough dam might advantageously be built across the lower end of the narrow channel; this would stay the underground flow and catch the richer liquors near bedrock. Anything that would cause more intimate contact with the interior of the pile of tailing is a move in the right direction. The idea of ponds on the tailing-bed is good, but I doubt very much whether, if actual tests were made, the percolation factor would be appreciated.

Precipitation Plant at Butte.

It is estimated that the Parrott precipitation plant alone cleans up about $25,000 per month, while extracting but a small percentage in the solution. The consumption of scrap iron is figured at four units of iron per unit of copper obtained. I noticed while visiting the several primitive plants in Butte that it is a common practice to elevate the solution to the top of a tower and allow it to tumble through a series of racks on which the scrap iron is placed. I cannot see the object of such a method of procedure unless it be that the fall of the water breaks the thin film of precipitated copper and exposes fresh surfaces of iron to the liquor. I think it would be better to use wider and deeper boxes, lessening the velocity of flow and arranging the scrap iron so that a larger surface area is exposed to a given quantity of liquor. As I have said before, little or no attention is given to the extraction obtained. By using more vats, and regulating the flow through them, I am convinced that much more remunerative results would be possible. Both the entering and effluent waters should be tested at least twice a day for free acid, ferrous and ferric iron, and copper sulphate. The ferric sulphate liquor returned from the precipitation vats will slowly dissolve more copper from the tailing and, being re-charged, is ready for re-precipitation.

There is a great field for economic work along these lines. I do not advocate such elaborate schemes as are practised in Spain, but much can be learned by a small expenditure of money to increase the extraction and reduce the cost.

HEALTHY COMPETITION.—While unquestionably dangers can be foreseen as arising out of these great industrial aggregations—not only of capital but of industrial energy—dangers technical, social, and political—there are also great possibilities of good. One of the benefits may justly be claimed to reside in the large funds that are thus rendered available for technical research, from which the public derives benefit indirectly, even if the results are not published. But if we could banish secrecy; if every industrial establishment of any magnitude, which is in its own interest carrying on technical research, should encourage its technical staff to confer freely with the members of every other technical staff, would not the sciences and arts progress far more rapidly than if one huge organization controlled a given industry? All our principal metallurgical and chemical concerns have laboratories, and carry on investigations and make experiments, generally on a large working scale; and surely the advancement of technological science can be better attained in a number of such laboratories than if there were fewer or in only one. There is keener competition of wits when many are working independently. The friction of honest rivalry is a force not to be despised. The stimulus of ambition is sure to be stronger in smaller than in large consolidated workshops. The air in such laboratories is freer and purer than when men are working in the stifling atmosphere of secrecy. I believe that such a consolidation of mind and high impulses would carry us further and faster along the road of human progress than all the money that all the trusts could appropriate for the advancement of technical knowledge. —James Douglas.

BABBITT METAL, as originally manufactured, contained tin, copper, and antimony. The composition now sold under this name has lead as the basis, and a combination of lead and antimony makes a good anti-friction metal. Some brands of babbitt metal are simply the refuse from type-foundries or smelting works. In pouring, the metal should be just hot enough to char a dry pine stick, and a combination of asbestos-fibre and a heavy oil, made into a stiffly-plastic mass, makes a good material for the dams. It is not a good plan to use the steel shaft in casting the bearing, as the hot metal may spring it. A wooden mandrel is better.

The Smelter of the Mammoth Copper Mining Company, at Kennett, California.

Written for the MINING AND SCIENTIFIC PRESS
By DONALD F. CAMPBELL.

The site of the Mammoth Copper Mining Co.'s works near Kennett, on the Sacramento river, is naturally well adapted for the purpose, for the Mammoth mine, supplying sulphide ores, is within easy reach, abundant limestone occurs in the immediate vicinity, and quartz is available from the Quartz Hill and Old Diggings districts. The Mammoth smelter is owned by the United States Smelting, Refining & Mining Co.; the Mammoth Copper Mining Co. being the operating title of the local organization, for the parent company owns mines and smelters in Nevada, Utah, Kansas, Indiana, New Jersey, Mexico, and Peru.

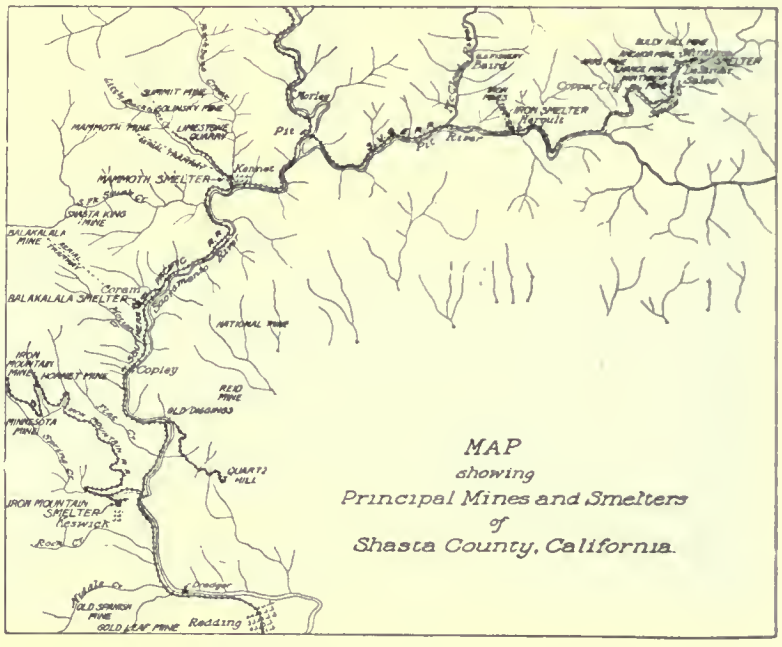
The development of this smelter is characteristic of the rapid growth of the copper mining industry in Shasta county. This enterprise was started about three years ago by the development of the mine, which is situated at a distance of 13,000 ft. from the smelter and at an elevation of 2,300 ft. above it. The ore is carried over an aerial tramway built by the Riblet Tramway Co. The tramway discharges into bins from which the ore is loaded into the charge-cars. Limestone is hauled to the smelter from Holt & Gregg's quarry, an electric road connecting this quarry with the smelter. Silicious ore and coke are brought from the outside, the railroad cars running over the top of the receiving-bins and discharging into them. The profile between the mine and the smelter is difficult and the sticky character of the ore also renders the existing method of transport unreliable and insufficient to meet the demands of the enlarged smelting works now being constructed. In consequence, the aerial system will soon be abandoned and a gravity incline used in conjunction with electric and steam railroads. The terminal machinery for the former will necessarily be massive, for the incline is 4,000 ft. long with a vertical drop of 1,700 ft. On this slope, which has a varying grade, two standard-gauge cars of nearly 20 tons capacity will be operated, the brake energy being partly absorbed by driving a compressor.

The Mammoth mine, which supplies the sulphide ores, is one of a series of masses irregularly distributed in a succession of rhyolite flows of pre-Devonian age along the west side of the Sacramento river. No proof is established that these orebodies are confined to any distinct lava and the various flows have not been clearly differentiated. Ore deposition has occurred by the total replacement of blocks of rhyolite bounded by fissures and shear-zones. Within these blocks the orebodies frequently show but little trace of the original rock, although in some cases the quartz phenocrysts can be distinguished.

At the Mammoth mine the ore is a massive pyrite containing from 3 to 12% of copper and carrying a uniform quantity of precious metals to the value of $1.50 to $3 per ton, a factor which materially adds to the prosperity of this enterprise during the vagaries of the copper market.

Many of the orebodies of Shasta county assume enormous proportions and are remarkable for their uniformity of character and comparatively shallow depth. The Mammoth ranks among the large copper mines that have been developed in the United States during the last decade, and the orebodies of the district have added notably to the known copper resources of the world, being surpassed only by the enormous low-grade deposits of Bingham and Ely and, possibly, the rich lodes in course of development in the Katanga district of the Tanganyka Concessions in central Africa. The value of the ore blocked out at the Mammoth was recently reported to exceed $15,000,000, but this must now be modified in view of the lower prices for the metal.

Diamond-drills have played an important part in the development of the mine and have met with success. They find application especially in blocking out orebodies when they are partially opened up, because the sulphides can be drilled more cheaply than the adjoining country rock. The latter is often highly silicified and in such a case the cost of drilling is almost prohibitive. Vertical holes driven down through the gossan ascertain whether it covers valuable sulphide deposits, for many such outcrops occur, beneath which the oxidation has been so complete that nothing of value is left, while other masses, especially of low-grade ore, being protected by a layer of rhyolite, have little or no outcrop. The cost of drilling in these rocks may vary from $1.75 to $4 per foot, and where time is an important object, this method of prospecting, being nearly four times as fast as mining, is satisfactory.



At the Mammoth smelter, from 300 to 350 tons of quartz is required per day; the company, finding the local supply of custom silicious ore altogether insufficient to meet this demand, has recently built a narrow-gauge road to the Quartz Hill mine, which has been leased for a long period. This deposit consists of a series of low-grade lenses of quartz carrying from $1 to $6 in gold, and about 93% silica, the latter being purer than the majority of local ores.

Regular shipments are also made from other adjacent mines.

As a result of numerous experiments and gradual development, the smelting of these ores is now economically accomplished. At first, the ore was all roasted, then pyrite smelting was successfully applied and developed to the extreme, until the consumption of coke was reduced to a fraction of 1%. The economic limit was exceeded, and at the present the coke in the charge varies from 3 to 4 per cent.

General View of the Mammoth Plant of the United States Smelting, Refining & Mining Co., at Kennett, California.

Interior of the Mammoth Smelter. Settler and Matte-Conveyor.

The plant is equipped throughout with the most modern machinery and a splendid system of store-houses and workshops. One building, 414 by 42 ft., contains electric, boiler, machine, and blacksmith shops, and at the end is the round-house, for the switch engines and a repair-shop for the mine railroad, the entire building being served by a 5-ton traveling crane and a complete hardware-store in the upper story of the building. Motive power is supplied by the Northern California Power Co.'s plants in the Sierra Nevada and about 3,000 hp. is used for blowing engines, compressors, and transportation.

The present plant has three blast-furnaces, each 42 by 180 in., with brick tops. The flow of matte is continuous from settlers, 6 ft. 9 in. outside diameter, into pan-conveyors which discharge into barrows. These barrows are wheeled on a platform to scales where the matte is weighed and then loaded into cars for shipment to the converter-plant in Utah. The cooling of the matte, while carried by the conveyor, is not sufficient to eliminate danger of putting the car on fire if loaded directly and for that reason the matte is dumped and cooled with a spray of water before being loaded into the cars.

The slag discharges from the settler into a swivel-pot from which it overflows into the slag-pot. The swivel-pot collects some of the matte that is carried over by the slag. It is found, however, that the amount of matte thus collected is very small. The settling in the receivers appears complete in spite of their small size. The slag is then hauled by electric locomotives to the dump. The track and the dump are situated on a level 8 ft. below the tapping-floor. This arrangement is convenient, as there is no interference of the slag-trains with the smelting operations.

The dust-flue is of brick, 200 ft. long and with an area of 156 sq. ft. It has hopper-bottoms through which the dust is drawn into cars running on tracks underneath. These cars are wheeled to an elevator and raised to a bin from which the dust is fed on a belt-conveyor discharging into the briquetting machinery. The stack is self-sustaining and of steel 12 ft. diam. and 150 ft. high above the base. Between the dust-flue and the stack there is a dust-chamber 60 ft. long and 456 sq. ft in area.

The power-plant contains three Connersville blowers of 124 cu. ft. capacity per revolution and having a speed of 132 r.p.m. These blowers are driven by three 200 hp. 2,000-volt 3-phase induction-motors made by the Westinghouse compauy. Two of these motors run at constant speed and the third is a variable-speed motor. A 100-hp. motor-generator set furnishes direct current for the locomotives.

Hitherto a 20 to 30% matte has been the product of the smelter at Kennett, this being shipped to Utah to supply the demand for the iron that is mixed with the silicious ores of Bingham. Of the three blast-furnaces at present in service, one has a steel water-jacketed top which is giving excellent results. So satisfactory has this improvement been, in preventing heavy incrustation and consequent freezing, that it will soon be adopted on all the furnaces. A light crust is constantly forming on the upper part of the furnace, but this soon falls off in scales; not only does it prevent the thick incrustation and subsequent freezing or low capacity that is usual with the brick tops, but this water-jacketed top also forms a scale of sufficient thickness to cause it to fall back into the furnace instead of being carried upward as flue-dust. This is an important development in blast-furnace construction.

The smelter plant is being much enlarged and it is expected that all the additions will be completed in January, 1908. Two blast-furnaces are being added; these are 50 by 180 in. with water-jacketed tops and settlers of 16 ft. diam. and an intermittent tap. The brick tops of the old furnaces will also be replaced with steel water-jacketed tops.

A building is being added for two converter stands and eight shells 96 by 150 in. The converter-building will be supplied wih two Morgan electric overhead cranes of 50-ft. span and with a main hoist of 50-ton capacity and two auxiliary hoists of 15 tons each, equipped with G. E. 440-volt induction-motors. In the power-house there will be added four Connersville blowers of the same size as the three original ones, but run by G. E. motors of 225 hp. A converter blowing engine of 10,000 cu. ft. capacity at 15 lb. per sq. in. will be driven by a 750-hp. 2,080-volt G. E. motor. In the extension of the converter building will be placed a re-lining plant with two pneumatic tapping machines of Ingersoll-Rand pattern, each supported by a hydraulic jib-crane of steel.

A dust-chamber, 200 ft. long and 407 sq. ft. in section, provided with hopper-bottoms, will be built of brick supported on a steel framework and concrete. A new self-supporting steel stack 18 ft. diam. and 200 ft. high has just been completed, into which the blast-furnace gases will be carried, while the old stack will serve the converters.

PRICE OF DIAMONDS.—This has been controlled for some years by a powerful combination of diamond merchants in London. Since the Boer war the value per carat has been steadily rising. The question of keeping up the price of diamonds, with a largely increased supply in prospect, is one that is frequently discussed, and leading authorities are agreed that at least twice the present annual supply could be absorbed without affecting the price per carat. But it is considered that only the better class of stones will always be in demand. The value per carat of the diamonds recovered from the principal producing mines, according to their latest reports, is: De Beers and Kimberley, $12.68; Wesselton, $8.86; Bullfontein, $8.38; Dutoitspan, $16.78; Jagersfontein, $13.86; and Premier, $5.64. Every diamond mine produces a certain amount of rubbish worth about $2.16 per carat; the percentage of these poor stones found determines the average value of the yield. At the Premier mine 75% of the total money value produced was represented by diamonds worth $12.60 per carat, and the balance of 25% was made up of diamonds worth $2.16 per carat. Similar variations in value occur in the stones found in all diamond mines. As showing the gradual increase in the average price realized per carat during the last 20 years, the following figures, taken from the report of the New Jagersfontein mine, may be of interest: 1887, $6.80; 1891, $8.92; 1895, $7.46; 1899, $8.28; 1903, $13; and 1905, $13.88. Since the issue of the report for 1905 the average price per carat has risen a further 5 per cent.

SWELLING GROUND is not confined to slates alone. Some igneous rocks swell upon exposure in mine workings. Experience has shown that the best way to keep drifts and other mine workings open in swelling ground is to timber heavily, spreading the legs of the sets widely at the bottom, and to 'lag open' in order that the swelling ground may find an easy passage through the spaces between the lagging. This method also admits of cutting away and removing the encroaching ground, thus keeping the main members of the set in their proper position. It has been found that almost every attempt to closely lag ground of this character has resulted in bending and breaking the lagging and in forcing the legs of the set out of place—often breaking or crushing the timbers. Large timbers offer little additional resistance over small ones in swelling ground.

The Mineral Resources of Sonora.

Written for the MINING AND SCIENTIFIC PRESS
By F. J. H. MERRILL.

Sonora covers an area of 77,000 square miles, all of which is highly mineralized. Deposits of gold, silver, and copper occur in remarkable abundance and, under modern management, many have developed great commercial importance, while hundreds remained unworked since their abandonment during the revolution against Spain from 1810 to 1821.

In silver production, during the Spanish occupation, it was surpassed by some of the interior States, and none of its mines have equalled the great producers of the central plateau, but from the beginning it has been, as it still is, the chief producer of gold and is also first in production of copper. Long before the Spaniards came, in 1521, the natives had developed primitive methods in mining and metallurgy, which gave them large quantities of precious metal, and copper or bronze implements were in use; but to what extent they conducted underground work is not known.

Sonora is pitted and honeycombed with abandoned shafts, open cuts, and underground workings which are now called *antiguas*, the term probably referring to all mining done before the revolt against Spain in 1810. In the clear atmosphere, on the treeless hills and mountains, the traveler sees everywhere the openings of the old workings that record the mining industry of the early days. In this climate of small rainfall and slow erosion, the gradual decay of vein-stones and impregnated rocks, wherever exposed, resulted in rich surface accumulations of precious metal, especially near the exposures of gold bearing veins and, in these detrital deposits or placers, the first miners reaped a rich and easy harvest. Later, under Spanish rule, the introduction of the *arrastre*, the use of quicksilver and various technical devices, gave the miner control of a larger field of action and new sources of profit.

Practically no machinery, however, was used in mining, and the notched log or 'chicken ladder' with the rawhide bucket on the back of the *peon* was the primitive substitute for modern hoisting and pumping machinery. So, also, the slow boring of shallow holes and the breaking down of the ore by the expansion of quicklime packed in the holes and moistened, made but a humble and inefficient substitute for the use of modern machine-drills and dynamite.

As a result of these conditions, work was limited in depth for lack of pumping machinery and in thoroughness by imperfect methods of extraction. The *arrastre* could be erected and worked without capital other than that needful to command the services of a cheap mule or burro and, since the slowness of the process was unimportant, and little or no value was assigned to the labor of man or beast, it was effective on free-milling gold ore, even of very low grade, but useless for the extraction of gold from sulphides. One therefore usually finds that an *antigua* mine has not been exhausted in depth unless the orebody was very shallow and that, in the old workings and below them, there often is rich ore unfit for the *arrastre* but available for modern metallurgy. Further, there may be waste dumps rich enough for treatment by modern methods, and at one time substantial returns were gained by a company which sent out a portable cyanide plant to treat the dumps of old *arrastre* tailing.

The Mexican native had, and still possesses, a keen instinct for the valuable ores in his native district and has probably left untouched no exposed deposit fit for treatment by his simple methods.

The ancient mine-workings or *antiguas* of Sonora are of much interest, for many of them have become richly productive in the hands of people with capital and up-to-date methods. Wherever the ancient miners worked extensively it may be inferred that they found ore profitable for treatment by their methods. That these old mines were rarely worked out is due to several reasons:

First, the lack of means for handling water, since many *antiguas* show rich ore when unwatered.

Second, the fact that the old miners knew nothing of the geology of ore deposits and did not appreciate that an orebody might be expected to pinch out or to be cut off by faults, and that a new orebody or the continuation of the first might be found by exploration. The old Mexican miner only followed the ore and knew nothing of systematic development.

Third, the early miners only sought for ores which could be worked in the *arrastre* or reduced in their simple *adobe* furnaces. Any gold ore, not free milling, or any silver ore from which the metals could not be recovered by their simple treatment, was useless.

Copper was of little interest to them and it is not known that any mine was actively worked for copper. The Aztecs, however, used some copper tools and a small quantity of this metal was used by the Spaniards for church bells.

Antigua mines differ very much in appearance from mines of the present day because the following of the ore was the only purpose in view, and little if any country rock was taken out. The underground workings are therefore of very variable dimensions and extremely irregular in direction. Where the roof needed support, this was more often supplied by pillars than by timbering, and in later years *gambusinos* and others have robbed the pillars and allowed the ground to cave. The *antiguas* are therefore generally full of water or caved in.

These remarks on *antigua* mines and mining necessarily apply to other parts of Mexico besides Sonora.

The geology of the State has been outlined elsewhere.[1] A summary of the subject may be given by saying that the following formations have been recognized: Crystalline terranes of gneiss and reddish granite are seen in Altar. The latter occurs also in Magdalena, and may or may not be equivalent to the granites of the southeastern districts. An extensive limestone formation, underlain by quartzite, occurs throughout the northern border of the State, apparently equivalent to that of Bisbee, Arizona, which ranges in age from Cambrian to Carboniferous. In central Alamos there is a limestone containing Paleozoic fossils, but its relation to the northern limestone is not yet known. A series of upper Triassic beds, carrying some coal, and graphite outcrops in Sahuaripa, Ures, Hermosillo, and Guaymas. Cretaceous limestone and shales are exposed in Ures and eastward, and lastly a great volcanic series of lava, tuff, plugs, dikes, and sills of quartz-porphyry, rhyolite, dacite, and andesite appears in all the districts, and contains many of the orebodies. Some of the copper deposits, however, are in limestone. Intrusive granites and diorites also occur at many points, but are not known to carry much ore.

Administratively, Sonora is divided into nine districts: Altar, Magdalena, Arizpe, Moctezuma, Ures, Hermosillo, Sahuaripa, Guaymas, and Alamos. These are similar in importance to our counties, but are better known to Americans as the bailiwicks of mineral agents with whom mining claims are filed for record, and of stamp agents through whom mining taxes are paid to the Secretaria de Hacienda in the City of Mexico.

While the mines are legally grouped in districts,

[1] *The Engineering and Mining Journal*, November 25, 1905.

geologically and topographically, they are grouped by the mountain masses and areas that carry the veins and orebodies. In general, mineralization is more conspicuous in the mountains than in the lowlands. This is partly due to the fact that the valleys, basins, and plains are more or less covered with debris from the mountains so that, in them, rock and vein outcrops are more commonly buried, while the mountain slopes, bare of soil and vegetation, expose the outcrops so that they can be seen from afar.

This condition is, however, also due to the fact that some of the basins and valleys have not been carved out of the mountains, but lie between volcanic peaks and ranges formed by the flow of lava through vents and fissures. From this it follows, that the geology of the valley or basin is often different from that of the adjacent mountains, and it frequently bears a different type of mineralization.

From the necessary dependance of the mining industry on transportation, the mines are commonly considered in relation to the valleys, which are the thoroughfares of commerce. .The chief gateways of Sonora from the north are three: Nogales by the Sonora railway, Naco by the Cananea railway, and Douglas by the Nacozari railway.

The first of these lines occupies a chain of valleys and basins, from the National boundary to Guaymas, and from this central depression extend tributary valleys and plains, which give access to the adjoining country east and west. Through the valley of the Cocospera at Imuris runs a stage-line to Cananea. Through the Magdalena valley from Santa Ana run stage routes to various parts of Altar.

From Hermosillo northeastward, highways radiate through the San Miguel and Sonora River valleys, and over the plains and hills to the east and southeast are reached portions of the Moctezuma, Ures, and Hermosillo districts, as well as Sahuaripa. From Ortiz a highway leads eastward to La Dura and other points beyond, while from Empalme the new Yaqui River railway starts out to open up the mines and coalfields along this well known stream. Alamos will also be reached in this way by January 1, 1908.

From Cananea, which is soon to be connected with Nogales by railway, the Sonora River valley opens southward; this is an important thoroughfare, crossed by the Sonora railway at Hermosillo, with rich farming lands along the stream, and mines in the hills on either side.

From Nacozari the valley of the Moctezuma flows southward to unite with the Yaqui, while over a short divide to the southeast the valley of the Bavispe leads, by its headwaters and tributaries, to the north and east and by the main stream south to the Yaqui. It may be noted here that none of the rivers of Sonora are navigable, except the Yaqui in its lower portion.

As mining is dependent on supplies of food for man and beast it is appropriate to say a word on agriculture. This industry is at present chiefly confined to the river bottoms, and their possibilities are very great. The ranches produce large quantities of wheat, beans, and corn, the staples of consumption, beans being the chief food of the Mexican laborer. Barley and alfalfa are extensively grown for hay, and a small amount of cotton is produced. Vegetable gardening is practiced on a small scale by Chinese, but no great variety of fruit raising has been attempted, though at Magdalena and Santa Ana are produced many peaches, quinces, and pomegranates, and oranges grow luxuriantly wherever planted, notably at Hermosillo and Ures.

The unequal distribution of rainfall throughout the year necessitates irrigation in the dry season, which extends with only occasional rains from October to June. The Mexican laborer has intuitive or inherited skill for such work, excavating *acéquias* or irrigating ditches, for long distances, without surveying instruments, and giving the necessary attention to the flow of water with efficient results and little apparent effort. On the river bottoms the expense is nominal, as a supply of water is near, while the irrigation of desert lands would involve questions of storage and cost, similar to those which arise in Arizona and California.

In consequence of the slight rainfall and the high evaporation, there are few permanent streams. The rains, limited mostly to the summer season, fall with great violence and cover the ground with water which does not at first form rills or brooks, but flows in sheet floods to lower levels. The accumulation of this flow gathers in *arroyos* or stream gulleys which, extending for miles as temporary conduits, ultimately discharge into some river which carries the drainage to the gulf. There are four such drainage systems in Sonora; the Magdalena, the Sonora, the Yaqui, and the Mayo.

Copper, gold, and silver are the chief metals of Sonora. Lead is of limited occurrence in association with silver and gold. Iron is known in Alamos, but the deposits are not yet developed. Antimony is mined in western Altar. Coal is of somewhat wide occurrence in the region of the Yaqui river, but is not yet mined for shipment. Graphite of good quality has been mined in Hermosillo, near Willard. Deposits of carbonate of soda and borax are also known in western Altar.

The following list of some of the better known mines of the State will give a general idea of its mining industry. Many of these have been visited by the writer and the data regarding others have been taken from sources believed to be accurate. No one, however, can enumerate the myriads of abandoned *antiguas* which, in the past, have yielded a rich harvest to the early miner, and which, in many cases, only need capital and intelligent development to make them again richly productive:

In this list the mines are discussed by districts according to the official classification.

ALTAR.

This district, which lies west of the Sonora railway, is the largest division of Sonora, and yields chiefly gold and copper. Its western part is a coastal plain of low altitude with stumps of eroded mountains projecting above the general surface. It is rich in gold-bearing veins and especially in placers, most of these being local accumulations of detrital material from the decay of veinstone and impregnated rock. The district was known for the great extent and richness of these deposits long before the Spanish occupation and, in its numerous gold-bearing veins some rich mines were developed, a few being still in operation. Altar is the most arid region of Sonora, and mining is greatly hampered by the scarcity of surface water; yet that obstacle is frequently overcome by pumping from wells or rivers. In the early working of the placers, millions of dollars were taken out without the aid of water, by the *batea*, or wooden gold pan, the natives being very expert in the use of this implement. The introduction of the dry washer from Hungary in 1851, has greatly facilitated the extraction of placer gold. These machines, of which various kinds have been devised, combine air-blast and agitation, the air from a bellows or rotary blower passing through the cloth bottom of an inclined table crossed by wooden riffles, down which the auriferous earth is made to travel by constant agitation. The blast carries away the dust and the gold is caught by the riffles. Dry methods can, of course, be pursued only in the dry season, when the

dirt is free from moisture, artificial drying being as yet not in use.

This district is richly mineralized, except, possibly, in a belt about 50 miles wide along the coast from Libertad southward. Within this area few mineral deposits have yet been found. It is, however, a desert without surface water, and this important article must be carried by the traveler, both for himself and for his horses or mules. It is possible that, when more wells have been established, and mere existence becomes less of a problem for the prospector, many good orebodies may be found in this coastal plain.

Altar, the capital of the district, with a population of 1,400, is about 50 miles west from Santa Ana. Nine miles farther west is La Cuchilla, where the Rey del Oro Mining Co. had a gold property with three Huntington mills. Near La Cienega, about 60 miles southwest of Santa Ana, are extensive placers. Over thousands of acres the ground is honeycombed with shafts and drifts where the pay-dirt was reached and brought to the surface for the separation of the gold by dry panning. This region was, however, worked over again by dry washers from 1884 to 1894, 10,000 people being employed. Part of the gold of this region is in a gravel, cemented with some degree of firmness and requiring mechanical treatment by stamps or otherwise to release the precious metal. Sometimes, however, this cement gravel can be broken up by wetting and exposiug to the sun and air. About seven miles northeast of La Cienega are the placers of La Yaqui, El Tiro, El Cajon, Cerro Colorado, Los Llanos, San Francisco, and La Sierrita, which have been worked intermittently for a long period.

In quartz mining also the region has been noted. The Tiro vein has been traced a long distance. At El Tiro, the north extremity, the Reina de Oro Mining Co. has sunk several shafts and is operating a 20-stamp mill. At El Cajon de Amarillas the Yerkes Gold Mining & Milling Co. has bodies of gold ore ready for stoping and a new 20-stamp mill. Cerro Colorado, between La Cienega and El Tiro has been worked for years, following rich streaks and stringers of gold ore, which was at first reduced in a small stamp-mill near La Cienega and later on by Huntington mills at the mine.

About 35 miles northwest of Magdalena is Tubutama, where the Juarez Mining Co. is developing a copper property. This company also owns the Juarez gold mine 30 miles northwest of Caborca. This is an *antigua* which was long worked as a placer by Papago Indians, who have found some large nuggets in the vicinity. In 1902 one was sold weighing 38.8 oz. The merchants of Sonora purchase placer gold from the Indians at about P26 per ounce. Its fineness usually ranges from 860 to 900.

A vein on the property was developed and worked in 1891 by a San Francisco company, which erected a 20-stamp mill with pan amalgamation. This process was not adapted to the work and a cyanide plant will be installed by the new management.

Thirty-six miles northwest of Caborca beyond the Juarez is the Palomas placer field. At La Calera, nine miles west of Caborca, the Arizona-Mexican Copper Co. of Phœnix is developing El Gran Proveedora de Cobre, a copper property on which development to the depth of 500 ft. has revealed extensive orebodies. Another copper mining company, the Ohio-Mexican, has also been operating near here with a 60-ton smelter.

On the Gulf coast near San Jorge Bay and at Quitovac, the Sierra Pinta Mining Co. has in operation two gold properties connected with the reduction works at San Jorge Bay by 13 miles of narrow-gauge railway. East of Sierra Pinta, at El Plomo and San Francisco, are important gold properties and some copper prospects are being developed. The Sombretillo is near the Arizona line. Near Cobota also are some copper prospects of good promise. An important area of new mines is in the vicinity of the Ranch of Las Animas, near the southeastern corner of the district and about 15 miles west of the railroad. Many promising prospects are being developed here.

This region was the chief source of the great supply of gold which during the Spanish occupation poured across the Sierra Madre to the viceregal court at the City of Mexico and thence to the royal treasury of Spain. Before that time, it supplied much of the gold that the Aztecs accumulated and which was wrung from them by the *conquistadores*.

In the southeast corner of Altar, on and near the ranches known as Las Animas and Las Rastras, is a group of mineral veins yielding lead, silver, gold, and copper. No large mines have yet been developed but active work is being prosecuted in a number of camps. Prominent among these are Las Animas, La Compañia, La Valedora, El Aguila de Oro, and Republica del Sur.

MAGDALENA.

East of Altar is the Magdalena district, containing a number of historic mines of the Spanish occupation. One of the most interesting of these is the Planchas de Plata, about 12 miles southwest of Nogales. The ore here is a quartz-porphyry conglomerate carrying horn silver.

About six miles north of Planchas are the Promontorio mines, owned by parties at Nogales. The ores are sulphides of lead and copper carrying gold and silver. Twenty-seven miles southeast of Nogales is the new Santa Cruz Copper camp, with veins of chalcopyrite, on which W. C. Greene and others have recently denounced a large number of claims.

West of Cibuta on the Sonora railway are the Guacomea mountains, in which some mining has been done. About 12 miles east of Quijano station and 30 miles southeast of Nogales in the Pinitos mountains, is the property of the former Hays Mining, Milling & Lumber Co., now in the hands of the Columbia Consolidated Mining Co., consisting of 50,000 acres of timber-land with veins of copper, gold, and silver. On the eastern slope of these mountains is the Buenaventura Mining Co. East of the Pinitos Mts., in the Cocospera valley, are the ruins of an old Mission church of that name, with vestiges of a large settlement and slag-dumps, which show that the place was once the site of large operations. On either side, in the Sierra de Pinitos or in the Sierra Azul to the east, are old mines whence came the ores reduced at the smelters. The Sierra Azul Mining Co. has developed a good orebody in one of these. At the mouth of the Cocospera river, where, by its junction with the Alisos river, it gives rise to the Magdalena, is Imuris, a small village built on a high terrace. Four miles west is the property of the Superior Bonanza Mining Co. of Calumet, Mich. This property has been partially developed and shows promising bodies of oxide and silicate ores carrying gold, silver, lead, and copper, as well as the mineral wulfenite, which is rare in this district.

Some six miles north of Imuris, on the mountain known as Cerro Blanco, is the gold mining property of the same name, long ago partially developed and recently under examination by British capital which will probably take it up for further development. From Imuris the Sonora railway follows the Magdalena valley past the city of that name, 50 miles from Nogales. With 3,500 inhabitants, it is the capital of the district and the centre of an active trade with rapidly developing mining regions and a rich agricultural district along the river.

Thirty miles southeast of Magdalena the Dolores and Santo Domingo rivers unite to form the San Miguel. Above the junction, in the Santo Domingo canyon, is the placer goldfield bearing the name of the river, and farther up the stream is a similar deposit at La Brisca. Both of these are held by the Greene Consolidated Gold Co. They were formed by the erosion of gold-bearing veins in the ranges surrounding the river valley, known as the Caliche, Sierra Azul, and Santa Rosalia mountains, forming a natural basin drained by the river. In this region are also several *antiguas*, in particular the Cerro Prieto, Caliche, Rey del Oro, Klondyke, and Tucabe. The Cerro Prieto property is extensive, with a large body of low-grade gold ore, opened by a series of adits connected by winzes through which the ore is brought down from the upper levels to the lowest, and thence transported to the mill. The latter is large, and the first unit of 120 stamps has lately been installed. The mine and mill are operated by electric power from a new plant at Magdalena. Water for the mine is pumped three miles from the Santo Domingo river. This property is operated by the Black Mountain Mining Co., of Chicago.

Seven miles northeast of Cerro Prieto is the Providencia gold property. Beyond this is the Caliche, a low-grade gold proposition bonded to the Greene Consolidated Gold Co. Beyond the Santo Domingo river eastward, 12 to 15 miles from Cerro Prieto, are the Tucabe and Klondyke mines. The Tucabe operates a 15-stamp mill. Near the Klondyke is the Rey del Oro, an *antigua* with extensive workings.

On the San Miguel river, at the junction of the two streams which unite to form it, is Cucurpe, the site of an older settlement of some importance during the Spanish occupation. Ten miles west of Cucurpe is La Higuera, an old camp with ruins of many *arrastres*. The property is operated by the Brady-Levin Co., of Nogales. Southward along the San Miguel valley there are mineral veins in the mountains on either side and westward toward the railway are the Santa Barbara, Soledad, Otate, and other camps with many *antiguas*.

About 15 miles west of Llano, on the edge of the Altar district, is the mountain country of the Rastras Ranch with many mineral veins. Near Llano station is the San Francisco mine, a gold property with a 10-stamp mill and a cyanide plant for treating the tailing, which was in operation for many years but is at present idle. Las Rieles is another property in the neighborhood. West of Llano three miles is a dry placer. The Libertad is a new gold mine operated by the Llano Gold Co. three miles northwest of Llano, while 10 miles southeast is the Caracahui range, in which are the Llano Copper Co. and the Sonora Copper Co., both actively engaged in development work. About 30 miles southeast of Llano is the Soledad mine, an *antigua* owned by W. C. Greene.

ARIZPE.

The Arizpe district adjoins Magdalena on the east and is drained by the Sonora river. About 50 miles southwest of Bisbee is the copper camp of Cananea, where the Greene Consolidated Copper Co. in seven years has developed one of the greatest copper properties in the world. The production of the district in 1906 was 18,108,640 lb. refined copper. Cananea supports a population of 23,000 and is the largest camp in Sonora. Ten years ago there were not 500 people in the region. Besides the Greene company a number of others have sprung up around it, there being in existence at present the Democrata Mining Co., of Cincinnati, the Indiana-Sonora, controlled by Phelps, Dodge & Co., the Cananea-Duluth, and the Cananea Central, which has recently been united with the Greene Consolidated.

Arizpe, the capital of the district, is on the Sonora river, about 75 miles south of the national boundary, and was a place of much prominence during the Spanish rule. It is now a town of 1,400 inhabitants, though once said to have contained 35,000, and shows the ruins of dwellings, churches, and other buildings, covering a large area. Vestiges of old furnaces and slag-dumps bear witness to former metallurgical operations. This city was in 1804 the seat of government of the Intendencia de Sonora, which included the provinces of Sonora and Sinaloa. About 1823 the seat of government was transferred further down the Sonora river to Ures, once also a city of wealth and commercial prosperity. Here, in turn, the changes in commercial conditions made it advisable to transfer the State capital to a more accessible point and it is now at Hermosillo. North from Arizpe and west from Bacoachi is the Picacho gold mine. In the vicinity of Bacoachi are extensive placers, and northward, in the Ajo mountains, are several new copper prospects, notably that of the Cananea Eastern Mining Co., about 20 miles east of Cananea. Fifteen miles west of Arizpe are the Santa Rosalia gold mines of ancient fame. Ten years ago these were re-opened by a California company, which afterwards sold to George Mitchell. The property is now idle.

Fifteen miles southeast of Arizpe, near Bavicanora, is the famous Las Chispas silver mine and near it the Carmen mine, which has recently been re-opened. Farther down the river, near Banamichi, is the Santa Elena mine, once operated by General Pesqueira. Later it passed into the hands of an English company, but it is now idle. Eight miles below Banamichi is Huepac, where a Milwaukee company is operating a small reduction plant. There are myriads of old mines and new prospects in the Arizpe district, but few companies are as yet operating there.

MOCTEZUMA.

East of the Arizpe district is that of Moctezuma, which is bounded on the east by Chihuahua. At Nacozari is a great copper property connected by a branch line with the El Paso & Southwestern Railway at Douglas, 80 miles distant. It is under the control of Phelps, Dodge & Co., who operate the Copper Queen at Bisbee, the Indiana-Sonora group at Cananea, and the mines at Globe and Morenci. The concentrate from Nacozari is shipped to the smelter at Douglas.

In the Huacal region, east of Nacozari, are many famous *antigua* mines, such as the Huacal, Doña Maria, Churunibabi, and many more. Northeast of Nacozari, 60 miles beyond the Bavispe river, is the Pilares de Teras region where are the Cinco de Mayo and Roy mines. Not far away is El Tigre, a recent discovery, rich in gold and silver. Two or three miles farther, and nearer Pilares de Teras, are the San Juan mines. In the southern part of the district, at Lampazos, there is a silver property with a long record of rich production. The ore is treated by lixiviation. In the vicinity are many *antiguas*. Copper mines of some promise are found at Transvaal and Promontorio.

URES.

The Ures district is one of the richest in the State and the list of its mines begins at the north, in the valley of the San Miguel river where the latter leaves the Magdalena district. Eastward from the town of Tuape are the extensive copper properties of the Richfield Mining Co., upon which development work has been actively conducted. There are other old mines and prospects in this vicinity. Westward toward the railway is the

Querobabi region in which are a number of promising gold properties. Farther down the San Miguel valley, west of Opodepe and east of Poza station, is the San Ricardo, a gold mine with a record of rich production going back to ancient days. Twelve years ago it was operated by an American company, which erected a 20-stamp mill and shipped gold bullion. Detected in smuggling gold out of the country, the property was confiscated by the Mexican Government. The mill fell into ruin and later the claims were taken up again and sold to a Canton (Ohio) company, which has begun development and erected a mill.

Several miles west of San Ricardo is the Mina El Oro, operating a Huntington mill and shipping bullion. The Santa Gertrudis is another good property near-by. In the same vicinity is the Amarillas, a silver property with a good record. Six miles south of the Amarillas is the Socorro, which also has a good record of production. In the same region are the Nopalera, Tortuga, and others. From San Ricardo and El Oro on the north to Nopalera and Socorro on the south, an area about 6 miles by 16, the country is cut by numerous veins that show gold and silver in the croppings. A few leagues farther down the river from Opodepe is Rayon, the centre of another important mineral belt in which is the copper property of the Palo Alto Mining Co. Below Rayon is the San Francisco gold mine. Southwest from Rayon about seven miles is the Copete district, where the Copete Mining Co. has large holdings and a smelting plant of 250 tons capacity. Adjoining the Copete is the Sultana property of the Giroux Consolidated Mining Co., one of the important mines of Sonora. A shaft is down 1,050 ft. in rich oxidized ore carrying copper, lead, gold, and silver. Within three years, large shipments of rich ore have been made to the smelter at El Paso. South of the Sultana is the El Colorado property of C. S. Mills and associates which is said to contain large bodies of low-grade gold ore. North of the Sultana and Copete properties is that of the Beleu Mining Co. with headquarters in Chicago. This Copete district is characterized by strong evidences of extensive mineralization and there is every reason to expect the development of some extensive orebodies. The camp is supplied with water by a pumping station at Rayon.

In the valley of the Sonora river, about 25 miles southeast of Copete and 12 miles southwest of Ures, is the Gavilan region, prominent in ancient days. Here the Ures Consolidated and the Vega Mining companies are operating, the former with a 10-stamp mill. A few miles farther up the river the Coches Mining Co. is developing a gold property.

The city of Ures, the seat of government in this district, is 56 miles from Hermosillo and has about 2,000 people. To the southeast, toward the Matape river, are the Chipiona and Colorado-Ures camps, a few miles northwest of the town of Matape. Ten or twelve miles south are the Marquesa and Quincy mines. Fifty miles southeast of Ures near the edge of the district is the Llano-Colorado region, famous for its placer diggings more than a century ago. A few miles west are the Realito mines where extensive old workings and the traces of many *arrastres* tell of active mining in former days. From the Los Angeles mine silver ores have recently been shipped.

Twenty miles northeast of Matape and about 60 miles from Minas Prietas is Suaqui de Batuc, near the confluence of the Moctezuma and Yaqui rivers. The former comes from near the Arizona line, nearly 200 miles north, and the Yaqui or Aros flows from Chihuahua on the east, turning at its junction with the Moctezuma and flowing south. Along both rivers are rich mineral regions. Southeast of Suaqui de Batuc in the Sahuaripa district, are the Santo Nino mines once owned by the Yaqui Copper Co. In the vicinity of Suaqui de Batuc are also Todos Santos, El Cajon, Zaragoza, Estrella, and other properties, several in course of development. Near Batuc, about two leagues above Suaqui, is the Lista Blanca mountain, where a network of silver veins ramifies to considerable depth and has been worked almost continuously for two centuries. There are also deposits of copper and quicksilver in the same mountain. The Tonichi copper property, owned by the Trimetallic Mining Co., is about 10 miles east of the Yaqui river, and coutains a vein of copper ore with gold and silver.

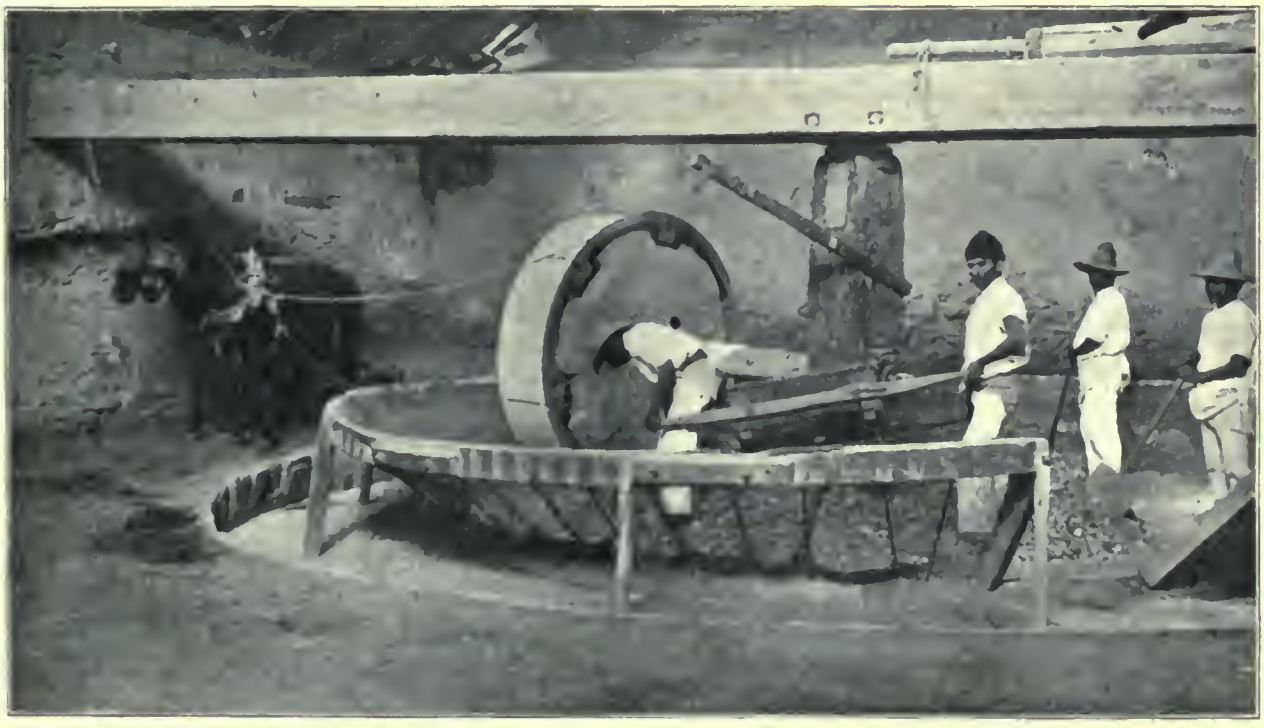
HERMOSILLO.

South of the Ures district is that of Hermosillo, in which is the important mining camp of Minas Prietas, about 35 miles southeast of the city of Hermosillo and 12 miles from the Sonora railway at Torres, with which it is connected by a narrow-gauge line. Two large properties are operated here, the Creston-Colorada and the Grand Central, and until the development of Cananea this was the largest camp in Sonora. The region was one of *antiguas*, some of the mines, including the Colorada, having been worked more than a century and a half ago by Jesuit missionaries. Depredations by Indians are said to have compelled their abandonment. About the beginning of the nineteenth century the Prietas and other properties were worked with good results by miners who had been attracted by reports of former success. After a second abandonment, on account of water, they were idle for many years. About 1860 several of the old mines, including the Creston and Prietas, were re-located by Ricardo Johnston, a man prominent in the mining history of Sonora. The two properties mentioned were pumped out and worked with profit for a number of years. The Prietas was then sold to an American company, which built a 40-stamp mill and operated successfully until operations were stopped by a fire in the shaft. In 1886 these holdings and others were taken over by the Creston-Colorada company, of Cleveland, Ohio. Subsequently the control of this corporation passed to a syndicate headed by John W. Gates. This company owns the Prietas, Fortuna, Creston, Colorada, Don Ignacio, and other properties extending a mile or more along the wider vein. The Creston, Fortuna, and Prietas are at Minas Prietas and the Colorada and Don Ignacio at La Colorada, a part of the same municipality about a mile away. Here is the mill of 30 stamps, six Huntington mills, nine amalgamating pans, and 16 Frue vanners, with a daily capacity of 200 tons. The tailing is treated by cyanidiug. The mill is connected by a wire-rope tramway with the hoist at the Creston shaft 1,100 ft. deep, through which is raised the ore from the Fortuna and Creston mines. About 1890 rich orebodies were developed in the Grand Central, Amarillas, and other properties on a vein parallel to that in which all former successful operations had been conducted and another great enterprise was launched. In a part of the camp known as La Primavera, adjacent to La Colorada, are the Grand Central and Amarillas mines, owned by the Grand Central Co. and leased to the Charles Butters Co. The ore from these mines goes through the stamps and Huntington mills, and from the latter to the large cyanide plant, which employs the Butters electrolytic process of precipitation and has a daily capacity of 400 tons. The ore is said to run from $5 to $7 per ton.

In the spring of 1907 the Butters Co. took over the control of the Creston-Colorada properties, so that the whole camp is now under one management. Water for the mines and mills is supplied from the Matape river, 20 miles away, by a pumping plant at San José de Pimas.

There are other properties in the Prietas district that promise well and may, with development, become productive. Between Prietas and Hermosillo are the Dewey, Mina Grande, and several other mines. Twelve miles north of Minas Prietas is the Zubiate district, where are several silver mines with good records of production in former days. North of Zubiate and east of Hermosillo are the Tortuga, Constitution and Italia, Last Chance, Santa Rosa, and Las Cruces. About 12 miles west of Torres are the mines of the Tarrasca Mining Co. This is another *antigua* camp. Five miles east, at Aguage, are vestiges of old *arrastres* and many tailing piles, showing that much ore was treated there in the old days.

From Minas Prietas eastward, roads lead to all points along the Yaqui river, about 100 miles away. Beyond this, in the Sahuaripa and Alamos districts, lies one of the most important mineral regions of Sonora, which in old days was one of the best in New Spain. West of the river, also, in the Hermosillo and Ures districts, are extensive mining regions with historic records. Among



Grinding Ore in a Chilean Mill, in Mexico.

these are the camps at San Javier, La Barranca, Los Bronces, San Antonio de la Huerta, Las Goteras, Cerro Colorado, San Juan Grande, and Soyopa. At San Javier the Gold Coin Mining Co. has a 30-ton copper smelter. This company also owns the Santa Rosa, a well-known *antigua*. At the same place the Wyman Mining Co., operating the Animas mine, has erected a 50-ton concentrating plant. The Verde Grande is a copper property near San Javier. At Toledo, on the west bank of the Yaqui river, the Yaqui Smelting & Refining Co., of Toledo, Ohio, has established a custom smelter, having a 100-ton lead stack and also a copper furnace. Near Suaqui Grande, on the Tecoripa river, the Chicago & Sonora Gold Placer Mining Co. a few years ago installed a gold dredge and operated with some success. This placer field is about 30 miles long, extending along the Tecoripa river from Suaqui Grande to its junction with the Yaqui at at Cumuripa. There is also a placer field along the Yaqui river, in which a dredge was operated by Milwaukee people. Northwest of Hermosillo about 40 miles are some copper properties, notably the Verde Grande, the Lluvia de Cobre, and El Mohin. The first of these has a 100-ton smelter. Near the Gulf coast in the Bacoachi region are other copper deposits now under development.

SAHUARIPA.

East of Ures and Hermosillo and south of Moctezuma, the Sahuaripa district was one of the great centres of metal production in early Spanish days. It contains the Trinidad, La Bufa, Mulatos, Cieneguita, Tayopa, Ostimuris, Tejada, and many other noted mines, which, according to the Spanish records, yielded a large output of metal during nearly two centuries.

A day's ride east of Tonichi lies the region of La Bufa and Trinidad. Within 20 miles are over 100 *antiguas* that have, in early days, been large producers and promise good returns with the intelligent use of capital. .

The work of the Bufa Mining, Milling & Smelting Co. illustrates the possibilities. Seven or eight years ago a few practical miners from Minas Prietas and La Dura took up the *antigua* known as La Bufa. They sunk a new shaft and at a depth of 300 ft. reached the orebodies formerly worked at higher levels, and, continuing to a depth of 600 ft., they opened a body of high-grade ore, which stood the cost of transportation 150 miles on mule-back to Torres and thence by rail to El Paso. The lower-grade ores were concentrated and also shipped. A 35-ton smelter was then erected and matte made on the ground.

About 10 miles distant are the Trinidad mines, once famous as silver producers. The parties who opened La Bufa have purchased the Trinidad and are pushing development work with promising results.

A day's ride northeast of Trinidad are the Mulatos gold mines owned by the Greene Gold-Silver Co. North of Trinidad are the properties of the Cieneguita Copper Co., including the Chipiona-Cieneguita, Ostimuris, and Tayopa. These are all *antiguas* with high records of production in gold and silver. Two 10-ton reverberatory furnaces are in operation. Near Trinidad are outcrops of a Triassic coalfield.

ALAMOS.

Adjoining Sahuaripa on the south is Alamos, noted in

the history of New Spain for its production of silver. At the city of Alamos was a branch of the Public Treasury, and from it were sent out the *conductas* of hundreds of mules laden with gold and silver ingots that traversed the Sierra Madre to the City of Mexico, whence the treasure was sent to Spain. West of Alamos city is the Quintera mine, once a rich producer, and the source of great wealth for the Almada family. The property still continues in operation under a French syndicate, and is worked to a depth of 1,500 ft. An extensive iron deposit occurs about 50 miles northwest of Alamos, near the village of Cedros. At Baucari and Trigo are gold quartz mines. At El Cerrito are placers, and at Baroyeca and Piedras Verdes are deposits of copper ore.

In the extreme north of the district is La Dura, about 80 miles from Ortiz on the Sonora railway. Here are extensive deposits of copper and silver. At Batamote, 15 miles south of La Dura, the Ruby Gold & Copper Co. operates a copper mine, reducing the ores in a reverberatory furnace.

GUAYMAS.

Southwest of Sahuaripa is the Guaymas district, through which passes the road from Ortiz to La Dura. There is considerable mining here and many rich deposits are known, but the Yaqui Indian trouble has retarded development. At San Marcial are extensive coal measures of Triassic age. The field extends northward into the Hermosillo district, where parts of the deposit, altered by volcanic action, have been mined for graphite. In the Bacatete Mts., southeast of Guaymas, is the Bonancita region, with veins of auriferous quartz and numerous placers. At La Barranca, six miles from Toledo, is an extensive deposit of anthracite and natural coke, controlled by the Southern Pacific Railroad Company.

GENERAL.

Although its mineral wealth was known of old, Sonora was practically shut to the miner for nearly half a century after the close of the revolution against Spain. This was due to the depredations of the Apache Indians who, after the Mexican troops retired, ravished this Southwestern country. It has indeed been truly remarked that for a long time Sonora was under the Apache government rather than that of Mexico. After the purchase by the United States in 1853, under the Gadsden treaty, of the territory south of the Gila, southern Arizona was somewhat protected by soldiers till the beginning of the Civil war when, on the withdrawal of these troops, the savages overran many of the white settlements. The region remained subject to their depredations and largely closed to commerce till after the completion of the Southern Pacific railway. This greatly facilitated the transportation of troops, and the capture of Geronimo soon followed in 1884. From that time dates the opening of Sonora to the modern miner.

The production of copper in Arizona in 1906 reached 263,200,000 lb., that is, greater than that of Michigan, 83% of that of Montana, and 28% of the total product of the United States. The question arises, to what extent the supply may be increased from the region just over the border of Arizona?

In Sonora this metal is so frequent in occurrence that we may expect a rapid expansion of production beyond the present large output of the great mines of Cananea and Nacozari, which in 1906 reached the imposing figure of 61,000,000 lb. Other smaller camps produced an aggregate of about 1,000,000 lb. more, thus making a total of about 321,000,000 lb. copper for Arizona and Sonora, against 315,000,000 lb. for Montana.

The copper zone of Sonora is the southward continuation of that of Arizona, and extends over nearly the whole State. Deposits of this metal occur rather frequently in all the districts, except Guaymas.

As in Arizona, so in Sonora, the principal copper orebodies are in limestone or associated with it, and, in turn, are in close relation to masses or dikes of eruptive rock, which contains copper or has stimulated the flow of a copper-bearing medium.

While the presence of green stains of malachite and dioptase on quartz veinstone has led, in many places, to the expenditure of much time and money in the attempt to make copper mines, it seems established after many trials that no one has yet succeeded in developing a substantial copper mine on a quartz vein in Sonora. In some of the silver mines, tetrahedrite occurs in quartz and from this copper comes as a by-product with the silver, but the large copper producers are all, or near, lime-porphyry contacts.

Quartz veins in Sonora, as elsewhere, are not always productive of the precious metals. Many large quartz veins are quite barren, although deposits of commercial importance are often found in the country beside the vein. Further, many of the largest and most productive orebodies contain very little quartz. Most of the large veins carry copper, lead, gold, and silver. There are few mines of silver free from copper. Gold occurs in nearly all the copper ores, so that the copper mines are usually producers of gold. A notable exception is the Pilares mine at Nacozari. Gold also occurs to some extent free in quartz veins. These are chiefly in Altar. Iron pyrite and the copper sulphides carrying gold yield, by their decomposition, oxides, silicates, and carbonates which give up their gold to amalgamation in the *arrastre*.

The zone of oxidation in Sonora is generally, except on the steep mountain slopes, quite deep, and so few of the mines have been worked far into the zone of unaltered sulphides that it is too early to undertake a general discussion of the types of Sonora ore deposits.

It may, however, be stated as a result of the writer's observations that the predominant type is the impregnated shear-zone. This is a zone of shattered rock of greater or less width where fracture or faulting has occurred in a series of parallel fissures very close together. Through this fragmental material a metallizing solution has flowed, saturating the fragments to a variable extent with lead, silver, gold, copper, or other metal, but not carrying sufficient silica to form a district veinstone. Sometimes, local deposits of quartz are formed in the shear-zone, and these, when exposed at the surface, resemble true vein outcrops but do not continue far in length or depth, although there may be important bodies of ore beneath them. As might be expected, the metallizing solution appears to have usually taken a meandering course.

The orebodies are the record of a flow that has often divided in passing the less porous rock-masses, so that 'horses' are formed both along the vein and in its width. sometimes these 'horses' are not entirely barren but carry low-grade ore. The formation of large 'horses' along the shear-zone gives the effect of shoots or chimneys of ore that unite in depth. A peculiar condition, sometimes noticed, is the offsetting of the ore through the constriction of the zone of flow and its diversion in a lateral direction, to be succeeded after a distance by a widening again and the resumption of ore along the general course. The result of this is a deplacement similar to that which might result from the faulting of a fissure-vein. In the shear-zone, however, there is no marked fissure to guide the miner in determining geometrically the position of the displaced orebody. Exploration work alone will find it.

Progress in the Treatment of Gold Ore.

By Alfred James.

*It will not be possible for me to review the progress of gold ore treatment for this year in as detailed a manner as is usual, owing to these notes being written while traveling some thousands of miles away from my base.

Fine sliming and the treatment of slime is again the most interesting feature of the year's progress; even former exponents of coarse crushing are now converts to modern slime practice. From eastern Asia to West Australia and from South Africa to North America sliming methods are pre-eminent and have modified the other processes employed in the industry, such as crushing to tube-mills and the roasting of ores previously ground very fiuely.

Less has been heard this year of pans. Experiments in the Transvaal appear to have resulted in favor of tube-mills, and many more of them have been installed. With heavy stamps the Luipaards Vlei appears to have been able to crush 8.5 tons per head per diem, but in Rhodesia I am advised that 10 tons per head is being obtained in more thau one instance—crushing, however, to pans instead of tube-mills.

For the Rhodesian practice differs from that of the Rand. With their much smaller installations, pans are found to be more suitable and efficient, as being cheaper to install, forming more convenient units, and making less demand on power. In consequence, there are but few tube-mills operating in Rhodesia. The pans thus used are of the West Australian type.

But tube-mills have unquestionably been much improved. Linings now last longer and instead of having to stop a mill every three weeks or so for a week for a new lining, it is now possible to run for three to six months with a lining placed in position in from two to three days. Automatic linings such as those of the El Oro, where pebbles are supposed to fix themselves in rebates cast in iron liners, do not yet appear to have proved themselves entirely satisfactory, and changes have recently been made in the shape of the recesses, which have now their sides chamfered to each other. The use of quartz or other lode-matter to be crushed in place of imported pebbles has much increased, and this with the utilization of quartz and local chert or other hard rock in linings of the Barry or Brown type has materially reduced the cost of operating tube-mills. In Africa a mill is started with a charge of pebbles containing say up to 10% lode-matter, then in regular work it is found possible to reduce the daily feed of pebbles by 5%, adding rough lode stuff to balance until the daily feed contains only 10% of pebbles, the whole of the balance being the product of the mine.

It is in the treatment of the slime produced by tube-mills and other grinders that the progress of the year has been most manifest. The decantation process, which originated in Africa and which has so long survived there, has now had its day. Designed to treat material of low value at that time not amenable to any other method, it has resulted in profits being realized from material that otherwise must have run to waste. But the huge and expensive plant and low extractions must now give place to more automatic methods involving cheaper equipment and higher saving, and already such cyanide experts as J. R. Williams, W. A. Caldecott, E. J. May, and H. S. Denny have been looking into processes employed elsewhere, notably the Butters, Burt, Ridgway, and Merrill filtering devices.

In these notes of last year reference was made to the new Denny plants at the Meyer & Charlton and the New Goch. The Denny brothers severed their connection with these two mines shortly afterward, but in spite of their absence filter-pressing appears to be regarded as successful by the management, although much doubt has been expressed as to the wisdom of running cyanide solution through the mortar boxes. Mr. Geo. Albu has criticized this as making it difficult to obtain the assay-value of the mortar-box product, but I assume this point would not be regarded as serious if Mr. Albu were convinced he was obtaining a higher recovery of his gold. On the Rand, however, the Denny methods have not been followed. Rhodesia, on the contrary, having investigated the results, has had quite a small Dehne filter-press boom, plant after plant having been installed during the last year.

But undoubtedly filter-pressing, even with Dehne presses, must give way before the suction filters, of which so much has been heard in the past year. Cheap and efficient, the daily tonnage handled by vacuum-filters is increasing by leaps and bounds.

And of the various vacuum-filters on the market I must unhesitatingly refer first to the Ridgway. This differs from the filters of the basket type in being more rapid, working with thinner cakes, giving better washing, and emptying itself in more cleanly fashion (automatically) than the basket-filters. Working as it does with the whole cycle of operation complete in 60 seconds on normal slime, it will be seen that difficulties, such as keeping material on cloths during transit of frames or during emptying and filling of vats, are entirely avoided, while the washing of so thin a layer ¼ to ½-in. thick is much more rapid and complete than the washing of a cake of double or treble the thickness. The Ridgway is thus able to work with a much smaller area of filter-cloth for any given capacity.

During the year a 500-ton plant has been put into successful operation at the Great Boulder in West Australia, and I understand another plant of similar capacity has already been started. Plants of similar and smaller capacities have been erected (or are in course of erection) in Mexico, India, South Africa, and Eastern Asia. The official figures of the West Australian Chamber of Mines shows Ridgway to be working under expensive local conditions (such as purchased power, dear labor and supplies) for under 8 cents per ton treated; in Africa the costs should be little more than half this.

The Butters-Cassel filters has been installed widely in Mexico as well as in the Western States of America, not perhaps because it was the best vacuum type of filter—the recent published correspondence shows the pioneer Moore to be at least the equal, and probably the superior—but because it was pushed by a man of repute and of great energy who was recommending the best thing he could get hold of. But in the recent correspondence in the technical papers it appeared to me that the only parties writing in favor of the Butters-Cassel filter were those who were, or had formerly been, associated with Butters, whilst the Moore was recommended time and again by parties in no way associated with Moore, who had laid it down after investigation and who were apparently in no way connected—not even by paying royalties—to Moore or his associates. Certainly if the Moore process had been run with half the energy, experience, knowledge, and skill of the Butters, I cannot imagine the latter type of filter to be employed at all.

For it is obvious that the hoisting of a basket of frames is a much neater and better and quicker expedient than the pumping in and out of pulp and solution or wash, each successive charge being mixed with the residue of the previous charge, whether of pulp or of solution or of water, and it is within the knowledge of men

*See editorial paragraph.

experienced in slime filtration that the maintenance of a vacuum in a basket half immersed—or partially immersed for say four periods of ten minutes each during each cycle of operations—does not make for good results. The lower portion of the cake is being thickened by pulp deposit while the upper is cracking from the inrush of air, an unequal cake is formed, and the washing must be unequal, and there seems to be a great waste of water in discharging the cake after filtration. From the published correspondence it seems to be laid down without serious contradiction that the Moore is more accessible and open to inspection, and that it does more work for a plant of given cost or in a given time.

Further modifications of the basket-filter have appeared in the form of enclosed filters worked by pressure or vacuum, such as the Blaisdell, Burt, and Kelly. This form of filter is scarcely new, and when tried some years ago proved itself unhandy, liable to freeze or choke, difficult to wash thoroughly, and difficult to discharge—in a word, it seems to be an attempt to work in the dark. Of course, modifications of the standard immovable enclosed type are made; one runs the frame into a cylinder or runs the cylinder away from the frame; this makes the operation more accessible but so far does not appear to be as successful as the pioneer basket type.

Reverting, however, to filter presses, Merrill has at last got his big plant at work after three years' labor. It appears now to be working to nearly its full capacity—according to my recent information—and to be treating slime at a remarkably low cost. Advantage has been taken of every natural condition to make a successful working plant, and using static pressure to fill the presses and wash their charges, the Homestake costs are probably as low as any slime-treatment method yet put into practice. But my information is that with such a method the satisfactory treatment and hydraulic discharge of thick cakes in huge filter-presses is only possible with crystaline or granular slime and with a great waste of water. In a word, it appears that successful results may not be anticipated by the process on ordinary slime under ordinary economic conditions; the thorough washing of 4-in. cakes is feasible only with crystaline-granular or readily permeable slime.

The successful handling of slime has also directed attention to the solution of the gold contained therein. Last year I referred to the system of treatment based on feeding solution or wash-water at the bottom of a vat, the slime contents of which were in a state of gentle agitation, the idea being an overflow of clear solution containing the gold content of the charge. W. L. Holmes, of Mexico City (formerly in South Africa), brought this to my notice some years ago, but it did not appear to make headway. Bewick & Moreing were working it last year in West Australia, but evidently without commercial success, and this year Adair & Usher have been booming an apparently similar process in South Africa. Possibly some metallurgist at the Geldenhuis Deep, or elsewhere, may make something tangible out of the idea, but it looks as though the only result would be to call attention to the additional extraction obtained by the increased agitation of the pulp, and in this connection I have had reason to investigate the work of the Brown agitator.

This apparatus, introduced into New Zealand at the Komata Reefs, depends on the principle of the lessened specific gravity of a centre column into which air has been introduced at just such a pressure as will overcome the weight of the column of water at the point of introduction. There is no question of a jet of air circulating solution on the principle of the injector, but merely the physical lightening of the weight of a column by the displacement of a small proportion of the water by air. Brown uses long narrow vertical (cylindrical) vats, say 40 ft. by 10 ft., or 55 ft. by 15 ft., with a centre column of 1 in. diam. per 1 ft. of vat diameter. Into this central tube or column the air is introduced, and agitation is so effective as to lift stones at a minimum horsepower per ton. The power taken appears to be about 2½ hp. per 50 tons of charge, which is the slime content of a 40 by 10-ft. vat. By this method the advantage of the accelerating action of air agitation is obtained at a small cost.

The use of these vats has been offered to the Waihi—the manager of which speaks very highly of them—and Waihi Grand Junction in New Zealand, and a number have been installed in Mexico under the name of the 'Pachuca Agitator.'*

The progress of cyanide treatment for the silver-gold ores of Mexico has been one of the features of 1907. Chihuahua has been adopting cyanide with avidity, and Pachuca appears to be now coming into line. Of course, El Oro has done pioneer work, and Guanajuato has also been in the forefront. In almost every case the practice is similar. Tube-mill sliming and treatment of the slime at first by decantation, but now by filter. High extractions are claimed, but having regard to the natural refractoriness of silver sulphide ores—in some instances as at Chinacates associated with pyrite, chalcopyrite, galena, and blende—one is impressed by the necessity of having recourse to the most modern practice, whether for getting the silver and gold into solution or for recovering the solution from the pulp for precipitation of the precious metal.

There is but little new either in roasting or concentration of gold ores this year. Merton and Edwards still hold the field for roasting, and the many flotation processes applied to the zinc-lead ores at Broken Hill, such as the Potter, Delprat, De Bavay, Cattermole, and Elmore, do not yet appear to be successfully running at any gold mines known to me, although it is thought that the mechanical and metallurgical skill at the back of the Elmore process will bring it to the forefront during the coming year.

POTTER'S SULPHIDE TREATMENT.—Great satisfaction is expressed in Australia at the cessation of litigation in connection with the Potter process for the treatment of sulphide ores, the formal signing of the agreement between the litigant companies taking place at Melbourne recently. The details show that the Proprietary Company assigns to the Potter's Sulphide Ore Treatment Company, Limited, all the patents it holds in the name of F. M. Dickenson and G. D. Delprat, including those relating to the Delprat process. This is a formal conveyance of the rights, so that in future the Proprietary company will work under license from Potter's company. It will, however, pay no royalty, the consideration for the right to use the process untrammelled being £10,000. The Proprietary company will have full liberty to employ the process on all mines that it may absolutely own, but not to license anyone else to utilize it, the power to do that being vested completely in the Potter's company. No opposition will be offered by the Proprietary company to any amendment that the Potter's company may wish to make to its patents. Each side will pay its own costs in the litigation that has already taken place. This arrangement will prevent a further expenditure of many thousands of pounds in legal proceedings.

EXPERIMENTS prove that the addition of graphite to oil results in a lower frictional resistance of the surface lubricated than would be obtained by the use of oil alone.

*See MINING AND SCIENTIFIC PRESS of November 30, 1907.

Mexico. Progress in 1907.

Written for the MINING AND SCIENTIFIC PRESS
By C. A. BOHN.

Two months ago everything seemed to be upon a solid basis in Mexico; and all pointed toward continued prosperity in this Republic. Then all at once came the signs of financial trouble, money became tight, promising enterprises were set back, and working properties were closed, until only the best continued in operation, or a few large producers, which, by reason of their organization, must be kept running to meet fixed expenses. Under conditions such as these to review the year's work in Mexico is like writing the history of a devastating war.

The greatest collapse was at Cananea, in Sonora. The Cole-Ryan merger of the Cananea Central with the Greene Consolidated Copper Co., under the control of the former and with the name of the Greene-Cananea, was but little more than consummated at the beginning of 1907. L. D. Ricketts was placed in charge, and almost immediately a practical rebuilding of the entire plant was planned. At the mines the caving system had already been introduced, so that alterations for further economy had to be made elsewhere. Plans were drawn and work started to replace the two 2400-ton concentrating plants at the Cananea Central and the Greene Consolidated by one central plant with 10,000 capacity, wherein by gravity and every other means economy was sought, and several units were completed. At the smelting plant new furnaces each of 450 tons capacity were being erected to take the place of the old, and six of the eight furnaces have been completed. Now practically all this work has been stopped and of the 4000 men formerly employed only a few hundred remain. Of the other work at Cananea, the Phelps-Dodge Co. has continued the development of the Sierra de Cobre mine, reaching a depth of 800 ft. and finding a 70-ft. body of 7% copper ore in the lower limestone; as well as taking over the Indiana-Sonora properties, on which development work was being pushed. Before the collapse, the Lewisohns had purchased from Lindsay & Talbot the Cananea Nueva, comprising 1200 pertinencias north of the Greene-Cananea. Chas. M. Schwab had taken up the Cananea Western of 398 pertinencias nine miles west of Cananea and constructed a wagon-road to the property. Guggenheim & Thompson had purchased the Cananea & Bisbee; the Mitchells, the South Cananea; Cole, Lindsay, and Talbot, the Bonanza de Cobre; and Michigan capital, the Calumet & Sonora (which is not closed down as they have a good high-grade lead product), so it may be seen that the leading copper interests in the United States were acquiring holdings there as rapidly as possible. Eleven miles south-east of Cananea the Arizpe Development Co. was opening up its 6500 acres with three shafts and was contemplating the erection of an immense reduction plant. And 20 miles south of Cananea the Fay Cananea Copper Co., with Duluth capital, was developing some 3600 acres. At Nacozari, the Moctezuma Copper Co., a subsidiary of Phelps, Dodge & Co., has closed down its smelter, but has erected a 2000-ton custom concentrator, the product from which goes to Douglas, Arizona. In the Magdalena district 27 miles southeast from Nogales, the Black Mountain Mining Co., after several years of work on a low-grade proposition, has met with deserved success, and now is making good profits with the 120-stamp and cyanide mill. Into this region many of the discharged men from Cananea have migrated on prospecting tours. The Belen Copper Co., at Cumpas; the Anita Copper Mines Co., at Corcorit; and the Cienegulta Copper Co., in the Sahuaripa district north of Ures; all have their little smelting plants and are shipping high-grade matte. And at Fundicion, 150 km. from Guaymas on the Alamos branch of the Cananea, Yaqui River & Pacific Railroad, the Pacific Smelting & Refining Co., controlled by the Douglas Copper Co., is just preparing to start up its 250-ton smelting plant, completed in November, for the treatment of its own ores and for custom business. Though the Yaquis continue to give trouble in the eastern part of Sonora, the railroads are beginning to form a network through that region and will soon drive them out, but the northwestern portion of the State is practically without transportation and has scarcely been touched by the prospector.

At the beginning of 1907 Sinaloa, rich as it is in resources, both mineral and agricultural, had but 85 miles of railroad, from the coast to its capital of Culiacan, and a short distance out from the port of Topolobampo, the western terminus of the Kansas City, Mexico & Orient. This road, however, has pushed construction work along the Fuerte river, until the grade has reached almost to the Chihuahua line, near Guazapares, a distance of 130 miles; and the Southern Pacific's Guaymas-Guadalajara line has crossed the Sonora-Sinaloa boundary and has built about 25 miles into the latter State toward San Blas, on the Fuerte river, the junction point with the Kansas City, Mexico & Orient. Furthermore, the survey of the Durango-Mazatlan line has been completed, so it is quite likely another year will see this State with two lines crossing it from east to west and another its entire length north and south. This railroad building has made such a demand on the men and animals throughout Sinaloa that, with the exception of the silver mining at Cosalá and at Copala and the gold mining at Realito and Boleo, no mining of real consequence has been done. But with better means of transportation, Sinaloa's future is assured.

To the State of Chihuahua must be given credit for marked general progress. Nor is this surprising, for aside from being the largest State in the Mexican Republic, it has had the added impetus of the Kansas City, Mexico & Orient building across its entire breadth from northeast to southwest, and the erection of a large smelting plant at its capital, the city of Chihuahua. This plant has been practically completed during the year by the American Smelting & Refining Co., and would no doubt have been blown in before this had it not been for the inability to get sufficient fuel and the lack of assurance from the Mexican Central Railroad that the supply could be maintained. The plant is of 800 tons capacity, intended principally for lead, and is thoroughly up-to-date in the economical handling of materials, with belt conveyors to and from the sampling mill and over the ore-beds, movable platforms, electric charge-cars, automatic feed, and electric engines for handling the slag-pots. East of the city of Chihuahua, on the line of the new railroad, considerable development work has been done in the way of opening up copper and zinc properties near San Sóstenes station and in the Coyame district. In the old camp of Santa Eulalia, there have been opened up hundreds of thousands of tons of comparatively low-grade (10 to 15 oz.) lead carbonate and iron oxide ores, in the following properties: The American Smelting & Refining Co.'s mines, which are being equipped with electric hoists and whence an aerial tram is to extend to the company's smelting plant; the Chihuahua and the Potosi (large zinc bodies also in this property), which are controlled by the Grant B. Selden interests in New York, and have their own railroad from the mines to Chihuahua; the Santa Eulalia Exploration Co., of Los Angeles capitalists, where in 16 months development work on

its Buena Tierra claims over 250,000 tons have been blocked out; and the San Toy in which Chas. M. Schwab is heavily interested, and which has its tramway of 4½ miles to connect with its own spur from the Mexican Central railroad; together with a number of other smaller producers. This camp alone, without further development work, could keep the Chihuahua smelter going for many years. To the west of the city, along the line of the Chihuahua & Pacific railroad, the development work has been more in high-grade properties, unless we except the Calera. This property, near Miñaca, the western terminus of the Chihuahua & Pacific railroad, is commonly called the largest zinc mine in the world, and has an immense sulphide body running about 10% lead and 30% zinc, with a garnet gangue, on which water concentration proved to be of no avail. Dry concentration was then tried and it is here that the Sutton-Steele pneumatic table has had its first successful demonstration on a large scale, and the manager, C. M. Pringle, is satisfied that it is the only method for handling the Calera ore. After crushing to 20-mesh the ore passes through an air suction classifier and onto the Sutton-Steele tables, which yields a remarkably clean concentrate, running over 65% lead, 3 to 4% zinc, and 3% iron, the middling is stored, and the tailing goes to the Wetherill magnetic separator, whence is obtained a product running from 40 to 45% zinc. At present only three tables are in commission, but they will be added to, and Mr. Pringle states that each table when running properly has a capacity of 30 tons per day. I have dwelt at length on this work because it is as a milestone in the progress of mining and milling, as demonstrating a practical method for handling these complex sulphide ores.

West of Calera the Kansas City, Mexico & Orient railroad has been pushing south and west to connect with its line from Topolobampo, while W. C. Greene (of Cananea fame) has been most active, in extending his tracks to meet the others of the Rio Grande, Sierra Madre & Pacific coming south from El Paso, building wagon-roads (a permanent blessing to that part of the country), opening up the timber-lands of the Sierra Madre Land & Lumber Co., and developing the mines that have been acquired by the Greene Gold-Silver Co., though it is a question whether he has been successful in this, but it is to be hoped, nevertheless, that his "promises to pay," which are due next June, may be taken up before that time and that he may soon again be actively at work, for his enthusiasm gives a certain impetus to such work that is greatly needed in this country. Of the other more important developments west of Chihuahua, the Rio de Plata Mining Co., 100 miles beyond the railroad, in charge of D. M. Shanks, has in an incredibly short time completed its 25-stamp mill and is shipping a rich concentrate while storing the tailing for cyanide treatment later; the Dolores, in the Guerrero district, is shipping concentrate and cyaniding the tailing; the Waterson company, in the Ocampo district, has added cyanide to its amalgamation plant; the Republica, at Morris, two days beyond Ocampo, has made final payments on the property, has erected a 10-stamp mill, is shipping out concentrate and storing the tailing; the Pinos Altos mines have been again opened by Pittsburg capital (T. N. Barnsdall and associates); the Batopilas continues prosperous; the Palmarejo & Mexican is meeting with more success since cyanide has taken the place of amalgamation, and a power-plant on the river and an immense mill at the mine for the low-grade ores are under consideration. At the extreme western border of the State, near Guazapares, which is just at present more accessible by way of Topolobampo, the rich gold mines of the Lluvia de Oro and the Calabacillas are being provided with stamps and cyanide mills, while the former is being thoroughly equipped for electric power from a 500-kw. steam turbine. In the Parral and Santa Barbara districts, the most noteworthy work

Map of Mexico, Showing the States.

for the year has been the erection of the 80-stamp mill (for cyaniding) and the installation of electrical equipment on the properties of the Veta Colorada Co., controlled by Martin J. Coudon and associates of New York; the completion of the 200-ton mill (vanners and cyanide) of El Rayo Mining & Milling Co. controlled by W. B. Thompson, of New York; the successful termination of experiments on the ores of the Tecolotes y Anexas of the A. S. & R. Co., and the starting of two units of their immense mill, which had been idle for several years, but now since April has been handling 500 tons per day of the lead-zinc sulphides; the combination of the Clarinos, Los Remedios, and Reforma as the Hinds Consolidated Mining Co., with a good working capital; and the leasing of the famous Palmilla of Pedro Alvarado for 15 years to J. A. Coram and associates of Boston. At the San Francisco del Oro, where great bodies of sulphides, into Guanacevi of the large English company on the Restauradora, the Mines Finance Co. (J. B. Farish) on the Garibaldi mines, and the Mexico Mining & Smelting Co. of Boston on the Nuevo Australia, Soto, and Porvenir.

In Zacatecas, the most important events are the completion of the 500-ton lead smelting plant of the Mazapil Copper Co., at Saltillo, which will be a custom smelter as well, though not in the sense of a competitor to the Monterrey or San Luis Potosi plants; the acquisition of the concession of Walter C. Palmer by the R. A. Towne interests, and the completion of the survey for the railroad between the Mexican Central station of Gutierrez to the towns of Sombrerete and Chalchihuites, a road that has been greatly needed, and by which the Towne interests could have saved many thousands of dollars in working their Sombrerete mines had they built the line 15

On the Road to the Mines.

running about 11% lead and 23% zinc, have been opened up, preparations are being made for experimental treatment by the Sutton-Steele dry tables and the Mineral Separation Co.'s oil-flotation process. At the camp of Nalca, which has been so long an almost one-mine camp, the Lepanto and the Ramon Corona are rapidly increasing their production and crowding the Nalca for first place, which latter it is understood the Vogelsteins were seeking for P5,000,000.

In Durango we have seen during the year a successful turn in the operations of the Velardeña smelting plant of the American Smelter's Securities Co., leased to the A. S. & R. Co.; the practical rebuilding of the Maplmi smelter of the Peñoles Mining Co., and its active entry in the markets as a custom plant; the opening of an almost new camp at Topia, by the development work of the Macdonald brothers on La Perla lead mine, the erection by them of a concentrating plant, and the expected railroad connection with Culiacan; the proving up of the immense gold quartz deposits at Indé on the Guadalupe and the property of the Indé Gold Mining Co., the consolidation of the two under the name of the latter, and the completion of its 100-ton cyanide mill; and the entry years ago. Near the city of Zacatecas, the English company operating the El Bote mine has changed over from amalgamation to cyanide, an act that it is to be hoped may presage better milling, so that the coming year may see the resumption of many old properties and the successful use of cyanide as at Guanajuato.

In Guanajuato improvement and development continue unabated; the weekly payroll has reached the nice sum of P80,000; the Guanajuato Power & Electric Co. has taken up more water rights to give additional power to the camp; the Sirena of the Guanajuato Consolidated, the first of the modern companies, has opened up an immense body of P35 ore below the fifth level, which seems to be improving with depth; the Pinguico has also greatly added to its ore reserves; the Guanajuato Reduction & Mines Co. has increased from 80 to 210 stamps, and even for this mill it is estimated there are some 12 years' supply in the old dumps to say nothing of old fillings in the company's Valenciana, Cata, Mellado, and Rayas mines; and the San Cayetano has finally been purchased from the old English company by a New York company. Greatly to the credit of this old camp may it be said that scarcely a failure has been made of

any property there that has had anything like a sufficient working capital. But of greatest importance to the future of the camp are the cutting of the Porfirio Diaz tunnel, which precludes the possibility of recurrence of the devastating floods of 1903 and 1905; the long-needed entry of the Mexican Central Railroad into the city of Guanajuato, thus cutting off untold expenses and inconveniences; and the beginning of construction work on the Guanajuato Belt Railroad, which will bring almost all the mines and mills of the camp in direct connection with the Mexican Central Railroad.

Jalisco has seen the renewal of life and the remarkable success following the re-opening of the old mines in the Hostotipaquillo district, as well as in the development work on extensions of the old veins; the entry of strong American companies in the Mascota, Real El Alto, San Sebastian, and Los Reyes districts; the opening up of the copper properties around Autlan and Ayutla; the practical completion of the 250-ton cyanide plant of the Amparo Mining Co. near Etzatlan; and the hope of cheap power held out by the Electric Light & Power Co. of Guadalajara from its contemplated power line to the above mentioned camps of the State, excepting perhaps Ayutla and Autlan.

The mines of El Oro, in the State of Mexico, have taken on a new lease of life with the finding early in June of a new orebody at 1000 ft. on the San Rafael vein in the El Oro. The workings had been getting poorer in depth and the future of the district was being despaired of until this discovery was made, for, being a sulphide body, it seems to indicate persistence of ore in depth. The completion of the power plant of the Sultepec Electric Light & Power Co. has made possible the resumption of work at many of the properties at Temascaltepec and Zacualpam, where distance from the railroad and fuel had formerly made economical working an impossibility.

In Hidalgo, also, electricity and cyanide are going hand in hand. At Pachuca, the birthplace of the patio process, the old process has had to give way to the new in the form of cyanide. The first experimental work on a large scale was done by the United States Mining, etc., Co. at its Real del Monte mines, and work is being pushed on two 250-ton plants. Learning of the success of the cyanide treatment for local ores, the owners of the Hacienda de San Francisco, one of the oldest patio plants in Pachuca, after an idleness of about six years, early in the year of 1907 made the alterations necessary and opened up as the pioneer cyanide plant in the old historic camp of Pachuca, being soon followed by La Union, another of the old patio 'haciendas.'

Oaxaca has been fortunate in the successful maintenance of the little lead smelting plant of Hammer & Williams, at Magdalena, which has been recently reorganized as the Magdalena Smelting Co. of New York, with a capital of P5,000,000 and J. H. Williams as general manager. The Oaxaca Smelting & Refining Co. has not been so fortunate, meeting with financial difficulties before being able to blow in. It was forced into the hands of a receiver, but it is believed the coming year will see it on a solid basis.

The oilfields of San Luis Potosi have rapidly increased in importance, and an immense combination has been effected (by E. L. Doheney) of the principal fields of Tamaulipas, Vera Cruz, and San Luis Potosi with the holdings of the Mexican Petroleum Co. in the latter State.

The great bodies of zinc carbonate brought good times to Villaldama, Sabinas Hidalgo, and Vallecillos, in the State of Nuevo Leon during the first half of the year, but the decline in the price of this metal and the continued difficulties about the question of duties into the United States has caused a marked falling off in the shipments.

Coahuila has become almost synonymous with coal in the minds of the people of Mexico, by reason of the enormous beds of soft coal underlying great areas in this State; and the past year has seen several companies organized as competitors to the Mexican Coal & Coke Co. of Las Esperanzas, which so long held a practical monopoly on Mexican coals. Chief of the new companies is the Sabinas Coal Co. at Rosita and Agujita, whence the combined product is over 3000 tons per day, with a 1000-ton washer both at Rosita and Agujita. This company has been strengthened in the last few months by a combination with the Mexican Mining & Industrial Corporation, an English concern, which already had ground near-by and was producing close to 1000 tons per day. Another important move was the separation of the coal lands from the other holdings of the Monterrey Iron & Steel Co., and placing them in the hands of a sub-company, to be known as the Northern Coal Co., with a capital of P10,000,000, of which P1,000,000 is to go at once into exploration and development work. Several other million peso companies are operating in these Coahuila fields.

Throughout the year the greatest difficulty has been experienced throughout Mexico in obtaining cars for the movement of all classes of material, and this has been felt severely by the mining interests, for all the railroads report that 50% or over of their total freights have been ores or supplies to and from the mines and smelters. No wonder was it then that a cry went up over the whole Republic when the railroads proposed a new tariff that would have meant an increase in the rates anywhere from 50 to over 100%, dependent upon the grade of the ore and the length of haul. The result of vigorous objection was that the Government Commission made a material reduction in the proposed tariff, but has allowed a classification into those under P25 valuation, those between P25 and P50, and those over P50, with an increase over the existing rates on the three classes of 10, 20, and 30%, respectively; though it is not intended that these shall go into effect until after there has been some clearing in the general financial situation. The expected merger of the Mexican railroads under Federal control has likewise been delayed, because of the financial disturbances.

The scarcity of labor has become intensified all over Mexico, and in many localities where there were men they could not be induced to work. Many attempts were made to improve matters by the importation of Japanese, but generally it proved a poor experiment, for the Japs were far worse than the Mexicans, and they not only did not know how to work but they did not care to work. Up to the time of the financial troubles the growth of Mexican industries was phenomenal. Notwithstanding a great reduction in the stamp law and other taxes, the Federal revenue and surplus for the year has been far greater than ever before in the country's history; the banks have shown an ever increasing reserve, and the coinage of the country, now limited to that from the mint at Mexico City, or by contract in the United States, is being constantly augmented by many millions in both gold and silver. Mexico has been checked, of course, by the depression that has affected all, but its movement is onward and upward; it cannot now be held back; its railroads, its mines, its water-power, its agriculture are all undergoing progressive development.

THE four deepest mine shafts in the world are in the Lake Superior copper region within a mile of each other. These are the Red Jacket shaft of the Calumet & Hecla Co. and shafts No. 3, 4, and 5 of the Tamarack Co. The first is vertically 4920 ft. and the Tamarack No. 5 is a vertical shaft 5130 ft. deep.

Editorial.

LONDON has felt the depression of 1907 acutely. According to *The Bankers Magazine*, the depreciation of stocks has been the worst in twenty years. In 387 active securities quoted on the London Stock Exchange there has been a depreciation of $1,710,000,000, on a nominal capital of $17,125,000,000; that is, the fall is equal to 9 per cent. In 17 leading American securities, bought and sold at London, the decline is measured by $775,000,000, or 32 per cent. These are impressive figures.

WITH THE ERECTION of the first steel column on the pediments that mark the foundation of the new Palace Hotel, there comes the promise that this famous caravansary will soon become a feature of life in San Francisco. The skeleton of the big structure will contain 6300 tons of steel, besides 1000 tons of grillage and bases. The hotel will be ready for business in about two years. Meanwhile, we are glad to chronicle the re-opening of the St. Francis Hotel, which survived the earthquake only to be gutted by the conflagration of April 18, 1906. The interior of the renovated hotel is so like its former self as to suggest, to those within the building, that the earthquake-fire was but an ugly nightmare. Mining engineers, who are necessarily nomads, will be glad to know that San Francisco now affords plenty of hotel accommodation and is once more the hospitable city of old renown.

SOON we shall have passed through the orgy of statistical misinformation that marks the beginning of every year. Scribes that must show increases of production in their county or their State, amateur statisticians that are forced to prove the advancing strides of industry in their own habitat, can take a rest and confess their sins of exaggeration. To the innocent reader of the reviews of progress in mining regions it might seem as if a veritable shower of gold or a flood of silver were about to overwhelm us; each county seems to be able to do as much as a whole State, and each State seems capable of producing enough metallic wealth for the whole Nation. The result is bewildering and most unconvincing. We doubt if any town, district, or State gains in reputation or general estimation from the corruscating Niagara of blatherumskite outpoured during the closing hours of the year. Exaggeration is futile, and it does not prevail.

BY THE TRANSFER of the control of *The Times* to C. Arthur Pearson, the leading daily paper of the world passes out of the hands of the Walter family, which has owned it for four generations. One would suppose that an event of such general interest and unusual significance would receive adequate notice, if

not intelligent comment, at the hands of our local contemporaries. The *Chronicle* gave the telegraphic news without comment, the *Call* failed to notice the fact at all, and as for the *Examiner*, since we never read that paper we cannot say what sort of stuff it printed on the subject. Undoubtedly *The Times* has lost in public estimation by its exploitation of a book trade during recent years and, even if it has not deteriorated, the number of rivals has been increased; nevertheless this great exemplar of serious journalism holds a unique position and still exerts a worldwide influence. Mr. Pearson is a clever man and has modern notions of what a newspaper should be; it will be interesting to see if he can rise to the occasion.

WE TAKE PLEASURE in publishing the article discussing the leasing of Federal coal lands. The author, Mr. H. Foster Bain, is director of the Geological Survey of Illinois, and apart from his knowledge of local conditions, he has been trained at Johns Hopkins University and by service with the United States Geological Survey, two preparations for observing carefully and writing clearly. The movement to introduce the leasing system is a direct result of the abuse of power on the part of the existing coal companies and the demonstration of an oppressive monopoly in the anthracite trade. The truly American idea of fostering individual initiative and affording free play to the adventurous spirit of the man who develops natural resources has worked out not wholly for good, in so far as it has given free rein to the greed of capitalists and the unscrupulous methods of corporations having no recognition of any obligations to the community. By the excesses of such agencies we have become receptive to government paternalism, and the reader will find that Mr. Bain has stated the case fairly and squarely.

THE ARTICLE on Nagybanya, an old goldfield in Hungary, will prove interesting. It is written by Mr. Edward Skewes, at one time in practice at Cripple Creek and then general manager of the Great Boulder Main Reef mine in Western Australia. The Hungarian gold mines described by him produced 1,554,828 kronen or $310,000 worth of gold in 1906, and the official report estimates the value of the land, offices, and buildings that cannot be removed at 13,382,498 kronen or about $2,678,000. From a mining standpoint this region in eastern Europe is one of the great has-beens of history. During the time of Trajan, who conquered Dacia and made it a province of Rome, in the first century, these goldfields were the most important in the Roman empire. As a part of Transylvania they continued to be productive and afforded matter for early geological studies. In the dumps of the old mines Roman coins have been found, the gold so pure as to be soft. It is likely that the silver-gold bullion of the mines was refined by the use of salt, with the formation of a silver chloride that is readily amalgamated. An attempt has been made to introduce modern machinery into Transylvania with a view to exploiting the low-grade ores remaining in the old mines, but the results have proved that the cheap labor of the past could give better economic resultts han the mechanical devices of today.

A Tribute to Civilization.

RETROSPECTS of 1907, and of the financial disorganization that came so suddenly last October, have been general at the beginning of the new year. The sober thoughtfulness induced by a personal experience of the late unpleasantness has led most of us to read the opinions and forecasts of individual financiers as published in the daily press of the larger cities. In the midst of the bewilderment that followed in the wake of the panic these authoritative statements are decidedly reassuring, for most of the big men talk hopefully; they emphasize the industrial power of America, the capacity for further progress, the courage and vigor of the people, and the wealth of natural resources. Undoubtedly this chastened optimism is well founded; the wealth of all classes, by reason of a series of fortunate years, is such as to enable them to meet a business reaction successfully; the number of actual failures has been small, the crops now being marketed have been bountiful and are being sold at unusually high prices; speculative activity has been sobered, not killed; if 85,000,000 people will economize even but a little they can create an enormous fund of capital in a short time. After all, the primary trouble of 1907 was the exhaustion of capital; this was felt all over the world, the increasing production of gold being futile to correct it, for the business of the nations had outrun the resources available. Most students of finance agree that within the last few years the absorption of capital into various forms of fixed investment has been the greatest ever known and until this capital becomes reproductive it ceases to be serviceable for new enterprises. Moreover, in this country the extravagant diversion of capital into Wall Street speculations had reached a pitch never before attained, causing a vast amount of money to be tied up in unproductive gambling. On the top of this it was proved that the corporate management of some of the largest industrial and financial enterprises was rotten and that one or two leaders had acquired a destructive power intensely disquieting to the investing public. Until such men as Harriman, Ryan, Gates, Morse, and Heinze can be eliminated from the management of industrial enterprises of national importance there is no safety for shareholders, who but supply the facilities whereby these gamesters play their astounding games of chance and plunder.

No more striking testimony to the advance of industrial civilization can be offered than the small number of insolvencies chronicled in the United States during the recent panic and throughout the year. In 1907 there were 11,669 failures, with liabilities aggregating $195,479,214; besides 126 banks that failed for a total of $123,736,377 as against 10,682 commercial failures for $119,201,515 and 58 banks for $18,805,380, in 1906. The increase of insolvencies is extraordinarily small when we consider the volume of business transacted and the violence of the panic that convulsed the commercial

world in October and November. Of course, many weak concerns were bolstered up and many individuals were kept from bankruptcy by making a heavy sacrifice of their resources, and the result to many of them may have come perilously near to utter destruction, but it stopped short of absolute failure, and that meant much, not to them only but to the general restoration of credit in the community. Nowadays, the transfer of money by cablegram, the flashing of quotations on stocks to every corner of the globe, and the facilities afforded by a marvellously developed system of posts and telegraphs, have widened the range of business transactions and spread the base of credit to such an extent that panics are no longer local. If one community is in trouble, another gets a fit of the nerves; no city and no country is independent financially of the doings of its neighbors, when even distance ceases to be a barrier to neighborly responsibility. Viewed in this light it is astonishing that the sudden and violent collapse to credit in the last quarter of 1907 did not precipitate worse results. Despite revelations of plunder and exposures of corruption, men trust each other as they never did in any preceding period of history. Civilization is not a failure and the Caucasian is not played out.

Assisting Graduates.

BEWICK, MOREING & CO. deserve the gratitude of graduates from the mining schools, for this company has established a system by which it gives young fellows a chance to learn their profession. It is a sort of apprenticeship, modified to modern conditions. For several years now it has been the custom of this engineering firm to take a stipulated number of men from the Royal School of Mines, London, on the recommendation of the council of that technical college, and grant them facilities for taking a two years' course in mining and milling at the mines managed by the company. These students are expected to do the regular work alongside of the regular employees and they receive the standard wages. For instance, if a graduate is received at one of the West Australian mines, he may spend one month with the sampling crew or the timber gang, drawing pay at $2.75 per shift; in the next month he may be assisting the surveyor at $20 per week, and in the month following he may be in the cyanide plant receiving about $3 per shift. At the end of two years of varied labor, such a young man has been both tested and developed; he is eligible for a place on the permanent staff and, as a matter of fact, a number of these graduates have obtained responsible posts at the mines. Arrangements of a similar character have been made with the universities at Sydney, Melbourne, and Adelaide, the capitals of three Australian States. It is not necessary to emphasize the advantage of this method of promoting engineering education. Nothing could be more practical or more kind. The young aspirant for a place in the profession is able to get a sound groundwork of practical knowledge, while paying his way, and even saving some money. We advise those that succeed in saving money in the days of their apprenticeship, to spend it in travel, which is an excellent supplement to local experience. In the meanwhile, this reference to the subject is meant not so much for the information of mining graduates as it is intended to serve as a suggestion to the successful managers of mines and smelters, pointing out to them how they can help the young fellows and do honor to themselves. It is a more practical form of assistance than the gift of libraries or the donation of medals.

Smoke Suits.

THE true nature of the larger part of the agitation against the smelters in Utah and Montana is now made manifest. In the Salt Lake valley and in that of Deer Lodge, the farmers have complained that the reduction works have emitted fumes highly destructive to their cattle and crops. They have harrassed the smelting companies with lawsuits and injunctions, protesting loudly that they were entitled to the pursuit of happiness and the cultivation of their farms, even if the mines were closed down for lack of a local ore market. The farmers have rights and they are entitled to assert them, but we have always insisted that much of the organized agitation against the smelters was maintained in the hope of blackmail, that it was anti-social in so far as it disregarded the wider interests of the community at large, and that it would end in outlawing an industry just as much entitled to consideration as that of the man who cultivates the soil or breeds cattle. On the other hand, it must be allowed that the smelter people have not always shown a proper regard for the welfare of the community, and they have exhibited poor judgment in erecting smelters on sites likely to provoke a nuisance and invite litigation. However, the fact now is that the farmers in the Salt Lake valley are willing to let the Utah Consolidated Copper Company proceed with its smelting operations if but the sum of $125,000 is paid to them. This blackmail was originally $300,000; by bluffing and counter-bluffing it has been reduced considerably. The smelting company is willing to pay $100,000, but not a cent more—so it is stated. The outcome will be awaited with interest, but the main point is that the farmers are evidently public-spirited for revenue only, there is no principle at stake save that of highway robbery, no purpose save sublimated selfishness. In Montana also, there is a rumor that the Amalgamated Copper Company, controlling the Washoe smelter, is to ward off the legal assaults of the embattled farmers of the Deer Lodge valley by making a settlement, which contemplates nothing more or less than the purchase of all the farms at a big price, after the courts have passed judgment on the small amount of injury actually done to the land or the cattle on it. We shall be surprised if these developments in Utah and Montana do not cause a revulsion of feeling and lead to a refusal of support in future to proceedings from which all disguise has been stripped, showing them to be simply the blackmailing of a metallurgical industry essential to the development of our mineral resources.

Personal.

LESTER W. STRAUSS is still in Peru.

ALGERNON DEL MAR is here for a few days.

THOS. J. BARBOUR is now a resident at New York.

DOUGLAS WATERMAN goes to Chile on January 17.

H. C. HOOVER has returned to London from Burma.

COLIN TIMMONS is residing at Taxco, in Guerrero, Mexico.

J. H. MEANS has been studying the sulphur deposits of Sicily.

CHARLES A. CHASE has an office in the Equitable Bdg., Denver.

GEORGE J. BANCROFT is now editor of *Mining Science* at Denver.

E. J. CARLYLE is on his way from New York to Perm, in Russia.

W. H. LANDERS has moved to 160 Sansome St., San Francisco.

F. W. SMITH has been examining mines near Zacatecas, in Mexico.

PERCY A. BABB has opened an office at Calle de Gante 12, Mexico City.

SCOTT TURNER has returned to San Francisco from Manhattan, Nevada.

ARTHUR R. TOWNSEND has his office now at 52 Broadway, New York.

ERNEST A. HAGGOTT has an office now at 500 Hellman Bdg., Los Angeles.

THOS. G. DAVEY has opened an office at 210 Finsbury Pavement House, London.

WAGER BRADFORD, on his return from South Africa, is at Westernville, New York.

W. L. COBB has opened an office in the Merchants Exchange Bdg., San Francisco.

W. F. COPELAND, manager for the Cariboo Con. Mining Co., B. C., is here for the winter.

C. W. PURINGTON is now at London, but he expects to return to Eastern Siberia shortly.

OSCAR B. PERRY has returned to New York after spending the holidays in San Francisco.

D'ARCY WEATHERBE has resigned as manager for the Capillitas Copper Co. in Argentine.

PHILIP R. BRADLEY has left San Francisco on his return to the Peters mine, in British Guina.

ELWYN W. STEBBINS, formerly in the Chronicle Bdg., is now in the Mills Bdg., San Francisco.

WALTER NEAL is superintendent of the cyanide annex of the Dos Estrellas Co., at El Oro, Mexico.

ATWATER, LINTON & ATWATER have an office now at 52 Broadway, New York, and at Magdalena, in Sonora, Mexico.

E. P. JONES, lately mechanical engineer with Bewick, Moreing & Co. in Australia, is now chief engineer to the Risdon Iron Works, in San Francisco.

DONALD B. GILLIES, who was recently made president of the San Toy Mining Co., is spending a few weeks at the company's mines in Santa Eulalia district, near Chihuahua, Mexico.

Mineral Production of British Columbia in 1907.

Gold, placer	35,000 oz. at $20.00	$700,000

General Mining News.

ALASKA.

A body of sulphide ore which is said to carry good values in copper and gold has been found by D. Nicol in developing his mining location at Karta bay, in the Ketchikan district. This property was bonded once, but was exploited for speculative purposes, and finally reverted to the original owner, who is vigorously prosecuting its development.—— At the Lon-de-Van galena mine, near George inlet, an adit has been commenced; it is to be 800 ft. long and cut the lode at a depth of 575 ft.—— It is reported that at the Niblack mine there was found recently a body of the best ore known in the mine.——At the Held-Bach mine, in the Juneau district, a cross-cut on Dec. 18 was 30 ft. in the lode; the ore exposed is of better quality than that found on the surface. ——About 1200 men were employed at the Treadwell mines in December; more miners were arriving on every boat.—— In the Council district of Seward Peninsula, the Homestake Mining Co. has discontinued prospecting with a drill and has begun to sink a shaft.

ARIZONA.

COCHISE COUNTY.

The Savage Gold & Copper Co. intends to begin shipping ore to the Copper Queen smelter at Douglas as soon as the necessary arrangements can be made. The ore carries copper and silver; it is largely silica, which can be used at the smelter as converter lining. A new road is being built to facilitate the hauling of machinery to the mine and ore to the depot.—— Development at the Bauer group of claims, six miles east of Bisbee, is said to be resulting satisfactorily; the deepest shaft is claimed to be entirely in good ore.—— The strike in Bisbee was declared off by the Western Federation of Miners at a special meeting held on Dec. 26.—— Duffner Bros. have found some ore at the Nippers mine; it carries light value in copper and contains much manganese, iron, and calcite.—— Clarence May is sacking ore at his mine in Round valley; the value is chiefly in silver, but the ore carries from 2 to 24% copper. From six carloads of ore that have been shipped the net returns varied from $5.50 to $35.50 per ton.—— At the Bisbee-Sonora Development Co.'s mine, in the Chiricahua range, the entire breast of the adit is ore; it is expected to begin shipments soon.——The Mountain View Development Co. is driving a cross-cut from a point 160 ft. down the shaft to get under a body of ore that was found 100 ft. higher; 10 tons of it yielded $106 per ton.—— A small force of men is working on the property of the Manhattan Development Co.—— At the Scanlon mine a fine body of ore was recently found.

GILA COUNTY.

An adit has been begun at the Yellow Metal mine in Lost gulch, to cut at a depth of 100 ft. a vein which recently attracted attention on account of the discovery in its outcrop of a pay-streak 1½ in. wide which assayed $7000 gold per ton. E. F. Kellner is the owner.——Ore running from $6000 to $10,000 gold per ton is reported to have been found in an old shaft on the Emmiline claim of the Radium Mines Co. This claim has yielded much silver ore in the past.——The Old Dominion company is operating four furnaces, two of which are running entirely on slag from the dump. This slag contains 2½% copper. The company is daily hoisting from its mines 350 tons of concentrating ore and 250 tons of smelting ore. The output from its smelter is over 2,000,000 lb. copper per month; 70% of this is derived from its own ores.——The three-compartment working shaft of the Arizona Commercial mine is now down 100 ft.——Excellent progress in development is reported from the Fumarole mine in the Gila mountains.

GRAHAM COUNTY.

A carload of high-grade manganese-copper ore has been shipped from the Gold Belt mine to the Shannon smelter. The company is also making up a carload of its high-grade gold ore.——The Shannon Copper Co. is preparing for the enlargement of its two old furnaces so that it may have a smelting capacity of 3,000,000 lb. copper per month.—— The Arizona Copper Co. has completed one of the best smelter runs in its history; the product for December was 3,000,000 lb. of bessemer copper.——The mines of the New England & Clifton Copper Co. have been closed, as the company has been under too heavy expense to continue operations at present metal prices.——At the Gibson mine between 40 and 50 men are working; about 250 tons of sulphide ore are shipped monthly from this mine to the Old Dominion smelter.

MARICOPA COUNTY.

Construction work on the new mill at the Monica mine is progressing satisfactorily. A wagon-road has been finished to the mill and men are now grading for the cyanide plant. Operations in the mine have been suspended until the mill is finished. The Monica lode is opened by an adit at a depth of 1000 ft. There is enough ore on the dump to keep the mill in operation for several months.——On the property of the Merchants Mining Co. there is said to be developed at the depth of 165 ft. a lode four feet wide, of which 18 in. is ore that carries 67% lead, 40 oz. silver, and

Map of Arizona.

$25 gold per ton. At the depth of 300 ft. the lode is 26 ft. wide, but the ore is low-grade.

MOHAVE COUNTY.

A 40-hp. hoist has arrived at Yucca for the McCracken mine. The Palo Verde Mining Co. is now cleaning out the old drifts, re-timbering openings, and getting things in shape for extensive work. Accomodations have been prepared for a large force of miners; the camp promises to become one of the most important in the county within a year. J. L. Witney is manager.——The report has reached Kingman that J. P. Richardson has made a wonderful strike of gold ore in the Union Pass district.——J. D. Spargo will keep a force of men at work during the winter at the Brown mine at Stockton Hill which he has leased from the C O D Mines Co.——The Gold Road mine has been closed pending the settlement of difficulties between the French and American shareholders.——It is reported that an important discovery of ore has been made at the German-American mine near Vivian. The property has a 10-stamp mill but it has not been operated from lack of water; it is now expected that water for the mill will be secured from the Victor Gold Mining Co.'s pumping plant.—— The Chloride Gold Mining Co. has leased its Samoan mines to Roy Wright. Work is progressing and a shipment of good ore is now ready.——At the Gladstone mine driving the

adit has exposed heavy lead ore carrying value in gold and silver.——A large amount of machinery for the Tom Reed Mining Co. is passing through Kingman.—— The mill treating ore from the Idaho mine is running smoothly; by means of magnetic separators a clean zinc product is being made. A large body of ore is exposed by drifts from the bottom of the Idaho shaft.

PIMA COUNTY.

The Growler Copper Co. is installing a new hoist and engine at its mine, 65 miles south of Gila Bend. The main shaft is 250 ft. deep, and there are 175 ft. of drifts. Development is to be pushed, and the company expects to be shipping ore in a short time.—— Ore carrying gold, silver, lead, and copper is being shipped to the El Paso smelter from the mines of the Sultan Gold Mining Co., which are under lease to C. S. McHenry and A. Hoover.—— The Mansfield company is sinking a shaft to the 550-ft. level in the Sweet mine; it is mining ore on the 250-ft. level. Ore shipments are frequently made from the Black Cat mine to the El Paso smelter.—— The Tucson Consolidated Copper Co. is working at the Old Pueblo mine with a reduced force of men; the shaft, which is now down 175 ft., is to be continued to a depth of 500 feet.

YAVAPAI COUNTY.

The mill is practically completed at the Dunkirk mine in the Slate creek section; the ore-shoots exposed in the upper and lower adits are improving under continued development. A. H. Mitchell is superintendent.—— The shaft at the Verde Grande mine in the Jerome district has penetrated slate carrying sulphides; this shaft is 419 ft. deep.—— The Haynes Copper Co. being unable to handle the water flow with a whim, has shut down, awaiting the arrival of machinery.—— The Arkansas-Arizona mine is temporarily closed on account of water.—— At the Boston-Jerome mine the shaft is down 128 ft., exposing good ore.——The road to the Mescal mine is nearly completed; it is expected that development of the mine will begin soon.——The Arizona Placer Mining Co. is preparing to test its ground in the valley of the Hassayampa river to determine the advisability of erecting a large dredge.——At the Venezia mine, Frank Olin, a lessee, has found gold ore of a width of 4 ft. in a shaft at a depth of 82 ft.; a whim is being erected to enable sinking to a much greater depth.——E. H. Eplustill, Henry Price, and Willis Spence have 2 ft. of high-grade concentrating ore at the distance of 100 ft. from the portal of the Portland mine, near Palace station.——At the Buster Brown mine, Leroy Spence and Burt Evans are sinking a shaft on a lode which at a depth of 40 ft. has 2 ft. of good ore.——At the Jaunita mine a small force of men is driving an adit; it opens an orebody 8 ft. wide which is said to carry $22 per ton.——O. I. Tawney made a small shipment of ore from the Peck mine; it carried 750 oz. silver per ton.——The Leontina Consolidated Mining Co. has purchased the Revenue group of claims in the Big Bug district. Four of the locations have been made on a large porphyry dike which has been explored along the foot-wall by a shaft 114 ft. deep; in the bottom of this is ore carrying 4.9% copper and a sufficient quantity of gold to make the total value $45 per ton. The new owners intend to sink the shaft to the depth of 600 ft. and explore the dike by several hundred feet of cross-cuts and drifts.——At the First Home mine, in the Big Bug district, 8 tons of ore were taken from the 240-ft. level; this ore carried 50% lead, 20 oz. silver, and $20 gold per ton.——The people of Wickenburg are excited over the prospect of the Vulture mine soon resuming operations. ——A 53-lb. bar of gold from the Octave mine was on exhibition in Prescott on Christmas. The company that owns the Octave mine also owns the Mudhole mine at Walker, on which it is planning to resume work in a short time.—— W. M. Nellis is preparing to install a hoist and pump at his French Lily mine in Crazy basin.——The Haynes Copper Co. has purchased a double-drum hoist and an air-compressor powerful enough to run 12 drills.——S. Morrison and son have found some good ore in the Windsor mine in the McCabe district; it is from one inch to a foot in width and carries from $20 to $80 gold per ton.

YUMA COUNTY.

A carload of very rich ore has been shipped from the North Star mine; it is claimed that practically every piece of it carried gold visible to the unaided eye. Much of it was stolen. The value is estimated at $6000 to $7000 per ton. ——Plans are being made for the construction of a 50-ton smelter near Parker on the Colorado river.

CALIFORNIA.

CALAVERAS COUNTY.

Associated with the quartz vein in the Mammoth mine there has been found a streak 3 to 4 in. wide of red clay that is highly impregnated with gold, an assay giving it a value of $300 per ton.——The Stockton Ridge Consolidated Gravel Mining Co. is driving an adit to reach an old river channel; this adit is now over 1400 ft. long and it is expected to reach the gravel within another 400 ft. Stephen Hughes is superintendent.——Tom and Hugh McSorley and Edmund Stocker are working a drift mine near the old Boston mine; recently they secured 7 oz. of gold from two panfuls of gravel.

ELDORADO COUNTY.

A test run on 100 tons of ore from the Vivian mine is said to have given a satisfactory result.——A. Goldsworthy and Paul Ricci are developing a promising lode at the Oakland mine.——Mrs. L. E. Pease has abandoned work at the Garibaldi mine near Greenwood, but has a crew of men at work at the Geo. Bower mine.——At the Marshall mine in the Mount Pleasant district, a pipe-line is being laid preparatory to installing power-drills in the mine; the power will come from the air-compressor at the Mount Hope mine.

INYO COUNTY.

The new mill at the Casa Diablo mine is practically completed; F. J. Girard of Berkeley, Cal., has been engaged to take charge of the cyanide plant. A large body of good ore is said to be exposed in the Dry Bone drift.—At the Red Rose claims, near Bishop, active operations for development have begun. Very rich specimens have been secured from the outcrop of the lode; some on exhibition in Bishop are estimated to contain $50 per lb.——Zinc ore has been found by H. M. Gibson and P. W. Forbes in developing a silver-lead lode in Black canyon; its quantity has not been determined but it is wider than the adit.——Near Chrysopolis a number of locations have been made on presumed rich placer ground.——A big strike of ore is reported from the old Cerro Gordo mine near Keeler. It was found in sinking from the 850 to the 900-ft. level. The old smelting plant is being rebuilt.

NEVADA COUNTY.

(Special Correspondence).—Sinking is going on at the Central mine and considerable development work is being done below the 4000-ft. level.——A large force of men is steadily employed in development work at the Empire mine; a large tonnage of high-grade ore is being handled, and the mill is running constantly.——Promising ore is being developed in the Niagara mine; several men are employed, and much development work is being carried on. ——Extensive development work is going on at the Union Hill mine, and good ore has been encountered.——At the Kenosha a small force is developing a promising shoot of ore. The main orebody continues to show well with increased depth.——Active work has commenced at the Nevada hydraulic mine at Red Dog. The restraining dam is fulfilling expectations admirably, and the management expects to have a successful season.——The Junction mine has been closed. It is expected that active operations will be resumed in the spring. The management contemplates the construction of a tram-line before resuming work. The closing of the property is attributed to the financial stringency.——A ledge running from five to seven feet wide is being developed in the Barton mine. The ore carries from 50c. to $2.50 per ton free gold. The sulphurets carry good values. The advent of winter has forced the suspension of construction work on the new 30-stamp mill. This will be completed in the spring.——The strike recently made in the Champion mine continues to show up well; good ore is coming from the Home shaft.——High-graders are causing the management of the Plumbago mine con-

siderable trouble. An arrest was recently made, but no evidence could be secured to hold the suspect.

Grass Valley, Dec. 30.

E. D. Dean is sinking an incline to develop the Royal gravel mine at Selby Flat.——The Maryland mill has finished crushing 150 tons of ore from the Golden Gate mine; the lessees of this mine have a year to operate yet and are retimbering the old shaft and sinking it deeper. W. P. Martin is superintendent.——The adit at the Snow Point mine is being driven ahead; three men will be employed until spring.——D. Stewart and J. Waarden are driving an adit to open the back channel in the Loosenes gravel claim near Gott's ranch.——L. B. Clark and Henry Goering are opening up a placer mine near Round Mountain and the gravel they are washing is said to be giving good results.——Ten stamps have been added to the mill at the Yuba mine; 20 stamps are now dropping regularly on good ore, part of which is brought on the rebuilt tramway from the Mayflower mine. About 60 men are employed at the Yuba and Mayflower mines; Charles A. Marriner is manager.——Seventeen tons of ore taken at random from the Norambagua mine have been crushed at the Southern mill; the yield was $29.75 per ton. Nine men are employed at the mine in driving north toward a presumed large ore-body.——Preparations are being made for reopening the Normandie mine, owned by Frank Dulmaine. There are two known lodes, on one of which a 40-ft. shaft has been sunk. The property has been bonded to several young men from Reno, Nev., each of whom has taken a course in mining engineering.——It is reported that on December 26 Deer Creek carried away the ground-sluicing plants from several placer mines near the Newtown bridge.——The new 10-stamp mill at the Ancho mine near Graniteville is in operation; some good ore is being taken out of the mine.

PLACER COUNTY.

The dredge at the Cash Rock property has been launched; it is 84 ft. long and 44 ft. wide. The machinery is being put in place; 20 men are working on it.——Lukens & Sons have installed a steam-hoist at their mine at Hoggs Diggings and have taken out some good ore.——At the Herman mine 25 men will be kept at work during the winter.——A. Moer is driving a second adit at the Vineyard mine near the Wisconsin Hill-Yankee Jim toll-road.——The retimbering of the Grey Eagle tunnel is in progress.——A number of men are opening up the Polar Star mine.——At the McGeachen mine 20 men are taking out gravel; the new hoisting plant at the Juniper shaft is finished.——Four men are working at the Gleeson mine; the adit is about 400 ft. in good paying gravel.——At the Hidden Treasure mine 25 men are at work; a drift is being extended toward the Mountain Gate channel which it is expected to reach within 300 ft.——Henry McAuley has a number of men working in the Drummond mine; a hoisting plant is to be put up and a shaft sunk on the lode.

PLUMAS COUNTY.

The Plumas-Mohawk mine was closed some time ago, as no preparations had been made to run during the winter.——Four men are developing the property on Clearmont Mtn. that was recently purchased by W. E. Oddie. An arastra has been erected for the purpose of prospecting the ore. The vein is said to carry $10 to $25 gold per ton, as determined by mill-test.——O. A. Wheelock has taken a lease on the Taylor Plumas mine at Crescent Mills and intends soon to begin development work.——A. M. Hansen is opening up a placer mine about four miles east of the Jo Gill ranch.

SHASTA COUNTY.

At the Midas mine, at Harrison Gulch, about 70 men are employed. The 20-stamp mill continues in operation except when heavy snowfalls interfere with it. The ore developed is expected to keep the mill running for six or seven months. L. A. McIntosh is manager.——Senator F. W. Leavitt of Oakland has purchased a quarter interest in a group of claims north of the Mammoth mine near Kennett; development of the property is to be begun soon.——The completion of the Mammoth Copper Co.'s railroad bridge at Quartz enables the resumption of ore shipments from Old Diggings and Quartz Hill to the smelter at Kennett.——A 5-stamp mill has been built in Grizzly gulch by John Martin and son, to treat ore from the Trucott mine, six miles from Whiskeytown; there is said to be enough ore developed to keep the mill running for years.——The remodeling of the Bully Hill smelter is practically completed and the plant will resume operations as soon as the Sacramento Valley & Eastern railway has been finished to it. The smelter has been rebuilt on a larger and improved pattern, and over $100,000 has been expended on this work.

SIERRA COUNTY.

An upraise is being made in the South Fork adit in the hope of reaching an old channel deposit.——At the Keystone mine near Sierra City six men are stoping ore; the mill will resume operations as soon as sufficient water is available.——The Sovereign mine has been closed for the winter.——At the Hayes mine a small crew of men is working under the direction of Frank Summersville.

SISKIYOU COUNTY.

The Morrison & Carlock mine in Quartz valley and the Eastlick quartz mine near Greenview have closed down.

Map of California.

——The company operating on Sugar creek has been unable to get coin with which to pay the men, but it is believed that it will continue to operate.——The Milne Bros. are working their hydraulic mine at Johnson's Bar.——George Magoffey & Co. are rigging up their hydraulic mine on Mill creek near its junction with Scott river.——The owners of the Yellow Butte mine are preparing for a shipment of ore to the Mammoth smelter at Kennett.——An electric power plant has just been completed by the California Consolidated Mining Co. at Sawyer's Bar. The big flume, ditch, and water-right of the Salmon River Hydraulic Co. were purchased. Power will be supplied to the Ball group of mines and it is intended that next summer the line will be extended to the King Solomon mine.

TRINITY COUNTY.

The Bonanza King mine is in the hands of a keeper following the recent attachment of the property for wages due the 49 miners who worked in it.——The preliminary survey has been completed for the State highway that is to connect the central part of Trinity county with the road system of Humboldt county. When built this road will be of great benefit to the mining interests of the northwestern portion of the county.——A full force of men is working at

the La Grange hydraulic mine.——At the Globe mine an adit is being driven to connect with the Chloride mine, which is on the opposite side of the mountain.

TUOLUMNE COUNTY.

The Longfellow mine at Big Oak Flat has closed down; the employees are proposing to file liens against the property for unpaid wages.——The Montezuma Tunnel Mining Co. has leased its gravel mines to J. Hagman, who will continue driving the adit and inaugurate operations on Turner flat.——Thirty stamps are dropping in the Harvard mill; when new concentrators have been installed, 10 more stamps will crush ore.——The Eagle-Shawmut mine is in operation on a 9½-hr. workday; a force of 200 men is employed.

NEVADA.

ESMERALDA COUNTY.

Governor Sparks has called an extra session of the Nevada Legislature to convene on Jan. 14, to pass new laws for the policing of the State. Two full companies of soldiers have been ordered to remain in camp at Goldfield until after the Legislature adjourns. The remainder of the troops left on Jan. 3 for their various stations in California. Pickets and guards have remained on duty at the mines but there has been no trouble between them. On Dec. 27 a complaint was filed before the United States District Court at Carson City, by Attorney W. H. Bryant, on behalf of the Goldfield Consolidated Mines Co., praying for a writ restraining the Western Federation of Miners from interfering with the operations of the mines, also asking that the Federation be dissolved, as the organization is classed as a conspiracy. Judge Farrington set Jan. 3 for the hearing on the petition for a temporary injunction. Considerable progress has been made by a movement to form a new union entirely separate from the Western Federation of Miners and based upon the old Virginia City Union. Many of the miners are becoming convinced that the Goldfield Mine Operators' Association intends to remain firm in its determination never to employ members of the Federation, and they are beginning to consider any plan whereby they can go to work as union men and still meet the demands of the operators. Indeed, numbers of them are breaking away from the Federation and are going to work under the card system and under the new scale of wages adopted by the mine owners. On Jan. 4, the Combination Fraction mine, after an idleness of five weeks, resumed with three shifts, many of the men being former Federation men. On the same day, the Mohawk proper resumed work with former Federation men and new men from California and Utah. The two Becker leases at the Atlanta mine began work with new men brought into camp by the manager. The Von Polenz lease at the Florence mine also started up with a full complement of men.——C. W. Merrill, of Lead, S. D., has been in Goldfield for the purpose of looking after the erection of the 500-ton mill of the Goldfield Consolidated company on the west slope of Columbia Mtn., at an estimated cost of $700,000.——The management of the Little Florence company of Goldfield has made arrangements with the American S. & R. Co. for the receipt of all the high-grade ore that can be shipped over the railroads to Denver; over 2000 tons of ore on the dump are said to contain an average of $250 per ton.——The plant of the Goldfield Chlorination Mill Co. near Columbia is rapidly nearing completion.——At a depth of 500 ft., the Kansas City lease on the Velvet claim is said to have penetrated an orebody 12 ft. wide, chiefly low-grade, but displaying some rich seams.——German miners have secured a lease on the Milltown Fraction claim and will soon begin work.——The shaft of the Gotwaldt lease at the Combination mine has reached sulphide stringers that yield assays as high as $20 per ton; it is expected soon to find the extension of the famous old Reilly pay-shoot.——The Oddie-Gardner mill is to be used to treat ore from the producing leases in the new Stimler district.——Plans are under way for the building of a copper matte smelter at Mina; some of the prominent mine owners of Goldfield and Tonopah are said to be interested in the project.

A new copper district has been found near Luning; many locations have been made. On the Green Mystery claim, a 20-ft. shaft has been sunk in a lode whose outcrop is 60 ft. wide. The shaft, it is said, exposes two feet of ore which carries 10 to 12% copper, 8 oz. silver, and $2 gold per ton.—— The mines of the Goldfield district will have to pay $197,830.33 bullion tax. This tax is at a rate of 4.77% of the net receipts of the mines. All of it goes into the county treasury except three-fourths of one per cent, which goes into the State treasury.—— Twenty stamps are dropping in the Pittsburg-Silver Peak mill at Blair; it is expected that the entire 100 stamps will be in operation soon.——At the Garfield mine three carloads of ore running in value from $50 to $600 per ton have recently been taken out; about 25% of the value is in lead. A cyanide plant is to be erected soon.—— The control of the Nevada-Alpine mine at Lone mountain has passed into the hands of J. S. McCord & Co., Philadelphia brokers. The property will be under the management of S. A. Brady, superintendent of the Belmont mine. The Nevada-Alpine is a lead-siver mine; much ore has been shipped from it.

NYE COUNTY.

The Tonopah Mining Co. has issued a statement covering the operations for the last quarter. The mill was closed about ten days to permit of a change in fuel from coal to oil, which change should reduce considerably the cost of operation. The mill was also closed down for about a week on account of a strike on the railroad. The recent fall in the price of silver decreased the company's earnings during the past three months to the extent of about $40,000. However, the net earning of the company for September, October, and November amounted to $305,526.64.

The ore shipments over the Tonopah & Goldfield railroad for the week ending Jan. 2 as reported by the Western Ore Purchasing Co., were as follows: Tonopah company, 285 tons; Jim Butler, 53; Tonopah Extension, 111; Midway, 189; total, 638 tons. The Tonopah company sent 2160 tons, the Belmont company 800 tons, and the Montana Tonopah 1100 tons to the mills. Thus the total output of the Tonopah mines was 4698 tons of an estimated value (the shipping ore being valued at $70 per ton and the milling ore at $30 per ton) of $166,460.——Plans are being drawn for a stamp-mill of 300 tons daily capacity at the Tonopah Extension mine. The pulp from the batteries is to be reground in tube-mills and then cyanided under air pressure in rotating barrels.——By driving a cross-cut north on the 800-ft. level of the Midway mine, a large low-grade vein has been found at the contact of andesite and dacite; it is not yet possible to correlate it with any other vein in the Tonopah district.——The Montana mine is developing below the 765-ft. level and as there is no geological reason why ore should not be found below the dacite intrusion that has given so much trouble in Tonopah mines, the result of this work will be of great benefit to the district.——The Jim Butler mine is producing the customary quantity of ore; the new compressor is working satisfactorily and rapid progress is being made on all levels.——The Quincy Mining Co. intends shortly to resume operations at its mine near Crow Springs.——At the property of the Washington-Nevada Mining Co. on Lone mountain driving on the lode has been in progress for several weeks; the ore carries lead, silver, gold, copper, and zinc.——The Tonopah Mining Co. has discontinued shipping ore to the smelters, but the mill will be run without interruption to its full capacity of 350 tons per day.——At the Manhattan Pine Nut Extension mine an 18-in. vein of ore has been found; there is also on the property a 30-ft. shaft the bottom of which is in ore carrying $7 per ton.——At the Tip Top mine high-grade milling ore has been developed; there is also a narrow seam of very rich ore, showing much free gold.——The Davis-Shea lease on the Union No. 9 claim at Manhattan is producing much high-grade ore; the lessees are doing all in their power to get this ore out rapidly and are employing every man that they can make room for.——J. W. Travers is preparing to begin development work on the tungsten-bearing lodes of the Round Mountain-Philadelphia and Round Mountain-Nugget groups of claims which lie east of the town of Round Mountain; the ore also contains gold.

The cross-cut on the 200-ft. level of the Mineral Hill mine

at Manhattan cut the lode on December 14. The ore is five feet in width. Assays of $24.64 and $109.36 gold per ton were secured from it. The best ore is in the centre of the lode. The gold is largely free but the vein also carries sulphides. Good gold pannings were obtained across the entire width of the vein in a cut 200 ft. west of the shaft.——The Smuggler Mining Co.'s shaft at Atwood is down 60 ft.: it has yielded some fine ore.——At the Gold Crown mine a gasoline hoist is being installed. As soon as the mine has been cleaned out, hoisting ore will be resumed.——At the Gold King mine the timbering of the shaft has been completed; a good body of ore was developed by this shaft.——The Pactolus mine is being worked by lessees; they have on the dumps about 100 tons of shipping ore and 250 tons that will average it, it is expected, about $25 per ton.——At the Tecopa mine it has been found necessary to reduce the tonnage produced; this gave rise to a rumor that the mine had closed. It is the intention of the company to construct a spur from the mine to Tecopa siding of the Tenopah & Tidewater R. R.; also to erect a smelting plant; to build first a 500-ton unit and ultimately to increase the capacity of the plant to 1000 tons.——The Nevada Smelter & Mines Corporation has installed a large Snow station-pump on the 400-ft. level of its mine at Tybo; a 100-hp. boiler and a 6-drill Ingersoll compressor have also been added to the plant. The mine has been cleaned and prepared for stoping the rich ore that has been found on the 300 and 400-ft. levels; this ore carries silver, lead, and gold.——A contract has been let for the building of a 50-ton mill at the Patton-Paul-Rule lease at the Round Mountain Daisy mine.——At the Homestake mine in the Bullfrog district 40 men are engaged in preparing the foundation for the mill.——Osbourn & Williams are sacking high-grade silver ore at their mine four miles southeast of Round Mountain. Some of it is said to contain a sulphide of copper, bismuth, and lead. The clean-up of the Sunnyside mill for November, it is stated, was nearly $20,000.——Work in the western portion of the McNamara mine has continued during the lawsuit which has prevented work in the remainder of the property; a 60-ft. raise has been made in a vein four feet wide, containing ore of shipping grade.

WHITE PINE COUNTY.

At least two weeks more must elapse before the three imprisoned men in the Alpha shaft of the Giroux property can be brought to the surface; all the ground encountered by the rescuers in the shaft to a depth of 569 ft. had been loosened by the shifting of the timbers and earth which caused the cave-in. On Jan. 1, 400 ft. of earth intervened between the entombed men and liberty.—— For three months ore from the mine of the Boston-Nevada Gold Mining Co. at Osceola has been milled in the Whitney 20-stamp mill.—— It is reported that 45 men will soon be put to work on the big tunnel which is to convey the water of Duck creek through the range to the smelter at McGill.

OREGON.

JOSEPHINE COUNTY.

A notable increase in equipment has been made at the Simmons, Cameron & Logan placer mine in order to handle the deep gravel deposits on the property.——At the Baby mine, near Jump-off-Joe creek, a small force of men is working; a 5-stamp mill is in operation.——At the Lucky Bart mine J. E. Kirk and son are preparing to make another mill-run.——J. H. Beeman is doing development work on the Alice mine.——At the Hinkle mine Bart Carter and Fritz Hammersly are preparing for a test run of ore at the Bart mill.——The stamp-mill at the Tin Pan mine has been completed.——At the Buzzard group of mines a contract has been let for a 100-stamp mill, which is to be completed within six months.——A Kent crushing mill of 100 tons daily capacity and a cyanide plant of the new Rankin type are to be installed at the Elk Creek gold mine.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Insurgent Gold Mining Co. has leased the Insurgent group of claims to Wm. M. Crummer for six months; the lessee has made a shipment of 35 tons of ore of a value of $18 per ton, of which $15 was gold.——The face of the lower drift of the Copper King mine at Keeler is reported to be in high-grade ore.——The new adit at the Copper Key mine is over 150 ft. long and shows small stringers of low-grade vein-matter; progress is reported at about 9 ft. per day. Another adit, to cut the vein at an additional depth of 195 ft., has been started.—— The Colville M. & S. Co. is pushing work on the Mountain Boy and Summit adits; the latter is intended to develop the vein at a depth of over 700 ft.——A contract has been let by the Silver Tip Consolidated M. & S. Co. to drive an adit 200 ft. long on its property on Iron mountain.

Republic, Jan. 2.

OKANOGAN COUNTY.

(Special Correspondence).—An electric locomotive has been placed in position in the long bore of the Palmer Mountain T. & P. Co. at Laomis; the mill is nearly completed.——The Nespelem Central Mining Co. has installed an electric fan and drilling machinery at its mine in the Colville Reservation. Ore recently found in the mine assayed about $51 per ton.——The Mareus D mine lately produced 20 tons of high-grade ore from the first level. The shaft is being sunk to a depth of 150 ft. A wagon road three miles long has been constructed from the mine to the Okanogan river.

Republic, Jan. 2.

CANADA.

BRITISH COLUMBIA.

The Grand Forks Smeltermen's Union No. 180 and Phoenix Miners' Union No. 8 arranged to resume work at the smelter and mines of the Granby Consolidated M. & S. Co. the day after Christmas; owing to the impossibility of immediately reorganizing the force, only 25 men were accepted on Dec. 26, 75 on the succeeding day, and in a short time over 800 men will probably be employed by the company. The scale of wages adopted is about 50c. per day lower than that prevailing when the mines closed on Nov. 11.——The output of the Rossland mines for the week ending Dec. 21 was as follows: Centre Star, 4652 tons; Le Roi, 2084; Evening Star, 30; total, 6766 tons.—— Since adding 10 stamps to the mill at the Queen mine, near Salmo, 55 men have been employed on that property.—— The Canadian Zinc Co. expects to have its electric zinc-reduction plant completed about Feb. 15; it will be the first of the kind on the continent.—— At the Stemwinder mine, in the Similkameen district, rich ore has been found on the 500-ft. level.——The Whitewater mill has reduced its consumption of ore to 280 tons daily.—— The ore shipments in the Cranbrook district for the week ending Dec. 28 were as follows: St. Eugene, 479 tons; Sullivan, 600; North Star, 64; total, 1143 tons.—— Ten men are working on the 225-ft. level of the Crescent mine at Skylark.—— The completion of the tramway at the Hewitt mine, near Slocan lake, is being hurried so that ore may be sent to the mill as soon as possible; it is intended to transport 100 tons per day.——At the Maggie mine a new lode containing 24 in. of clean galena has been found in sinking the shaft.—— In crosscutting the Reco-Goodenough lode a streak of ore 11 in. wide has been found, but it is of much lower grade than the ore formerly shipped from this property.—— At the Bluebird mine good galena ore 20 in. in width has been developed; a carload of it has been sacked for shipment.

The ore shipments from the Rossland mines for the week ending Dec. 28 were as follows: Centre Star, 2840 tons; Le Roi, 1680; Le Roi No. 2, 431; Evening Star, 37; Bluebird, 40; total, 5028 tons. At the Trail smelter there was received during the week ending Dec. 28, 4872 tons of ore. Besides that sent from the Rossland camp, shipments were received from other mines as follows: St. Eugene, 804 tons; Silver King, 11; Whitewater Deep, 21; Reco, 47; Vancouver, 21; Granite, 40; Hewitt, 21; La Plata, 165; Sunset, 21 tons. At the smelter of the Le Roi Mining Co. at Trail shipments were received as follows: Le Roi, 1680 tons; First Thought, 109; total, 1789 tons. The total shipments from the Rossland and Slocan-Kootenay districts during 1907 were 1,608,048 tons.

Special Correspondence.

Johannesburg, Transvaal.

Diamond Schemes that Went Wrong.—Exodus of White People.—Mineral Production.—Base Metal Mining.—The Industries Commission.—Future of the Country.

It looks as if some of the shady diamond propositions that have been organized to fleece a gullible public were "coming home to roost." The Ebenezer diamonds went through the winding up process the other day. The investigation committee appointed to examine into the doings of Beresford diamonds was not able to prove the allegation that the property had been salted. "Gross misrepresentation" seems to be the verdict of this jury. One crime is as bad as the other, and today this enterprise, whose shares reached a high figure, are practically worthless. But the worst impression has been made by Dr. Carstorphine's report on the Robert's Victor diamond mine. Dr. Carstorphine is an honest and able geologist, with wide South African experience, who was commissioned to make a thorough examination of this property, which was looked upon as a thoroughly sound proposition. His report is disconcerting. The original area of the mine was stated to be 102 claims. To be conservative, so it was stated, this estimate was cut down to 99 claims. Dr. Carstorphine's report shows that there must have been more "gross misrepresentation," for he gives the area of the mine as 57 claims. Robert's Victor shares, which were boomed up to £14, now stand at £2. Through this "gross misrepresentation" by the mine managers, much money must have been stolen. Of course the culprits should be in jail, but they are not. These fraudulent enterprises do an incalculable harm to legitimate mining, and do a great deal to keep capital, which is so needed for the development of South Africa, out of the country.

The exodus of white people from South Africa continues. In the past 21 months about 26,000 people have left the country. In a recent speech the Premier of the Transvaal, General Botha, declared that what the whole of South Africa wanted was a large white population. It is therefore rather distressing to know that instead of the whites increasing they are steadily leaving the country. Under the circumstances the best thing that a white man out of employment can do is to leave South Africa, if he has sufficient money. Little headway is being made in solving the problem of the unemployed. Many white men are working hard for the municipality at wages that can only be considered starvation. People are beginning to state that legislation must be introduced to protect the white man. No doubt this will be one of the recommendations of the commission now taking evidence in Johannesburg. What form their recommendation will take is difficult to say. Some people advise passing a law prohibiting the Kaffir from doing skilled labor on the mines, on the lines of the Chinese Labor Importation Ordinance, which distinctly protects the white man from the Chinaman.

The following particulars of minerals (other than gold, coal, and diamonds) produced in the Transvaal during the month of October, 1907, is of interest:

	Tons.	Value.
Copper ore	101	£3,250
Galena "	151	1,573
Tin "	66	1,980
Miscellaneous (asbestos, graphite, mercury, zinc blende, etc	103	1,488
Lime	2,322	4,576
Total value		£12,867

Compared with the returns for September (the value of the base metals having been declared at £19,966) the figures for October show a big drop. Almost all this decrease is accounted for by copper. There is no doubt that the high market values of the base metals stimulated the work of exploitation, but now that copper has had such a serious fall, and with it zinc and lead, the development of base metals will be seriously checked. In an expensive country like the Transvaal the prices of metals must be very favorable before people feel inclined to go in for copper, lead, and zinc.

Quite contradictory evidence is being given before the Industries Commission now sitting at Johannesburg. This commission has been appointed for the purpose of inquiring into the possible extension of industries in the Transvaal. The evidence given by the working men is a strong plea for protection, while the arguments presented by the Chamber of Mines is an uncompromising request for free trade. Self-interest seems to dictate the evidence so far given. From the workman's point of view, protection is required for the Transvaal, while the Chamber of Mines people will benefit most from free trade. It is to be hoped that a fair compromise will be effected, and that any industry with a chance of success in the Transvaal will be helped in every way. Year by year the gold reserves of the Rand are growing less, and statesmen fully realize that if the gold does not help to develop the country, the Transvaal in twenty-five or thirty years will be like a sucked orange.

London.

Coalite.—A Smokeless Fuel.—Conditions in England.—An Interesting Invention.—Wood Pulp and Mining in Newfoundland.—Tanganyika Concessions.—Important Copper Enterprises.

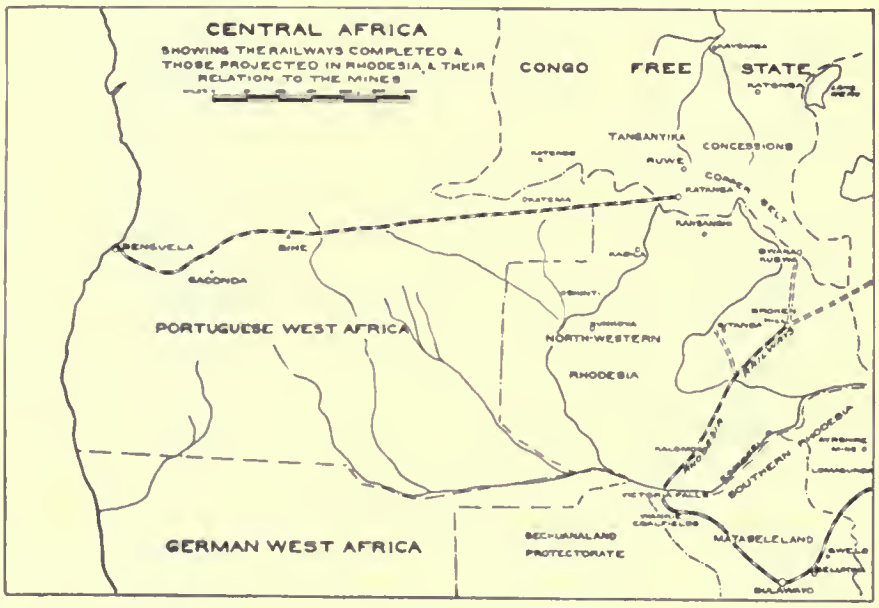
During the early part of 1907 a great deal was heard in London of the new fuel Coalite and in June the public was invited to subscribe for the capital of a company formed to manufacture and sell it, called British Coalite Limited. The shares were not taken up freely by the public, and the underwriters were saddled with considerable liability. At the time, the information published as to the nature of the fuel and the process employed was scanty, and such facts as became public were unofficial or were supplied by the opponents of the scheme. The patents describing the process have been published, one of them a month ago and the second this week; it is therefore opportune to say something about the subject at the present time. Briefly, the idea is to partially coke a bituminous coal, so that it will burn with a bright smokeless flame in an open grate. In England the closed stove and the steam or hot-air pipe are not popular, and though gas has to some extent displaced solid fuel in the cooking ovens, the open grate continues to be used for heating purposes. England is a country subject to mists and fogs, and when the air is still, the smoke from the chimneys hangs in a dark sulphurous cloud. In the manufacturing towns of the North of England most of the black fog is caused by the manufacturers' chimneys. In London there are very few works and factories, and such as do exist are forced by law to burn the best quality of South Wales smokeless coal. The London black fog is caused almost entirely by house-fires. It was the idea of the inventor and promoters of Coalite to appeal to the London householders and encourage them to use a fuel that was guaranteed to give no smoke and yet to burn perfectly freely in an open grate. As already mentioned, the details of the manufacture and the actual nature of the fuel were not disclosed, and the matter was wrapped in some mystery. There were many guesses published, and some articles appeared in the press written by coke and gas-makers, giving the

opinions of rivals as to the validity of the unpublished patents. It is not until the last month, when the two patents were published, that any reliable opinion could be given. The patentee is Thomas Parker, a well known engineer and electrician, and the patents are numbered 14365 and 17347 of 1906. Essentially the claim is for a hard and smokeless fuel produced from bituminous coal by a process of partial destructive distillation, the heat being gradually increased to a temperature of 800° F and maintained at this temperature until the illuminating gases cease to be evolved, after which steam is introduced for the purpose of removing the sulphur as much as possible and of reducing the temperature to some extent before discharging the retorts. The specifications give some details, but only of a meagre kind, as to the nature of the apparatus and plant, but these do not really matter, as the patent is for the fuel itself and for the method of the process, rather than the plant. The process also includes the working up of by-products, such as the illuminating gas and pitch.

The chief point of the process appears to be that the coke made is just hard enough for handling, and for use on a small fire, and will burn freely in an open grate without any draft. The low temperature used in coking causes sufficient bituminous matter to be retained and produces a texture soft enough to make the fuel burn easily. It is probable that the smokelessness is obtained as much by the swelling of the coal and the porosity of the fuel, so bringing a larger surface for contact with the air, as by the partial driving off of the bituminous matter.

Coalite does not differ greatly from the old metallurgical coke used a hundred years ago; this was soft and semi-bituminous, and was not made at very high temperatures. Modern metallurgical coke is made at high temperatures, so as to produce a fuel strong enough to bear the burden of large blast-furnaces, and the coke obtained as a by-product in gas manufacture is just as hard, because a high temperature is used for the purpose of obtaining a large quantity of illuminating gas from the fuel. The production of Coalite seems to me to be a reversion to the days before hard coke was invented. The inventor and the company certainly deserve success in founding a big industry in smokeless fuel, but it is difficult to say definitely that their patents are unassailable.

During the past few weeks some curious reports have been circulated in London with regard to the proposition of the Amalgamated Press Ltd. to use its reserve fund for the prosecution of mining ventures. This, of course, is a wild story. The Amalgamated Press is the company owning the Harmsworth publications, the *Daily Mail*, the *London Magazine*, and a whole host of weekly and monthly publications. The company is prosperous and pays good dividends. For some years the directors have foreseen the coming scarcity of wood pulp and the consequent rise in the price of paper, owing to the prodigal way in which the spruce fir is being used up. They therefore looked out for a tract of country for themselves where spruce can be grown on scientific principles and where paper could be made on the spot. Newfoundland was fixed on, and after exhaustive tests of the quality of paper made from the trees growing there and of the possibility of seeding and replanting trees, a large tract of country, covering over 2000 square miles, has been acquired. A new company called the Anglo-Newfoundland Development Co. was formed in order to exploit the forests and erect paper factories. It is proposed that other publishing companies shall join in the scheme and take part of the shares. The brothers Harmsworth also are taking shares personally. The Amalgamated Press is to use the reserve fund of the company in subscribing for capital in the Anglo-Newfoundland, as it is considered best to apply the fund in this way instead of investing in depreciated Government securities. Besides, the present is not a suitable time to ask the public to subscribe to new shares. Many of the preference shareholders in the Amalgamated Press objected to this use of the reserve fund, and stopped at nothing in opposing the scheme. Hence the rumors that the reserve fund was to be invested in wild-cat mining schemes. In most rumors there is generally a basis of truth, and this case was no exception. The facts are that in examining and developing the forest lands, traces of mineral outcrops were found, and with a view to turning every opportunity to account, the directors asked John Taylor & Sons to send a mining man to the spot to make an examination. Rowland Feilding went out accordingly and is directing development work. The deposit on which most work has been done contains mixed lead and zinc ores, and its commercial value is not yet fully ascertained. Within the last few weeks some copper outcrops outside the company's tract have been discovered and the land acquired. Newfoundland is somewhat of a neglected country, although mineral deposits are known to exist there.



The reports of the Consolidated African Copper Trust and of the Tanganyika Concessions have been published this week and give some information regarding the properties in Rhodesia about which a good deal has been heard during the last five years. It is a disappointment to find that the Tanganyika report contains no reference to R. J. Frecheville's recent visit. There is no mining engineer who is a better judge of a mine than Mr. Frecheville and people in London were keenly on the lookout for his opinion. It should be remembered, however, that he was not sent out by the company but by other people who were contemplating the investment of capital in the scheme, so the company has no say in the publication of his report. It is probable, however, that his opinion will become public property before long. Your readers may remember that the country owned by this company was explored and acquired by Robert Wil-

liams. In the early stages the reports were so glowing both as regards the extent and richness of the deposits that some of us were coldly critical. As time went on it was found that every mining man who visited the district came back considerably impressed. I have in my possession some specimens, and I have seen the bulk samples. The ore is massive chalcopyrite and pyrite mixed and contains about 6% copper, in many cases more. The report of the Consolidated African Copper Trust contains some interesting information as to the progress at the Edmundian mine. The ore deposit has been extensively opened up and veins 30 to 36 in. wide, assaying from 10 to 20% copper, have been proved over considerable distances. At one point the vein is 7 ft. wide with indications that it will prove a lenticular mass. Arrangements have just been completed for the building of reverberatory furnaces. The concentration of the ore is to be effected by the Elmore vacuum process, which is now coming forward in a most interesting way.

Butte, Montana.

Copper Production.—Smelter Rates Raised at East Helena.—Transfer of Control in the Stewart.—North Butte Affairs.

The estimated copper production in the Butte district during 1907 is 240,887,516 lb., as against 342,688,809 lb in 1906, a decrease of 101,801,293 lb. Each month of the past year showed a decrease from the corresponding month of the preceding year, but the big falling off came with the sudden decline in the price of copper and the rapid curtailment of production by the Amalgamated Copper Co., beginning in August. From a normal production of 30,000,000 lb. per month the yield fell to 7,000,000 or 8,000,000 lb., and during the last month the Amalgamated mines, with the exception of those of the Boston & Montana Co., were closed entirely, and so were the mines of the North Butte and Butte Coalition companies. The Clark mines reduced their production 50%, and the only company operating in the Butte district that produced more copper than it did in 1906 was the Pittsburg & Montana, a small concern with a daily output of about 150 tons of ore. The estimates of production for 1907 are as follows:

Company.	Pounds of copper.
Boston & Montana Co.	63,053,655
Anaconda	64,154,636
Butte & Boston	9,209,650
Washoe	6,438,420
Parrot	5,403,010
Trenton	6,794,475
North Butte	29,534,240
Butte Coalition	24,971,800
Original (Clark)	17,296,940
Pittsburg & Montana	4,785,090
East Butte	3,965,480
LaFrance	2,168,975
Miscellaneous	3,111,145
Total	240,887,516

Montana mining men, outside of the large companies, are up in arms against the action of the American Smelting & Refining Co. in raising smelter rates at the East Helena smelter. It is claimed that the new rates are "exorbitant and confiscatory." The new rates went into effect on December 1. A heavy penalty has been placed on silicious ores, and iron ores alone can be treated at a reasonable figure. Already a number of mines have been compelled to shut down because of the new rates, and others will probably have to suspend. The East Helena rates, following the shut-down of the Washoe plant at Anaconda, and the suspension of the independent smelters in Utah, competitors of the East Helena plant, is a hard blow to the mine operators. They claim that the new rates are an advance of fully 50%. Silicious ores that were treated at the Washoe smelter at a maximum charge of $7.50 per ton will cost from $15 to $22 at East Helena. Where the Washoe smelter paid for anything over 50c. in gold, the East Helena smelter will pay for nothing less than $2 in gold.

The North Butte has made a temporary arrangement with the Butte Reduction Works, owned by the Original Mining Co., a Clark company, and the latter will for a time treat some North Butte ore. The North Butte has therefore resumed mining in a small way and is shipping from 200 to 300 tons per day to the reduction works. For what period the arrangement has been made can not be ascertained, but the capacity of the plant is large enough to take care of the Clark production and the present production of the North Butte. However, the Original mine is closed for repairs and one report is that the reduction works will receive North Butte ore only until the Original resumes production. Still, the Clark mines have not been run to capacity for four or five months, the output being limited to about 40% of the normal, and until the normal condition is restored the smelter may be shared with North Butte.

The report comes from Wallace that F. A. Heinze has probably sold his interest in the Stewart mine to the Bunker Hill & Sullivan Co. The Stewart has been in litigation with the Cœur d'Alene Development Co., a concern closely allied with the Bunker Hill people, and engineers of the Bunker Hill Co. recently made an examination of the Stewart. Upon that came the announcement that the Stewart would resume operations in a few weeks, which is said to indicate a Bunker Hill ownership, as that company is operating its properties to capacity while the other producers are curtailing on account of the drop in the price of lead. The trouble with the Cœur d'Alene Development Co. appears to have been settled, for that company, on whose ground the Stewart mill is situated, has agreed to permit the Stewart to resume operations on the mill.

Wallace, Idaho.

Output of the Coeur d'Alene.—Dividends Increase.—Tonnage Produced.—Severe Effect of Lower Metal Prices.—Expectation of Recovery.—Future Prospects.

In spite of the decline in the metal markets and the shutting down of several of the large mines, dividends exceeding those of 1906 by $31,500 have been paid by the big producers of the district. The total amount paid is as follows:

	1906.	1907.
Bunker Hill & Sullivan	$2,340,000	$1,980,000
Federal M. & S. Co	2,040,000	1,710,000
Hercules (estimated)	720,000	1,052,000
Hecla	450,000	520,000
Snowstorm	90,000	360,000
Success	20,000	60,000
Monitor	.....	9,500
Total	$5,660,000	$5,691,500

Under the present owners the mines of the Cœur d'Alene have now paid in all $21,017,500 in dividends and under previous owners $11,501,307 making a grand total disbursed of $32,518,807. This is distributed among the different mines as follows.

	Paid under previous owners.	Paid under present owners.
Bunker Hill & Sullivan	.....	$9,846,000
Federal M. & S. Co	$8,488,307	6,310,000
Hercules	.....	2,772,000
Hecla	.....	1,520,000
Snowstorm	600,000	450,000
Frisco	1,723,000	.....
Pittsburg	90,000	.....
Monitor	.....	9,500
Success	600,000	80,000

The ore shipped from the district during 1907 is estimated at 343,125 tons, the maximum shipments being in

March (with 41,170 tons) and the minimum in December, when only 15,000 tons were produced. The total is practically the same as for last year. Throughout the whole of 1906 the mines were worked to full capacity and for the first few months of 1907, owing to the fact that the price of lead reached a higher figure than for 25 years past. Throughout January, February, March, and April the price of lead was six cents and the average price of lead throughout the whole year is only two-thirds of a cent below the average quotations for 1906. At these figures the crude value of the ore shipped from the Cœur d'Alene is roughly $20,000,000. Since 1900 the mines have shown a rapid increase of production with a

Map of Idaho.

corresponding increase of net earnings. In 1901 148,890 tons of crude ore and concentrate were shipped to the various smelters; in 1902 the shipments were 160,310 tons; for 1903, 200,596 tons; for 1904, 274,000 tons; for 1905, 316,000 tons; for 1906, 344,000 tons, and about the same for 1907.

Had it not been for the decline in the metal markets during the past few months of the present year the tonnage would have surpassed that of 1906, but the closing of the Morning mine at Mullan, the second biggest lead-producer in the district, the Snowstorm, the Success, and several smaller mines, has cut the production during the last month or two severely.

The value of the lead-silver ore and concentrate shipped to the smelters during 1907 was $64.95 per ton, while the Snowstorm copper ore averaged about $20 per ton, as sent direct from the mine without concentration. The total shipments will be about 344,000 tons, of which about 286,000 will be lead-silver ore and concentrate, the balance being copper ore from the Snowstorm, Monitor, and the smaller copper producers. The value of the lead shipments is roughly estimated at about $14,200,000 containing $4,250,000 worth of silver. The copper ore is valued at $1,000,000, containing silver and gold to the extent of $300,000, making a grand total shipped from the district of about $20,000,000.

The outlook for the present year is excellent and it is expected that several new mines will become productive. Among these there is every reason to believe that the Stanley, Rex, Surprise, Idora, Stewart, Pittsburg, Charles Dickens, Nabob, and Tamarack & Chesapeake will reach the dividend stage provided that the metal markets recover. With the completion of the Idaho Northern the output will be increased enormously by mines on the northern side of the district.

Salt Lake, Utah.

Mine Operators Organize.—Smelter Rates Raised.—The Smoke Litigation.—Lead Output Suffers.—New Concentrators at Garfield.—Shipments from Tintic.—Coal Production.

The mine owners of Utah will probably form an organization. Such a movement has been in contemplation, and since the late attempt of local smelting companies to raise their treatment charges with additional penalties, the movement has rapidly taken form. Utah producers have been confronted with some serious problems lately, but by thorough organization and promptness of action, they hope to overcome the evils that threaten to cut down their profits or force them out of business entirely, particularly the owners of the smaller mines. For some months the charge has been made that competition in the local smelting field was practically at an end. There seems to be a perfect working alliance between the American Smelting & Refining Co. and the United States Smelting, Refining & Mining Co. with respect to the making of new ore contracts or the renewal of old ones. Producers who had no contract, but who had been accustomed to entering the open market with their product, were informed that their ores were not wanted at any price, and several instances have come to light where the product has been unloaded from the cars and left at a convenient place near the sampling mills, in the hope that conditions would right themselves and the product become marketable. Other instances have been noted where the smelting companies have not only sought to exact higher charges and penalties, but have interposed a clause in contracts, which when operative would give them one-half the profit above a certain fixed basis. This was too much; and the result has been that very few contracts have been signed by the producers, opposition being almost unanimous.

This has led to an independent smelter movement; that is, many of the producers have subscribed to the project originally planned by F. Augustus Heinze. This smelter is now assured, the site has been secured, and it is expected that the breaking of ground will begin within ninety days. The new plant will be equipped with both lead and copper furnaces. In addition to this, the lead-silver ore producers of the Tintic district will find relief in the construction of the new smelter of the Tintic Smelting Co., which is now being constructed. This plant will be ready in April, and there is a probability of the plant of the Utah Smelting Co., at Ogden, being started up again right away. The Ogden smelter was shut-down several weeks ago after a run of three or four months. The company purchased ores when metal prices were high, and came to grief when the market collapsed.

The copper smelters at Murray and Bingham Junction, involved in the injunction from the Federal Court, are practically out of business. The plant of the Bingham Consolidated closed on the day following Christmas;

the fires were drawn from the last furnace of the Utah Consolidated on the night of the 4th inst., and the United States Smelting Co. has notified all shippers that no more consignments will be received at either of its Bingham Junction plants; that it is the intention to close them down. This company has about five weeks' supply of lead ore on hand, and about three weeks' supply of copper ore. The victory of the farmers is complete. The smelters have been declared a nuisance if erected within a farming community. The Garfield plant of the American Smelting & Refining Co., however, is not involved in this decree. The plants that have been compelled to move will be re-built in Tooele county, within 30 miles of Salt Lake City.

While production from Utah lead mines has been practically suspended for the time being, many of the copper mines are being operated. Notable among them is the Utah Copper and Boston Consolidated at Bingham and the Cactus mine in Beaver county. The Utah Apex, Utah Development, Utah Consolidated, and Ohio Copper, however, are on a development basis. Eight sections of the new mill of the Utah Copper Co. at Garfield, are now at work. The management reported a production of 3,000,000 lb. of copper in December. The mill of the Boston Consolidated at Garfield has been given a trying out and within the present week the first section will be in regular operation. Three sections of the plant are ready. The St. Joe Mining Co. has been placed in the hands of a receiver. It owns property at Bingham upon which little development has been performed in late years owing to litigation pending between the majority and minority interests.

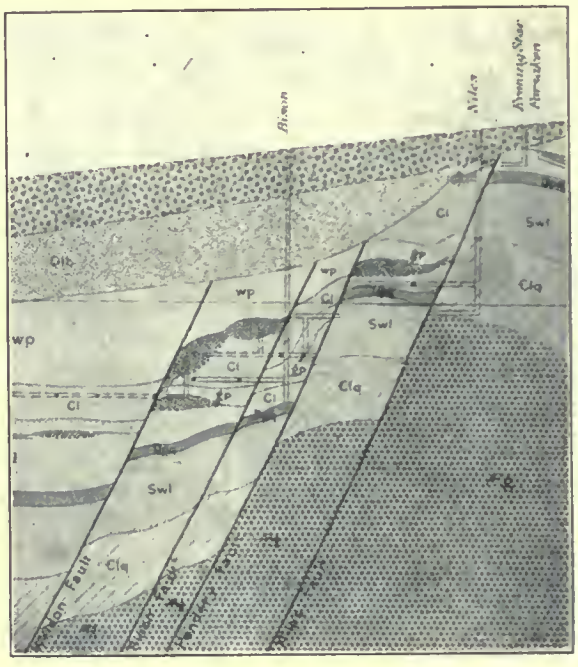
The ore shipments from the Tintic last week came from the following mines: Bullion Beck, 3; Beck Tunnel, 1; Colorado, 5; Centennial Eureka, 36; Eureka Hill, 5; Mammoth, 7; Scranton, 4; Tintic Iron, 10; Yankee Consolidated, 21 carloads. The annual report of the Coal Mine Inspector has been filed with the Governor and shows a production of 1,967,621 tons, or a gain of 128,432 over 1906. The output by counties is as follows: Carbon, 1,816,133; Summit, 73,918; San Pete, 4500; Emery, 2562; Morgan, 421; other small mines, 70,117 tons.

Denver, Colorado.

Gold Sovereign Directorate.—Land Frauds.—Production of Precious Metals.—Coal Output.—Mining at Leadville.

The dissatisfied stockholders of the Golden Sovereign Mining & Tunnel Co. got together at their annual meeting on Jan. 2 and ousted Abraham Rapp and his board of directors. O. H. Hinds, who led the opposition, was elected president and general manager, and an entirely new board of directors in sympathy with him was put in control. The stockholders also voted to rescind the recent acts of the Rapp management. This means that the lease granted to the Franklin Leasing Co. a few days ago will be cancelled and the three-year ore contract with the Golden Cycle mill at Colorado City will be reconsidered. It is the expressed intention of the present management to operate the mine on company account.——The Department of Justice, which has been prosecuting several cases of alleged frauds in connection with the coal-lands investigation, has received several adverse decisions recently in the Federal Court at Denver. Judge Lewis has given his decision that the present laws do not cover the case as taken up by the Government. He maintains that a man may promise to sell his allotment before he has received it without violating the law. This decision upholds the 'dummy entry' system. The cases will, of course, be carried to the higher court.

At the present time several estimates of the gold and silver production from Colorado for 1907 are current. Some of the estimators seem to be affected by the altitude. The preliminary report of the Director of the Mint credits Colorado with $20,888,833 gold and $7,687,796 silver. This ranks Colorado as the greatest gold-producing State and third in the production of silver. The falling off in the production of gold is $2,321,796. Whatever shortage does appear in the final figures may be attributed in large part to the burning of the Golden Cycle mill and the closing of several of the mines in the Cripple Creek district as a result. In general, the year has been free from labor disputes. The insufficient smelter capacity of the various plants and the recent financial disturbance may have had a slight effect. But one factor which must be recognized is the excessive operating costs due to high prices for labor and supplies. The rate of wages cannot be reduced without starving



Typical Leadville Geology.

the laborer, but with the present conditions only the high-grade propositions can be handled with profit unless they are of exceptional size.

Cripple Creek produced $13,074,992 in gold during the past year and would have materially increased this amount had there been adequate milling facilities throughout the year. The prospects for 1908 are very promising. The treatment and transportation charges are the most advantageous in the history of the camp. More than 40 new discoveries in old mines or prospects have been reported. Every property that has any indications of value is being opened and the camp has an abundance of skilled miners. There are now 12 mills operating in the camp. Most of them were started as experiments and have proved successful. These mills are estimated to have treated 113,675 tons during the year at a saving of about $600,000.——Since the closing of the mines in the down-town district of Leadville, most of the effort has been toward development and prospecting. The estimated production for 1907 is $10,906,128, which shows a loss of $692,590 from the figures given by the United States Geological Survey for 1906. A notable gain, however, was made in the value of the gold, copper, and manganese ores. The loss appears in the value of the silver, lead, zinc, and bismuth produced. The loss in the latter metals is due largely to the fall in prices.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

AN efficient pipe-wrench for pipes no larger than 6 in. diam. consists of a file, cold-chisel, and monkey-wrench. For large pipes take about 4 ft. of rope, fray both ends thin and put them together; commence with tip ends and wrap tightly around the pipe until a loop is made; then, with a piece of pipe or a round bar for a lever, turn the pipe as you would with a pipe-wrench.

BAILING WATER out of a shaft with the ordinary trap-bottomed bailing-bucket should never be done unless absolutely necessary, especially if there is soft or loose ground in the shaft that is not lagged tight. The unavoidable leakage washes all the loose material out from behind the lagging, loosens the blocking from behind the timbers, and causes loose ground to slab off.

IT IS NOT KNOWN that any attempt has been made to sink a shaft by using churn-drills to put down a series of holes which were subsequently filled with sand and then cleaned out sufficiently to permit blasting in successive sections. It would cost less to sink the shaft in the usual manner. One mining company bored a series of holes with a diamond-drill and shot them, but they had not been put down straight and the result was unsatisfactory.

IN the republic of Panama, the revised mining law requires all claim-measurements to be made on the slope of the ground, and not horizontally, which makes accurate mapping difficult, as the claim-lines swing in and out wherever the topography of the country is irregular. Placer claims are 5000 by 200 metres, containing about 2471 acres, and quartz claims may be made up each of three *pertenencias*, located end to end, each *pertenencia* being 600 by 240 metres, making an area of about 107 acres in each claim so located.

A HYPOTHETICAL MINE in California is opened on a 4-ft. vein of brittle quartz which has well-defined walls and dips at an angle of about 60° from the horizontal; the ore contains from 2 to 3% of sulphides and will probably average by assay $6 gold per ton. It is developed by tunnels. Timber is plentiful in the vicinity and water-power is available. A home company accustomed to California conditions would probably mine and mill the ore from this mine for $2.50 per ton; but it might cost a New York or foreign company $4 per ton.

A MINER may fence in his mining claim, if he wishes, and rent it for any lawful purpose, but the fact that it is used for agricultural purposes might militate against securing title to it as a mineral land, if any controversy should ever arise between a homestead claimant and the mineral claimant as to the character of the land and the purposes for which it was best adapted. The law does not contemplate the fencing in of mining claims, but there is no objection to it, and, as hereinbefore suggested, the question as to whether or not the mineral claimant should rent the land for agricultural purposes is one purely of policy and judgment.

SUCTION-PUMPS with rods inside the water-pipe cause a good deal of trouble when used in shafts, as all the working parts are hidden, making repairs difficult. If wood rods are used, they are apt to pull apart at the points where the metal joints are riveted to the rods. To repair such a break, it may be necessary to remove more than half of the water-column pipe, length by length, and when the break occurs some of the rivets almost invariably drop down into the valves. By the time the rod is repaired, the water may have risen over the valves, which are choked, and the bailing-bucket must be resorted to. Half-inch pipe makes better rods than the usual 2 by 2-in. wood strips.

BARITE has been mined for many years in various parts of Virginia. The deposits of commercial importance thus far developed which have been worked for barite alone, are lenticular masses or pockets in limestone or they occur superficially as loose lumps and nodules of irregular shapes and sizes, imbedded in the residual clays derived by the decomposition of the limestone. Minerals associated with the barite are limonite, sphalerite, galenite, pyrite, and occasional fluorite. The mining of barite in Virginia is surface-work; the greatest depth reached in any shaft is 160 ft. In southwestern Virginia the mining is largely by open-pit work; but in the district east of the Blue Ridge mountain there are vertical timbered shafts and drifts which follow the direction of the orebodies. The ore is washed, bleached, and ground, and occasionally jigged to remove impurities from the better grades of merchantable ore.

INSURANCE AGENCIES have had several inquiries from managers of mining companies who desire to take out a burglary insurance policy on the transportation of their bullion from the mine to the railroad station, against the acts of parties other than the carriers; but the mining companies refused to accept the policies that the insurance companies were willing to write, on account of a clause making them void in case the robbery was done by an employee of the mining company. In California and other Western States bullion is nearly always shipped through regular express companies; they take it at the value placed upon it by the shipper, charge for express-age according to this value and guarantee its safe arrival at the destination. If a mine is situated far from a railroad or important stage route, express companies may refuse to take charge of the bullion. In a case of this kind in Idaho the transportation of the bullion involved a 52-mile stage journey.

A SERIES of experiments for the preservation of mine timber planned in 1906 by the Philadelphia & Reading Coal & Iron Co. and the United States Forest Service resulted as follows: In the destruction of timber by decay, ventilation is a large factor. For wood-destroying organisms to exist, they must have air and water. It is the alternation of wet and dry conditions which produces rot. Seasoned timber is far more durable than green timber and is considerably stronger. From two to five months are necessary for proper seasoning. It may lose from 30 to 35% of its original weight. In durability peeled timber is superior to unpeeled timber; in the unpeeled condition the space between the bark and the wood favors the development of wood-destroying organisms. Timbers treated with creosote and a solution of zinc chloride have very effectively resisted decay. A good penetration of the wood by the preserving fluid from 2 to 5 in. has been easily secured. Timbers treated by the cylinder process are also standing well; but the success of the superficial brush treatment has yet to be proved. On account of their comparative cheapness and ease of application, requiring no plant, they may be of benefit to small operators or in a situation where the timber is likely to be broken. This series of experiments especially applies to the southern anthracite coal region; in places where conditions and species of timber differ, the results of these experiments may not be applicable.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Depth at Goldfield.

The Editor:

Sir—I notice that in your issue of December 28, Mr. E. G. Tinnebo asks why the mine operators of Goldfield have not proven, one way or the other, the vexed questions as to depths of commercial orebodies in this district, by means of diamond-drills. His letter ends with the question: "Do they fear the results obtained from greater depth?"

It is not necessary that I should enter a defense of the mining methods pursued here, or of the mines; but as Mr. Tinnebo's question has been frequently asked, and always through lack of knowledge of conditions prevailing here, it is time that a definite answer be made.

There have been, to my knowledge, five attempts to drill deep holes here, with core-drills of well known makes—all of them unsuccessful because of the soft and much broken country that must be penetrated. For example, a contract was taken six months ago by experienced drill-men to sink a hole 1000 ft. on a well known property in this district, just east of the present producing belt. At 210 ft., the drill entered soft clayey fault-material and, owing to an accident, the hole was lost. A second hole reached the same depth without much difficulty, but 50 days were consumed in sinking 35 ft. through the fault-material above referred to. This fills the hole rapidly whenever opportunity is given. At present, operations are suspended, casing having been used without success. The contract was taken at $5 per foot for the first 500 ft. The contractors have already lost money heavily and cannot possibly come out even.

Near this same hole, I am developing a property now opened to a depth of 250 ft. In the lower level there are exposed over 35 ft. of fault material which would be exceedingly difficult for a diamond or core-drill to negotiate. The country, being almost entirely made up of weak eruptives, presents many difficulties of the sort and is not at all favorable for economical drill work. This has been repeatedly demonstrated by very competent men in the business.

The question of depth in this district must, apparently, be determined by the slower process of shaft-sinking. Orebodies already exposed justify deeper development, and owners do not seem afraid.

ARNOLD BECKER.

Goldfield, December 30.

Cyanidation of Ore Containing Both Coarse and Fine Gold.

The Editor:

Sir—Regarding your question: "Given an ore containing some coarse gold, as well as gold finely divided, what steps would you take to save the coarse gold, which otherwise will escape solution in cyanide?"

Assuming that this ore does not contain any of the base metals in an amount to cause a high cyanide consumption, I would proceed to mill the ore in a weak cyanide solution (0.05 to 0.1%); passing over amalgamating plates; then classify by screening at practically 100 mesh; re-grind the oversize in tube-mills; again passing over amalgamating plates. After agitation, filter the slime, and precipitate the resulting solutions with a zinc method; zinc dust preferred.

WALTER L. REID.

Telluride, Colo., December 28.

The Editor:

Sir—Answering your inquiry, I would amalgamate first and cyanide the tailing, which is probably the obvious answer to be given, not knowing the peculiarities of the ore, or other conditions which might influence the treatment. For example, I know of an instance of a mine equipped with a mill and an extensive cyanide plant in operation which preferred to grind up some of the ore which contained coarse gold to pass a 40-mesh screen and ship to the smelter in preference to amalgamating and cyaniding. The determining factor was the richness of this ore, which contained between 20 and 30 oz. gold per ton.

E. P. KENNEDY.

Treadwell, Alaska, January 2.

The Editor:

Sir—In reply to your question:

"Given an ore containing some coarse gold, as well as gold finely divided, what steps would you take to save the coarse gold, which otherwise would escape solution in cyanide?"

There are several ways that suggest themselves to me, among which are the following four, given in their order of preference:

1. Crush to 40 mesh, amalgamate in battery and upon apron plates, slime the whole product in Lane mills, and agitate with cyanide solution.

2. Crush to 20 mesh, amalgamate in battery and upon apron plates, size, leach the sand with cyanide solution, and agitate the slime.

3. Crush to 40 mesh, amalgamate in battery and over plates, size, leach the sand, and agitate the slime, both with cyanide solutions, of course.

4. Crush to 20 mesh, size, leach the sand with cyanide solutions, and save the coarse gold on riffles placed in the discharge launders; agitate the slime with cyanide solution.

The matter of evolving the procedure under any one of these headings with the design of the necessary plant, can be perfected by any mining engineer or metallurgist, and need not be gone into at this time. In regard to the Lane mill, which I mention under heading No. 1, I can say that the foundry at Rapid City, S. D., manufactures what is called an improved Lane mill, in two sizes, and I can recommend it as an efficient fine grinder.

E. A. H. TAYS.

Denver, December 21.

The Editor:

Sir—The conditions described in your question probably obtain in the majority of gold mines, and certainly in all districts classed as free-milling; so that it would seem that the answer ought to be found in actual practice. With the same character of ore, approved practice will vary with local conditions, but roughly we may say that to save coarse gold we turn to amalgamation, for fine gold to cyaniding, for combined, alloyed, included, or otherwise rebellious gold, which even in a so-called free-milling ore, may amount to over 40% of the total value, to a variety of methods.

But the question is about the coarse gold. Are we confined to amalgamation, and if so, how shall we amalgamate?

Much of the coarse gold can be recovered by concentration, but the difficulty of sampling the concentrate makes this method objectionable unless the mine is doing its own smelting. Gold mines, however, are not apt to have their own smelters. Chlorination is apparently barred. We must amalgamate.

If the mine be in a district where there is an abund-

ance of water, especially if there is no tailing disposal problem, the answer comes from many a stamp-mill, from Gilpin county to the Mother Lode, from Ontario to Alaska, each with its own local inflection. Varying in equipment and practice; in stamps, mortars, screens, and plates; in drop, speed, feed-water, and plate-grade, as determined by local experience, yet essentially they are the same, and their deep chorus is retaining from 30 to 70% of the assay-value, including practically all of the coarse gold, in the mortars or on the apron plates.

I say practically "all of the coarse gold," for I do not believe that an appreciable portion of it can escape in a rusty condition from the mortars of a properly designed and operated battery. Such coarse gold as goes beyond the apron plates will almost inevitably be caught in the amalgam traps, on the vanners, or on other concentrators. If not, we are forced to the rather Celtic conclusion that it is not coarse gold.

Where water must be conserved, and, to some extent, even where the only difficulty is that the disposal of the tailing is restricted, the advice coming from the Black Hills, from the arid Southwest, and an ever increasing number of new districts is still to amalgamate for the coarse gold, but so long as the water must be separated, or recovered and pumped back, why not do the crushing in cyanide solution, for the cyanide is more efficient in the mortar than anywhere else.

Why does not South Africa join this chorus? That is another story. There the amalgamation recovery is so important that its efficiency must be the first consideration, and we must admit that a continuous feed of cyanide solution does not improve the character of amalgam or save mercury. Australia? Still another story, for here we have rebellious ore, much of it destined to roasting and grinding before final treatment. Really, when I started to answer the question it looked surprisingly elementary, but I find to cover it fully would really require a dissertation on the whole world's milling practice, so I shall have to let this suffice.

EDWIN C. HOLDEN.

New York, December 24.

Cyanidation in Nevada.

The Editor:

Sir—In your issue of Nov. 30, under the heading 'Cyanidation in Nevada,' R. Stuart Browne makes several statements in regard to the Goldfield ores, in which I think he is mistaken. In the first place Mr. Browne remarks that the ore is "a hard white quartz averaging about 85% silica, 7% pyrite, and about 8% lime, magnesia, etc." As a matter of fact, the ore is usually an altered and silicified dacite, with very little white quartz present. In the oxidized zone the silicification is especially strong, and the ore gradates from rock showing its original porphyritic structure to a dark brecciated quartz. In the sulphide zone the silicification is hardly so marked, but the ore is still essentially an altered dacite, in places changed to a dark flinty quartz, while in others the original structure of the rock is still plainly visible. Taking it as a whole, it forms a fairly hard tough rock, not easily reduced to a fine sand.

Mr. Browne also remarks that "tellurides of gold are frequently present." This is true only to a very limited extent. At the Mohawk, Great Bend, and several other mines, a little tellurium is present in the very high-grade ore, but in a great many cases the so-called telluride of gold is a form of tetrahedrite. Bismuthinite (bismuth sulphide) has also been mistaken for one of the telluride minerals in two or three cases. As a matter of fact, it is extremely doubtful whether any noticeable quantity of tellurium could be found in the ordinary low-grade ore of the camp of the grade mentioned by Mr. Browne (3 oz. gold). At the Combination mine during the three years that I was in charge of operations, a special look-out was kept for specimens of telluride minerals, but we were unable to find a single specimen in which the presence of tellurium was conclusively proved. I am, therefore, of the opinion that as far as the treatment of the milling grade of ore is concerned, with the possible exception of one or two of the mines in the Diamondfield area, the presence of tellurides need not be considered.

With such an ore as I have described, in which the gold is so finely disseminated, it seems to me very doubtful whether a good extraction could be obtained without comparatively fine grinding in addition to roasting. I am not sufficiently familiar with good roasting practice to form any idea of the probable cost of roasting Goldfield ores, but with coal at from $16 to $20 per ton, and crude oil at $2.70 per bbl. or thereabout, I am of the opinion that the cost of roasting the ore would exceed the additional cost of re-grinding to a finer state of division. During the seven months, from July 1, 1906, to February 1, 1907, the cost of re-grinding sand with a 4 by 16-ft. tube-mill of trunnion type, fitted with silex lining, was approximately 70 cents per ton of sand re-ground. This, I take it, is considerably less than the cost of roasting, with the best possible arrangement.

EDGAR A. COLLINS.

Tonopah, December 8.

Cyanide Practice at Copala.

The Editor:

Sir—In reply to the letter of Mr. D. G. Putnam in your issue of November 23, I would say:

(1) The methods of estimating cyanide and alkali mentioned in the article in question were not given by way of recommendation, but were intended to be merely explanatory, as indicating the basis on which the figures there given were obtained. It is taken for granted that every metallurgist will ascertain for himself the limitations of the methods he uses and their applicability to the individual conditions under which he works, because it seldom happens that any particular method of analysis is equally applicable under all circumstances.

(2) Mr. Putnam, in his letter, does not give the limitations of Green's ferro-cyanide method; he may see these by reading the paper published by Gerard Williams in the Journal of the Chemical, Metallurgical & Mining Society of South Africa for May 1904.

(3) Any suitable acid may be used in place of oxalic acid without affecting the procedure of the method in question. In cases, however, where too much solution is not made up at a time and where the acid burette is in constant use, oxalic will probably be found to maintain its standard as well as any other.

(4) Green has already pointed out the formation of zinc nitrate, acid to phenolphthalein; this nitrate, however, does not begin to form until the free cyanide has all been titrated and decomposition of the zinc-potassium cyanide commences, so that it would seem that Mr. Putnam's preliminary titration for free cyanide, in the instance detailed by him, was carried far beyond the real free-cyanide end-point, and probably to a point coincident with that which would have been indicated by the yellow end-point if using the potassium iodide indicator. The meaning of the term, 'first faint opalescence' seems to be the stumbling block. If Mr. Putnam wishes to know what we understand by it here let him first filter the solution to be tested for free cyanide until perfectly

clear and limpid, and place his measured quantity in a flask as transparently clean as the solution; then on adding the standard silver nitrate and observing the solution on a line with the eye against a dark background and with a good side-light, a faint general dulling of the brilliancy of the solution can be observed when the true free-cyanide has all been titrated. This is what we understand by the term, 'first faint opalescence.' Before this point is reached there may be sometimes a slight precipitate formed by the lime present, but this is easily distinguished with a little practice. If Mr. Putnam will test in this way to the true free-cyanide end-point and then add phenolphthalein and titrate with standard oxalic or sulphuric, or any other acid he may prefer, I think he will find that the protective alkalinity shown will agree closely with that indicated by Green's method.

I can assure Mr. Putnam that what he chooses to call the oxalic acid method does not necessarily "fail upon solutions which contain much K_2ZnCy_4" when properly performed, though I am not prepared to assert that it is universally applicable under different conditions; that is a point for each metallurgist to determine for himself.

L. N. B. BULLOCK.

Copala, Mexico, December 10.

[This is a good example of a useful discussion. Our readers will join us in thanking Messrs. Bullock and Putnam.—Editor.]

Capitalization of Rand Mines.

The Editor:

Sir—In your issue of December 21 my friend, Mr. Fischer Wilkinson, takes exception to my statement that, as a rule, the mines on the Rand are not over-capitalized, and says: "The nominal capital means very little."

It only means the thing that we are talking about, namely, the amount of capital placed upon a property by its sponsors and upon which the said property will pay adequate returns if the amount is not too great, that is, if it is not over-capitalized. He cites in refutation the price at which in many cases the working capital shares were subscribed, a point already alluded to in my first letter. But the working capital shares seldom exceed one-third and are sometimes less than that proportion of the total share capital, hence they are in the minority and cannot be regarded in any sense as the 'capitalization' of the company, unless the tail is to wag the dog. Their issuance at a premium is legitimate business, especially when guaranteed and underwritten by the issuing house, as already pointed out; in the cases cited an excellent return on the investment is being made even at the enhanced working capital price. For instance, in the case of the Witwatersrand Deep while the dividend is but 10% on the 80s. shares, it is 16% on the 50s. shares, or an average of 13%, quite good enough for a property with so long a life as it has. Moreover, this rate of dividends was established on monthly profits of £18,000 to £20,000, but the recent profits of £26,000 to £28,000 per month will admit of a decided increase in dividend over the 13% rate on working capital shares. The Robinson Central Deep, paying 17½% on working capital shares, is also good; hence admitting, for the sake of argument only, that the greater is to be measured in terms of the lesser, it is evident that the showing is still good. As for the Rand Mines Limited, comprising a group of 9 or 10 producing mines, and regarding which I am informed the dividend is to be increased, the 120% return may figure comparatively less on the *market* price, but that is a valuation which does not enter into the question of original capitalization in any manner, and was therefore purposely ignored by me.

With reference to the statistics quoted, these also I see are based on "market valuation of the shares," hence I fear they must be ruled out of order, with no necessity for quoting Disraeli on the subject of statistics. Finally, I must beg to submit, Mr. Editor, that your heading, 'Capitalization of Rand Mines' to my first letter, written in refutation of your editorial questioning the integrity of the Witwatersrand engineers, is something of a misnomer.

THOS. H. LEGGETT.

New York, December 31.

[The heading 'Capitalization of Rand Mines' seemed better than 'Integrity of Rand Engineers,' for the latter was a question that it was unpleasant and unprofitable to discuss further. Mr. Leggett holds that the engineers on the Rand are not responsible for any over-capitalization of mining companies and he denies that his professional acquaintances at Johannesburg participated in the flotations that made certain gentlemen at Hamburg and London so rich. We do not care to press the point. Mr. Leggett himself, Mr. H. H. Webb, and a few other first-rate men gave an example of professional decency, and it may be that they are generous enough to impute to others a standard as high as their own. Mr. Leggett says that he does not know of a single engineer who "gave his authority to over-capitalization and, indirectly, to the wild dealing in shares" during the boom of 1895 and at recurrent intervals. It may be that we are not agreed as to the definition of an engineer, and Mr. Leggett may refuse to recognize as fellow-professionals the men we had in mind. There never was a boom without such performances, and there never will be.—Editor.]

THE SAPPHIRE MINE IN MONTANA.—The sapphire mine at Yogo Gulch, Montana, is probably the greatest gem mine in the United States. The igneous dike which contains the sapphires has a length on the surface of about four miles; it probably descends to a great depth. It has been estimated that the entire content of workable sapphire-bearing rock may approximate 10,000,000 cu. yd. The stones obtained in mining this dike are not of large size. They range from 'culls' to gems averaging, when cut, from half a carat to two or three carats, and rarely five or six. The 'culls' are used for watch jewels and other mechanical purposes, for which they have an advantage over East Indian stones in their form; this is largely short prismatic or rhombohedral, with flat basal terminations. The gems are brilliant, free from flaws and range in color from light shades to the rich deep blue of oriental sapphires. They are sent to Amsterdam for cutting, and yield in finished stones from two-fifths to one-half of their original weight.

COPPER MINES OF ALASKA.—All the copper-producing mines of southeastern Alaska are on Prince of Wales island, in the Ketchikan district. The orebodies are genetically related to the intrusive rocks and occur either as contact or replacement deposits in the form of lenses or irregular masses. They are found in limestone, quartzite, or a greenstone-schist country rock. The chief copper ore is largely chalcopyrite, accompanied by pyrite, magnetite, and pyrrhotite, besides various gangue minerals. Enrichment zones are lacking, evidently on account of the absence of the zone of weathering which was removed during the glacial epoch; and at only one locality (Copper Mountain) are secondary ores present in quantity. At this place they extend only a few hundred feet below the surface.—Chas. W. Wright.

COLORADO.

Written for the MINING AND SCIENTIFIC PRESS
By FORBES RICKARD.

The end of 1907 finds Cripple Creek pre-eminent among the camps of this State, both in the record of production and in those steady improvements that give foundation for the production of the new year.

Cripple Creek production for the past year was close to $13,000,000. Dividends in excess of $2,000,000 have been paid out; in these the Portland, Vindicator, Mary McKinney, and El Paso mines have a good share of representation. The Cresson, South Dante, and Little Clara are among the mines that have come into recent prominence.

The drainage adit, still the most important piece of work affecting mining interests in common, got started in May on the 740 ft. of new 'backs' which it gets from the new portal. And while the advance has been delayed by the transfer of work from the hands of one contracting party to another, the adit has, mainly under the direction of the El Paso Co., been extended a distance of 1220 ft., out of a total of 26,000 ft. of this project. Driving is to be continued under new specifications.

The deeper development of several square miles of Cripple Creek's productive territory, to be accomplished through this adit, will coincide with a period in the history of the camp when milling and mining methods will have been brought near to the top notch of efficiency and improvement. It will bring within the range of profit and make available an immense area, much of which without such drainage would be out of reach of ordinary mining operations.

The end of this year sees the final stages of much litigation, which has been a hindrance to greater progress in the Cripple Creek district, notably the Portland and Stratton's Independence trespass suit. Signal advance has been made in the exploitation of the lower grades of ore from mines working under the lease system. The growth of the cyanide process, as shown by the erection of many new mills to treat the low-grade ores of mines and dumps, has contributed mainly to such a result. While the milling ore now ranges in value from $4 to $12 per ton, oxidized ores of an average value of $2.85 per ton have been successfully treated in the local mills. The successful exploiting of these low-grade ores must, in many instances, lead to discoveries of high-grade streaks, which under former mining conditions would have been overlooked. Particularly might that be the case where veins are blind and many of the dikes associated with the ore deposits do not come to the surface.

The Golden Cycle mill (750 tons daily capacity) of the company that bought the best part of the property of the United Gold Mines Co., was re-modeled, burned, and rebuilt during the year. After much adjusting of freight rates and treatment charges to meet varying competitive factors, the schedule shows an appreciable reduction in both transportation and metallurgical departments over the charges that have prevailed heretofore. Altogether, general conditions at Cripple Creek conspire toward the stimulating of the camp's production and an increasing activity in mine and mill.

While Cripple Creek has been receiving a stimulus from the advantage of the minting of its bullion production and meeting its payrolls with gold, Leadville has been operating under disadvantages of constantly falling metal prices and comes through the year with a showing that reflects the varied nature of its resources and does credit to the old camp. The slump in the prices of silver, lead, and spelter will for a time cut down the mining operations, through the closing of the Coronado and others of the mines in the down-town district, and some of the mines whose receipts and operating expenses have so near balanced as to make it a process of swapping dollars, yet Leadville has been equipped to make the most of the high zinc market that has prevailed through the greater part of the year and Lake county has been yielding 80% of the total zinc production of the State. During the year important discoveries have been reported from Leadville's gold belt, in the Breece Hill district. The Ibex group is employing from 400 to 500 men under lease and is getting high-grade ore from its 1300-ft. level.

The Yak Tunnel Co. has added to its already large development and has come through the year successfully. Its dividends will exceed the $320,000 mark of 1906. Of the production of the whole district, there has been heavy demand for silicious ores throughout the year. The monthly production has ranged from 71,000 to 77,000 tons, of which from 65 to 70% goes to the local smelters, from 8000 to 12,000 tons of zinc ore to outside points, and the balance to the Salida smelter. Among the newer enterprises that have come into prominence during 1907 are those of the Mammoth Co. in Big Evans gulch and the Bartlett Tunnel Co. on Sugar Loaf mountain. Rock Hill (in the Reindeer) has been the locus of new ore developments.

The mines of the San Juan have worked uninterruptedly and have maintained a good showing in 1907. In the Telluride district, a consolidation of small groups of mines was made through the Iona Gold Mining Co., and at Silverton a controlling interest in the stock of the Mountain Queen was reported sold to the Guggenheims. The Tomboy publishes the results of a most successful year.

In Gilpin and Clear Creek counties the progress of the Newhouse Tunnel claims first attention. It has this year drained the Saratoga and Old Town mines, through connections made with it, and incidentally disclosed new orebodies belonging to these properties. In March the adit had reached a length of 17,500 ft. and was then approaching the limit of its haulage capacity. The transfer and consolidation of the Six-Day and Perigo groups, near Rollinsville, was one of the interesting events of the year.

In metallurgical progress, two advances are noteworthy. The one is the introduction of the Huntington-Heberlein process in the Colorado plants of the American Smelting & Refining Co., making use of a partial roast preliminary to sintering before blast-furnace fusion. The object being to put the ore into condition admitting of lower temperature in the fusion; at the same time preventing lead loss and allowing of the utilization of a heavier proportion of sulphide in the smelting mixture. The other is the almost complete supercceding of the chlorination processes by cyanidation, and its accessory machinery and equipment, in the metallurgical practice applying to Cripple Creek ores.

In general, the mineral output of the State has been scarcely affected by the drop in the price of copper, since the production of this metal is, with small exception, accessory to the production of ores in which gold, silver, and lead predominate. The shortage of labor in the earlier part of the year did much more to limit the annual production than the lower metal prices of the last part of 1907. Cripple Creek especially experienced a drain upon its labor through circumstance of higher wages obtainable in the boom camps of Nevada. The exodus resulting has been checked in the latter months of the year and since the Goldfield troubles began there is promise of a gradual return of the Colorado miner to his former habitat.

Nagybanya, Hungary.

Written for the MINING AND SCIENTIFIC PRESS
By EDWARD SKEWES.

This district is in the eastern part of Hungary, bounded on the east by Roumania and Galicia. It is easily accessible, being about 13 hours railway journey from Budapest.

The principal mines are owned by the Hungarian Government, and the managers in charge may, in addition to their other titles, write Royal Hungarian Engineer. Some of these mines are very old. I was told that the Kereszthegyi, known hereafter as the Cross mine, had completed its one-thousandth birthday. On July 6 the Veresvizi, or the Red Water mine, celebrated its 500th birthday; all work in the mine was suspended, the mouth of the adit was gaily decorated with arches, evergreens, bunting, flags, and miners' lanterns; the interior of the machine-shop was like a conservatory. The Government distributed 2,500 litres of wine to the 540 employees.

The mines are among a series of hills related to the main range of the Balkans; they are situated at elevations varying from 400 to 800 metres. The country is well wooded, oak and birch being abundant. The formations are classed as trachyte and andesite, while the best mines are in quartz-trachyte, the eruptives breaking through the late Tertiary sedimentary rocks. The best mines are in a straight line from east to west, 20 km. in length, from Rota-Anna or Kapnik Banya to Nagybanya. Two kilometres farther west are the Borpatak mines, which have become famous within the last four years; the largest owner, formerly a Roumanian school-teacher, earning 18 kronen, or $3.50 per week, is now wealthy. Still farther west is Lapos Banya* which, prior to the fall in silver 20 years ago, was a hive of industry, as witnessed by several disused mills and smelters. In passing the site of an old copper smelter at this place I saw several men and women at work, and was told that they were milling all the slag, digging around all foundations, and milling the scraps for silver and gold.

The course of the veins is approximately north and south, usually five degrees more to the west of north than to the east of north; the dip may be both east and west in the same mine. At Felsobanya a good instance may be seen of the fan-like structure of the veins. The dip does not influence the productiveness of the veins.

The veins that I saw outside the main belt were narrow, none of them three feet wide, but were unmistakably veins continuous in length and depth, with well defined walls; they were as distinguishable as are the saddle reefs of Bendigo, there is no mistaking them. In several of the old narrow and crooked adits, I saw the results of using heat (of burning brush) to break the rock before the advent of explosives; such adits were unusually high and showed conchoidal fracture.

Through the courtesy of Mr. Bertalan I was permitted to go underground at the Cross mine. After walking 1,081 m. we came to a place where a large station had been cut, and where a vertical shaft had been sunk 380 m.; the bottom level had been driven at a depth of 332 m. At the station there are three large boilers, with electric hoists on both sides of the shaft; also large ore-bins, machine-shops, etc. The two drifts that I examined had been extended over 1,000 m. from the shaft, and the ventilation was good, save at the face, where it was unpleasantly warm for working, the men being almost naked, except for shoes and overalls, and in some cases even less. The veins are narrow when unproductive, but range from 2 to 5 m. in all the stopes, for where the veins are valuable they are always wide. The faces of levels were fully 2 m. wide. The cost of a drift on the vein, 2 m. wide and 2½ m. high, is 115 crowns* per metre; raises cost 80 crowns; and shafts 510 crowns. The vein is hard, principally quartz and sulphides. The height to the surface from the shaft was 300 metres.

The first 600 m. of the adit was built of, and arched with, stone, as were most of the levels where stoping was in progress. Instead of stull-timbers, old rails from 40 to 50 lb. were used, placed one metre apart, and covered with hard flagstone. From the ore-bins at the shaft to the mill the ore was conveyed in one-ton cars — long and narrow — hauled by one horse, drawing three cars, and pushing one car, by means of extended shaft, attached to the pushed car with an iron loop.

In 1896 a pamphlet was published giving a history of the mine; two or three extracts will be interesting. There is no record of the mine prior to 1086; in that year the Kuns (not the Huns) came and destroyed this mine with others in the district, and killed all the people in Nagybanya. In 1141 King Geiza II introduced the Saxons in large numbers to work the mine, and it was again in full blast. In 1490, while Columbus was dreaming of America, Prince Albert, a Polish prince, and brother of Ulaszlo II, the Hungarian king, burned the buildings, and work was abandoned. In 1710 the mine was again idle, on account of the miners suffering from an outbreak of boils and sores on the arms. About this time the Government officials resolved not to lease the mine, but to work it themselves, as it appears that every set of lessees left the mine in a pretty sickly condition. The tables from 1875 to 1895 are very full for every year. The figures are given in forints,† equal to 40 cents American.

TABLE I.

Year.	Income.	Expenses.	Net profit.	
	Forints.	Forints	Forints.	Dollars.
1875	232,396	176,722	55,674	22,269
1880	253,700	233,813	19,887	7,955
1885	301,783	185,414	116,369	46,547
1890	263,809	161,305	102,804	41,001
1895	285,913	177,941	107,972	43,191
1906	613,716	314,728	298,988	119,598

Another table shows full particulars of expense account, but only two or three items will be selected out of the 25 given.

TABLE II.

Year.	Tonnage.	Duty per stamp.		Concentrate.		Total value of ore.
		Kg.	Lb.	Tons.	¢	Forints.
1875	5,971	308	677	303	5.68	11
1880	7,160	323	700	349	4.87	10
1885	8,463	283	622	510	6.02	14
1890	8,224	332	730	645	7.85	16
1895	7,592	306	673	721	9.51	20

TABLE III.

Year.	Number of miners	All other employees.	Mill-ore.	Smelting ore.	Cost of stoping.	Office expenses, taxes, etc.	Total cost of stoping 1 cu. m.
			Tons.	Tons.	Forints.	Forints.	Forints.
1875	105	110	9,082	662	78.109	21.829	20.15
1880	76	189	8,590	1,126	46.341	24.423	17.23
1885	85	138	102	637	700.28	14.090	12.90
1890	83	132	94	361	594.95	17.859	15.66
1895	74	121	84	771	594.87	28.760	16.17

From Table II the duty per stamp (680 lb.) will appear ridiculously small, but the weight of the stamp is only 200 kg., the reasons for which will be given later.

The adit has a single track. Around the mouth of it there are no dumps; while the offices, machine-shops,

*Banya means mine; nagy means big; lapos, flat; felso, upper.

*A crown or krona is equal to 20 cents American.

†A forint is an old Hungarian coin, formerly equivalent to an English florin. It has not been coined since 1890.

magazines, warehouses, are near, all the waste rock must be conveyed some distance. The Cross mill was built close to the mouth of the adit. The building is long and narrow, and only one story. I have not seen a mill in Hungary built on a hillside. In the mill there are four sets of three batteries of Californian stamps, hand-fed, with no rock-breakers. In front of each set of batteries there are Rittinger (who was a Hungarian) amalgamators, about 2 ft. diam., which save from 6 to 8% of the valuable metals. No copper plates are used in the mills. The sand and slime are elevated by pumps to large spitzkasten, and the sand is concentrated on Rittinger tables, which were well regulated and were doing good work. The slime was treated on Bartsch revolving tables. (See Fig. 2.) From what I saw of the working of the Government mills, they appeared to be efficient, equal to the average of mills in other countries treating the same character of ore, containing galena, blende, antimony, iron pyrite, and quartz. The miners were expected to pick out the galena and blende when massive; this is sent to the smelters. The reason why the light stamps are used, is to prevent sliming; the principal portion of the gold and silver is in the galena and blende, and these minerals easily slime under a heavy blow and float on the water. An English company a few years ago, after spending 4,000,000 crowns in the erection of heavy stamps and up-to-date methods, was glad to sell its property for 350,000 kronen.

I omitted to mention that before entering the adit I was requested to put on a Government cap, a short coat with epaulets, brass buttons with hammer and pick embossed, similar to the crest of the A. I. M. E., also trousers, and there seemed to be a plentiful supply of such suits in stock for visitors.

The quartz trachyte in which this mine is situated is covered with andesitic tufa. There are many veins on the property. The reserves are estimated to last for 30 years at the present rate of production.

The Veresvizi, or Red Water mine, is named after the color of the water which flows from it. The present names of the claims which comprise this mine were given in 1764, and were not called after the discoverer's 'best girl,' as in the Western States, but were all named after the saints, as follows: St. Lipot, St. Josef, St. Haromsag, St. Marton, St. Ferenoz, St. Janos, etc. In 1775 the city of Nagybanya leased the mine to a private company until 1778, and in that year 472 lengths—as far as a man could stretch with his arms extended—were driven. The lessees, according to the records, did not keep up their development work. In 1795 the Government took possession and began to drive an adit. This adit is 11 km. long, with a height of 190 m. to surface. A shaft has been sunk 50 m. below. Fig. 1 shows the entrance of the adit. On this property there are 30 gold and silver-bearing veins, varying from 1 to 20 m. wide. The ore is in shoots, directly above each other, as shown in the sketch.

Through the kindness of Mr. Schmidt, the engineer of the Red Water, I accompanied him to an upper adit (Lobanya) which is 270 m. higher and 1 km. distant from the portal of the Svaiczer, or main adit. This adit must have been driven, at least part of its 800 m. in length, by the Romans many centuries ago. Here there was a waste heap, but a waste heap beautified by a variety of flowers growing in tastefully arranged beds, although in the midst of a large forest and a mile from civilization. In the adit there is a stope that serves as a vault or strong room; from it 150,000 or 200,000 crowns may be taken out at any time, if the mine requires it to meet any extra expenditure. It is not the Australian nest egg, in the shape of bullion, for the money is in the ore; the stope is 26 m. long, and from 1 to 5 m. wide. At one time 400 kg. yielded 13 kg. of gold. This ore is all sacked in the stope and the bags well sewn and passed from hand to hand to the adit. The vein was originally quartz, now it is rhodocrosite, with blende carrying silver and gold, next comes gray quartz with fine-grained galena, then a little calcite on the foot-wall, with small vugs or crevices in the richer portions. The miners employed in this stope are of the best selected brand, and are paid at the rate of 200 crowns, or $40, per month, together with a small percentage, from 3 to 4%, of the profits. There are two heavy iron gates in the adit. The miners work from 5 A. M. to 1 P. M., from 1 to 9 P. M., and from 9 to 5 A. M.

In connection with this mine there are three mills at work, all built on the level, and all using the same water as motive power and for milling, all lit by electricity, and in one, oil engines are at work. The mills are fairly close to the adit, the farthest not much more than a mile. The cars are of the same size and shape as at the Cross mine, and when drawn by horses four cars are moved; with locomotives, a train of 16 cars is pulled. The gauge is about 20 inches. This company has three locomotives. The horse-drivers used to stop at certain places and fill a small tank situated above the wheels on the side of the car; the water gradually fell on the rail through a small pipe.

In these mills the same methods are used as in the Cross mill. In the central plant a battery is employed exclusively for making tests. The smelting ore is also brought here, dumped from the sacks, and is crushed dry under Cornish stamps to the size of peas, sampled, re-sacked, and sent to the Government smelters. These three mills are well equipped with Californian and Cornish stamps, with Rittinger tables, concentrators, and slime-tables. They are well managed. The shipping ore carries about 130.80 in gold and 48 crowns in silver, or a total of $35.76 per ton. The mill-ore yields 21 crowns in gold and 1.30 crowns in silver, or about $4.50 per ton. The reserves in this mine are estimated at 22 years.

In the Felsobanya mill there are 75 stamps of 200 kg. each, and 72 wooden stamps weighing from 100 to 110 kg., and the mill treats from 30,000 to 33,000 tons per year. The cost of milling is 4 crowns (80 cents) and for mining, including all charges, from 8 to 12 crowns per ton.

Table No. IV shows the output, but in gold and silver only, together with the expenses of the Government mines in the Nagybanya district.

Table No. V gives the increase or decrease in the movable stocks during the year, also the profit and loss on the respective mines, together with the valuations; the last column is supposed to include everything that cannot be sold. These six mines are valued at 13,382,498 crowns, or $2,676,498; they made a profit of $75,518, or less than 3%. In ordinary mining, that is, with private funds, the interest would be considered low. The Hungarian Government mines, we are told, are not worked primarily for the profit, but for the benefit of the miners, and the towns near which the mines are situated.

Considerable improvement may be effected in the mines and mills owned by private companies or individuals. In one mine there were four persons employed pumping water by hand-pumps from a depth of 60 ft., in relays of about 12 to 18 ft., while there were only two miners at work stoping, but I have recently learned that there is to be a new management and that a steam-pump has been substituted. In connection with this mine there were nine stamps, 120 kg. each, which crushed three tons each per month.

The private mills, and there are many of them from Felsobanya to Nagybanya and from Nagybanya to Borpotak and from Umazzi to Lapos Banya, are very crude and primitive, all driven by water-power, with oak axles, cams, stems, and tappets (there are no rock breakers or feeders, even in the Government mills). The only machine is the Hungarian concentrator—a very remote ancestor to the bumping table of Gilpin county, Colorado,—which is a table 5 ft. wide, 9 ft. long, suspended by movable chains at each corner. The sides are six inches high. Motion is imparted by means of an extended arm under the head of the table, working in connection with a wooden axle and tappet, the blows varying from 1 to 3 per minute, and the distance of throw from 6 to 12 in. I saw over 60 of these at work, in more than a dozen different mills, but not one was being looked after as it seems to me it should have been. A small boy or girl fed the concentrator, and when the tailing end wanted raising a lever was put in a roller from which the end chains were hung and raised one notch. When the concentrator is full it is stopped, the tailing is thrown in the creek, the middling and heading to their respective departments for further treatment. The capacity would be less than 1½ tons per day.

This concentrator may have been suitable for the oxidized ores of 1,000 years ago, when the axle, cam, and tongue were new and in good order, but for the present ore it is not suitable, as it cannot possibly save more than 60%. In talking to the mill-owners, they said in effect —although I had to listen for hours: "My father worked the mine and mill in this way, and he handed it to me, and I must hand it over to my boy. We have not the money to erect new machines to save the slime, and if we did we should perhaps work too fast; we know we are losing 50% of the metals." In all the old mining leases the Government was entitled to all the mineral below 200 ft. in depth, consequently, for the sake of posterity, the mine must not be worked at express rate.

The free gold, here known as 'fire gold,' is extracted by a system of panning and then amalgamated. From a 20-stamp mill about 25 kg. of No. 1, or best concentrate, and about 35 kg. of the second concentrate, largely galena and iron pyrite, are sold monthly to the Government smelters. The pulp flows into strips, and the heading is carried to long narrow buddles having 45° incline; one boy attends to one buddle, and after feeding he cuts the block into small pieces with a wooden knife, so as to let the water pass uniformly. When the waste has been washed away a wooden trough is placed at the bottom of the buddle and the mineral is washed into it. These are panned and sometimes yield 'fire' or free gold. The toe of the pan is inclined on the principle of the vanning shovel. The pan is made of ¼-in maple wood, in some cases lined with tin; the sides and end rise 1½ inches. The operator, usually the manager or proprietor, takes the pan and strikes the back of it against a padded apron tied around his waist with a 3-in. throw, causing the heavy mineral to come to the back of the pan while the lighter particles are driven to the front, then a large bullock's horn, with a small hole at the small end, is held in the right hand and the lighter portion of the ore is washed into the tank; there is more shaking and more shaking, and more washing and more washing, until only a small portion of the richest is left; this is washed into a kettle, the contents of which are finally amalgamated. In the Government mill there were two horns for washing the pan; one had a very fine hole, used only during the final washing of the pan. In one large mill, where richer ore was being treated, there were four men constantly panning, with a responsible man supervising them.

The Hungarian cart is very primitive. It is drawn by two horses or oxen. The horses have but little head-gear. The body of the wagon has an inside measurement of 7 ft. 7 in. long, 1 ft. 9 in. wide, and 12 in. deep, say, one ton capacity. (Almost everything here is measured by dimensions, not by weight.) The body is secured to the carriage by means of a chain encompassing it in the centre, tightened by a long pole, the end of which is fastened to the rear. To unload is to unloosen the pole, remove the chain, and push the box over or shovel the ore out. For the carrying of concentrate a large basket with sloping sides and ends is placed on the four wheels, kept in position by upright poles connected to the axles by means of an iron loop, and lined with sacks. The wheels are 3 ft. diam. with 2-in. tires.

The Hungarian car was also crude, yet it meets the requirements of the narrow and crooked adits and levels better than the ordinary wheelbarrow. The width of the car is 10 in. There are no openings or doors, it must be lifted perpendicularly by the handles to be dumped. The central wheels are attached to the car by means of an iron strap. Both sets of wheels are underneath, the outside measurement being 6 in., so that they can easily be navigated over 8-in. plank by very small boys.

From what I saw of the Government officials at Nagybanya and Budapest, I feel confident that no foreigner need lose money without having a fighting chance, provided he consult the right men. I had occasion to compare some maps of mining leases with those of the Government records. The leases are in circles equal to 2,500 ft. diam., and these leases may be covered by a dozen other leases provided the centre of the prior lease is unmolested. The way the circles overlap each other resembles the overlapping of rectangular claims in a new mining camp in the West. In a private letter I wrote that "mining leases in Hungary are a delusion and a snare." The seller is usually careful to mark only his own circle on the map. A mining lease gives one the right to search for mineral in that particular lease. When mineral is found, the prospector takes a sample to the mining captain, the mining captain goes over the ground, compares the samples with the discovery, and if he thinks there is a 'mineral find' a notice is posted at the 'discovery point' to the effect that the prospector has applied for a 'mine' and that owners of adjoining circles must object or vacate all their rights in a rectangular block, 224 metres wide by 874 metres long, within a period of two months. This claim, when granted, is known as a 'mine,' and is unassailable while the yearly stipulated work is performed and the eight kronen are paid annually.

Geza Szellemy, the chief of the Government office of record, showed me a map where six circles covered the same territory. He also told me that in one case the Government received the eight crowns for the same area from nearly 20 different owners. I have since been informed that the owner or owners of a mine, by following their payable mineral under a lease, may apply for a mine to the exclusion of the owner or owners of the leases.

There are no private assay-offices, as Government laboratories are found in all the towns. The cost of assaying for silver is 70 hellers, about 15 cents, whereas if you want to know the gold in the silver, it costs eight additional crowns, or about $1.50. It did seem singular that a large sample could be pulverized, mixed with the necessary fluxes, scorified and cupelled for 15 cents, yet to part the gold and silver costs $1.50. The Government makes no reduction in price for a large number of samples, and the money must be paid beforehand; there are no exceptions to this rule.

Some of the younger members of the Department

would like to modernize the methods and make them more efficient; but in old countries there is a power with which you are unacquainted in the States, namely, Tradition, who will not die, neither can any David "hit him hard" in a vulnerable part.

Charcoal is used exclusively for fuel. Most of the labor in the assay department is skilled but not trained or technical. The Hungarians are quick to learn, and mix and handle the fluxes, scorifiers, and cupels well. The head of the Department does the weighing on the fine balances, and no more, save on special occasions. The Government will only purchase the ores or concentrates on scorifier assays, although they are low-grade, and the method is much more expensive than crucible assays, as large quantities of test lead are used in the former, which the Government must buy, whereas the Government makes its own litharge suitable for the latter method.

I took my samples to two different assay offices to check them, and the results agreed well. The assayers concede the fact that they are always low, and it is for a purpose, as the Government is a buyer. I took two of my check samples to Benedict Kitto, in London, and his results were 2% higher on 19 dwt. gold and 2 oz. silver.

At Fernezely there is a Government smelter which has been undergoing reformation for several months, so that several new reverberatory furnaces will be at work shortly. It was interesting in one of the old lead furnaces to see the Siberian hearth at work. The blast-furnace house, which is now idle, looks, with its 12 massive circular pillars on a side, like a nave of a cathedral. This house was built in 1853. Heap-roasting of matte is still carried on. Heretofore this furnace has had a capacity of 8,000 tons of concentrate per year.

A private company under the management of Henrick Auer, a well known chemist, is building a sulphuric acid works, the Government allowing the use of the sulphur from the smelter and giving a sum of money. Budapest and other towns will be available as markets. From Felsobanya station carloads of sulphur concentrate, also iron pyrite in lumps, are sent to Budapest to the sulphuric acid plants.

A prospectus, published in 1902, states that the wages of the miners is 1 crown per day; the wages today (apart from the Government mines) is about 50 cents per day, mechanics getting $1. The boys in the mines were earning from 10 to 15 cents and the boys and girls in the mills from three to five cents per day. The miners in the Government mines earn from 30 to 40 cents. These mines give steady employment, and a pension provided there has been good conduct. The only time there has been any labor trouble was during the spring of this year, when the miners in the Government mines asked for more wages, and I was informed the question was settled by a compromise after three weeks.

Beach wood for fuel costs 75 cents per cubic metre. No. 1 dynamite costs $7.50 per case of 50 lb., and detonators, $3.75 per 1,000.

The question arises: How does the management of the Government mines compare with that of the private properties? As a rule it is superior, but still one must confess that the standard of management of the former is not to be compared with the management of mines in the United States, Canada, or England. The private mines can call to their assistance the services of the Government engineers, through the Minister of Mines, without paying the consultation fees.

I think that Hungary holds out fair opportunities for successful mining in its gold and silver deposits, not to mention those containing zinc, copper, and antimony, besides the placers. The aid of the Government officials should be sought, and although they move slowly, they live. I have no doubt that a manager combining the enthusiasm of a "two year old" with the experience of a Methuselah, could galvanize the life of the department, and if so, success would be attained. The climate is good; the summer is hot; the winter is cold with plenty of sleighing. Labor is good, but saint-days are plentiful. I was told that in the Hungarian calendar there are 27 holidays, while in the Roumanian there are 37 days, all of which are religiously kept by the miners.

The ignorance of the language is not only a serious handicap but it is a tedious and vexatious worry, for it necessitates sitting or standing for an hour in order to ascertain through interpreters one simple question. A mining man, to do business here, should be able to talk Hungarian and Roumanian. All of the Government officials can converse in German.

AN ELECTRICAL HOISTING EQUIPMENT of considerable interest was recently built by the General Electric Co. for the Kendall Gold Mining Co., of Kendall, Mont. This equipment is designed to raise 2,000 lb. of ore from a depth of 1,000 ft. every 103 seconds when operating two drums, and every 170 seconds when only one drum is in operation. The shaft has two compartments and is vertical. Two cylindrical drums are used, provided with the usual clutches for individual and combined operation. The rope is 1 in. diam. and weighs 1.6 lb. per ft., the hoisting speed being 1,000 ft. per min. The feature of special interest about the equipment is one which was provided to overcome the effect on the somewhat limited generating plant from large rushes of current at starting, which tended to produce undesirable voltage fluctuations in the system. A fly-wheel, motor-generator set is provided, which consists of an induction motor and a direct-current generator with a heavy solid-cast fly-wheel swung between them, and a direct current exciter overhung at one end of the set. The system of control is arranged to brake the lode electrically in a manner which gives complete control over the retardation of the moving parts of the hoist, at the same time returning a considerable portion of their kinetic energy to the fly-wheel. The hoist equipment consists of a shunt-wound direct-current motor driving the drums by gearing, and receiving its power from the motor-generator set previously described. The small overhung exciter on the motor-generator shaft excites the fields of the direct-current generator and of the hoisting motor. The fly-wheel weighs about 12,000 lb. and operates at a peripheral speed of about 18,000 ft. per min. In order to obtain the value of the fly-wheel in alternately storing and surrendering energy, the induction motor is arranged for variable-speed operation, changes in speed being automatically controlled by the variation of the main-line current, which is led through a small three-phase regulating motor operating a water rheostat in series with the secondary winding of the motor.

MAN is the crowning work of God on earth, but though so nobly endowed, we must not forget that we are the lofty children of a race whose lowest forms lie prostrate within the water, having no higher aspirations than the desire for food; and we cannot understand the possible degredation and moral wretchedness ot Man, without knowing that his physical nature is rooted in all the material characteristics that belong to his type and link him even with the fish. The moral and intellectual gifts that distinguish him from them are his to use or to abuse; he may, if he will, abjure his better nature and be Vertebrate more than Man. He may sink as low as the lowest of his type, or he may rise to a spiritual height that will make that which distinguishes him from the rest far more the controlling element of his being than that which unites him with them.—Agassiz.

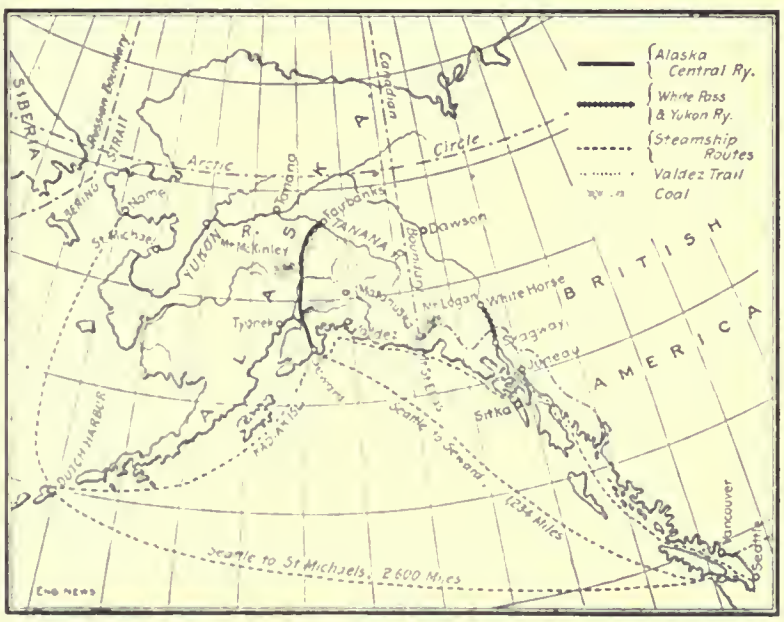
The Copper River District, Alaska.

Written for the MINING AND SCIENTIFIC PRESS
By W. M. BREWER.

I.—THE RAILROAD FIGHT.

At the present time the most direct route by which to reach this portion of the interior of Alaska is by way of Valdez, at the head of Prince William sound; thence 80 miles northerly along the Valdez and Fairbanks trail to Tonsina telegraph station where the Tonsina river (a tributary of the Copper) is crossed; and a short distance north from the bridge the traveler leaves the Government trail and branches off toward the east, following down the Tonsina river to near its mouth, a distance by trail about 25 miles; at this point the Copper river is crossed by means of a boat-ferry and swimming the horses, thence the trail continues in a general easterly course and crosses the following streams: Horse creek, Strelna, Kotsina, Kushkilina, and Lakina rivers. All of these, with the exception of Horse creek, empty into the Chitina river, which is itself a tributary of the main Copper river. The total distance from the Copper river to the crossing of the Lakina river is approximately 55 miles by the present trail, but this could be very much shortened.

As a matter of fact, while this mining district has been always designated as the Copper River district it would be much more appropriate to refer to it as the Chitina River district. Chitina really means 'copper river' in the Indian language; 'chit' standing for copper, and 'ina' for water or river. The Indians for generations have been finding specimens of native copper in and near the Chitina and its tributaries, while the stream known today as the Copper river lies to the westward of any known discoveries of copper ore.



Map of Alaska.

The discovery of copper in the mountains surrounding the headwaters of the Kotsina, Kushkilina, Lakina, and Chitina rivers was first made in 1899 by a party of prospectors known as the Hubbard-Elliott crowd. The discoveries made by members of this party are situated on a stream known as Elliott creek, a tributary of the Kotsina river, where a large number of claims were staked which today comprise a portion of the holdings of the Hubbard-Elliott Mining Co. This property is near the western boundary of the mineralized belt of this part of Alaska, and exploration has been carried on by prospectors to the east and northeast of these claims, although some property has been located adjacent to the Kotsina river itself.

During the past summer I made a hurried trip through a portion of this mining district, confining my examinations to the mountains adjacent to the headwaters of the Lakina. As far as the remainder of the district is concerned I visited none of the camps, but was enabled to form some opinion as to the problems confronting the operators of most of the properties lying between the Kotsina river and the Lakina, because the route followed by the trail has been laid out with a view to bringing the main trail in as close touch as possible with the various camps.

There is no question but that the most important problem to be solved in this part of Alaska is the question of transportation, and I deem that a brief discussion of the projected lines of railroad, and the difficulties attending construction, will not be out of place. For several years past the newspapers have made reference from time to time to railway building in this portion of Alaska, but it is impossible to judge of these matters except by making a personal investigation.

It was not long after the town of Valdez had been located at the head of Prince William sound (and Fort Liscum had been built about three miles distant from the town and on the opposite side of the bay) that John Rosene, then president of the Northwestern Steamship Co., conceived the idea of building a railroad from the vicinity of the town of Valdez into the interior by way of the Lowe river, Keystone canyon, and over the summit of the Coast range by one of the passes. He organized the Copper River & North Western Railroad Co. and made a futile attempt to move the town of Valdez to a site selected by himself about three miles down the bay, thereby expecting to seek relief from the ever present danger to life and property which has always menaced the town because of its situation in such close proximity to the foot of the Valdez glacier. Although he built a wharf and did considerable work on this proposed townsite, he was entirely unable to persuade any of the townspeople to move to his new site, and as a matter of fact no vessels ever landed there.

At about the same time Colonel Swanick, who had during the previous year been engaged in constructing a portion of the Alaska Central railroad from Seward at the head of Resurrection bay, came to Valdez and proposed to build from the old town into the interior by a route paralleling that selected by John Rosene for the Copper River & North Western Railroad.

This brings the history of railroad construction up to the season of 1905, during which year both of these companies did more or less work of a preliminary character, such as locating lines through Keystone canyon, with some grading, enough to cause a great deal of newspaper discussion; and in the fall of that year Mr. Rosene was successful in securing recognition from J. Pierpont Morgan, who proposed to continue the construction of the Copper River & North Western Railroad, in consideration of a contract with the owners of the Bonanza mine, which is near the head of the Chitina river. It was understood generally that at that time the Guggenheims had become heavily interested in the Bonanza property, and that the contract made by Mr. Morgan was between himself and the Guggenheims by which the railroad should have the contract to haul all the ore from that property for a term of years.

Previous to this, the town of Catalla, near the mouth of the Copper river, and some distance easterly from Cape Hinchinbrook, had been selected by Pittsburg capitalists, whose assistance had been secured by Dr. Bruner, as a desirable ocean terminus for a railroad into the interior of Alaska. This project, however, received but little consideration from men who knew the Coast, because Catalla is situated at a point where there are no harbor facilities and where the ocean swell breaks directly on the shore, and during several months in the year vessels can only discharge freight and passengers with great hazard and very considerable delay.

Early in 1906, M. J. Heney and associates actually commenced the work of railroad building, having selected the old Eyak cannery site on Cordova bay for their ocean terminus. At this point the harbor facilities are exceptionally good and afford safe shelter for vessels of any draught at all times of the year. Mr. Heney pursued a policy entirely at variance from that pursued by his competitors. He commenced railroad construction in earnest, instead of in the newspapers, which had been the rule previously followed by all his competitors, and by November, 1906, he had graded several miles of roadbed and had laid rails from the wharf at Eyak for a distance of some four or five miles.

Early in the summer of 1906, J. Pierpont Morgan's representative, M. K. Rodgers, arrived at Valdez to report on the situation instead of bringing in a big gang of laborers prepared to commence construction work on the John Rosene right-of-way. This gentleman, on investigation, not being satisfied with the condition of the surveys, sent parties of engineers into the field to run preliminary lines. He ascertained that a portion of the road would be on a 3½% grade if constructed from Valdez. Thereupon he set out to find a route with an easier grade, and in company with Captain Jarvis made a boat trip down the Copper river. They found that it was quite feasible to build a road on a water grade up the river and selected Catalla as their ocean terminus, securing at the same time enough land for terminal purposes.

The situation at this time was as follows: The Valdez route selected by John Rosene was turned down by Mr. Rodgers, representing J. Pierpont Morgan. On the Valdez route as selected by Colonel Swanick, some construction work was being performed, and about three miles of grading had been finished, besides a wharf and approach on which rails had been laid, the first spike having been driven by Judge Gunnison while he was in Valdez holding a term of the United States District Court. M. J. Heney was pushing construction on his line from Eyak or Cordova, as the place had been re-named. The Dr. Bruner outfit was doing some little work at Catalla on its terminal ground. M. K. Rodgers had made a report to his principals advising construction from Catalla because, while it was quite true that considerable expense would be involved in constructing such substantial breakwaters as would insure good harbor facilities, yet the road when constructed would be on the east side of Copper river, thus avoiding some very expensive bridge work which would be necessary in the case of the Heney route, as the railroad on that line would approach the Copper river from the west side.

The engineers who located the line for Mr. Heney report an average grade of ½% from Cordova to the district in which the copper mines east of the Copper river are situated, and that while the bridge work necessary to cross the Copper river would be expensive, yet it is quite within their power to erect such a bridge as will be perfectly safe and secure.

During the winter of 1906 and 1907, J. Pierpont Morgan and his associates bought out the Heney project in its entirety, thus removing the most dangerous of all the competitors from the field. Mr. Rodgers, who was managing for Mr. Morgan on the Pacific Coast, did not contradict any newspaper reports to the effect that not only would the Heney route from Cordova be abandoned but that the rails already laid would be taken up and all the movable equipment taken to Catalla. On the opening of the season of 1907 active work was commenced by Mr. Rodgers and the Dr. Bruner party at Catalla, while all the other projected routes were, so far as could be judged from the conditions, abandoned. One advantage in building from Catalla, provided there were good harbor facilities, was that the distance from that point to the coalfields is only about 20 miles, while from Cordova to the coalfields over the route selected by Mr. Heney is about 70 miles.

Soon after the two opposing forces had commenced work at Catalla, in the late spring of 1907, friction occurred because of the attempt of the Morgan workmen to cross the right-of-way of the Bruner railroad. In this the Morgan party was successful after a skirmish in which the opposing forces used clubs, axes, and pick-handles for weapons. This followed an ineffectual attempt on the part of Dr. Bruner's men to obtain an injunction from the court at Juneau restraining the Morgan outfit from securing the crossing.

During the summer and autumn of this year the loss from wrecked lighters and because of the delay occasioned through holding vessels in the roadstead to await favorable opportunities to discharge their cargoes has been enormous, so great indeed that recently Mr. Morgan and his associates made a contract with Mr. Heney to return to Cordova and construct the railroad according to his original location. It is reported, however, that this company intends to continue building the line from Catalla to the coalfields and from there to the point where it will form a junction with the Heney road building up Copper river. In the meantime it is reported that the Dr. Bruner party is also continuing building operations toward the coalfields.

During the month of August Mr. Reynolds, the president of the Alaska Development Co., created quite a boom in Valdez by proposing to take over the Colonel Swanick project and build that road to the summit beyond Keystone canyon, making the promise that he would have it in operation in time to haul freight out from Valdez during the coming winter. When his surveyors started to run lines through Keystone canyon the Copper River & North Western Railroad Co., or Mr. Morgan's party, immediately discovered that the old John Rosene route from Valdez had not been abandoned and an attempt was made to stop Reynold's surveyors from continuing their work. This attempt was so forcible that several men were wounded by shots fired at Reynolds' men, who are reported to have been unarmed. Later, the Reynolds project fell through because of his inability to finance it, and several hundred laborers were landed in Valdez unable to secure their pay, thereby causing considerable consternation among the people of that town, who for a time apprehended that rioting might result.

Judging from the past actions of the Morgan party, an outsider can only conclude that they have determined to control southwestern Alaska.

ALLUVIAL DEPOSITS in Japan are represented by alluvial gold in the district of Esashi, in Hokkaido, and iron sand in Chugoku. The former is derived from auriferous quartz veins in the Paleozoic rocks and deposited in the river-beds.

Leasing the Federal Coal Lands.

Written for the MINING AND SCIENTIFIC PRESS
By H. FOSTER BAIN.

Whether the remaining coal lands belonging to the United States shall be sold or held for development under a leasing system is a question likely to come sharply to the front at Washington this winter. The President has recommended a leasing system. He has in view seemingly the better safeguarding of our future by conserving our mineral resources and feels that the public as a whole is more trustworthy than are individual owners. It may not be unprofitable to consider briefly what may be urged for and against the proposed leasing system.

In the first place it is to be remembered that the American system of allowing mineral lands to pass into the hands of individuals without recourse is unusual. In many countries the leasing system now obtains and in the United States it was in operation in the Upper Mississippi valley lead district for many years. In certain cases, in lieu of lease rentals, special taxes are assessed against mines and mining. In the United States such special taxes are not common and in general mining property is considered as only taxable on the basis of any other property; though the method of assessing and collecting the tax may be special, as it is in the case of railways and indeed, other kinds of property.

The change from the early system of leases to the present one of individual ownership was brought about mainly by the desire to promote the rapid development of the country and to afford the largest possible scope for development of individual initiative. The Government has never been run as a money-making business and the ownership of land, mineral or otherwise, has never been looked upon from that point of view. Land of all kinds has been sold or given away with practically no thought of its present or future value, but with the expectation that this would not only give our citizens the best chance for their own development but would also develop taxable wealth far greater than the value of the land itself. There can be no question that in the past this policy has justified itself and our gain in material wealth and in the quality of our citizenship, measured only as wealth-producers, has been worth many times any reasonable value that might have been placed on the land. There may nevertheless be reasons why a policy good in the past should now give place to one better for the future.

Considering the matter first as a business proposition, there can be no question that if we as individuals owned the coal lands and did not need the money represented by that ownership, we would not sell them at the present price or at any reasonable multiple of it. The revenue derived from the sale of mineral lands is so small as to be negligible and the Government, because of its greater credit, could if need be, borrow money to carry the lands at a lower rate of interest than could any individuals or corporation. As a business proposition then we need not hesitate to do collectively what we would do individually. The land will never sell for less money than now. Furthermore when the coal is mined in the years to come, the interest charge against the investment will be smaller if the Government carries the land than if it be disposed of to private parties. Under these conditions, the possible selling price will be lower. It goes without saying that a low selling price for fuel is a matter not only of individual interest but of prime importance to our very civilization.

In the second place, the separation of mineral title from surface title and the disposal of the latter would open the way to the settlement of certain lands available for dry farming which though underlain by coal are not of such immediate value to the farmer as to warrant his paying a coal price for his land. It is certainly reasonable that each piece of land should be made available as rapidly as possible and if the presence of coal is going to keep land out of cultivation which might be farmed, a change is desirable.

It will probably be conceded by everyone familiar with the conditions that the present mineral land laws, and particularly the coal land laws, need thorough revision whether we go to the lease basis or follow the present plan of selling the land. It has been abundantly shown that the present laws do not permit of the honest acquirement of tracts of coal land in sufficient area to meet modern conditions of development. Indeed they were not designed to do so. They were planned on the basis of individual development of small mines and were a part of the general policy of helping the individual to land-ownership. The very fact that they do not now do this is in itself a strong argument against the continuance of the system. If the sale of coal lands does not meet this prime condition of helping the establishment of individual citizens on an independent basis, it fails in its most important mission. One needs only to read the testimony in the various land fraud cases recently tried, to realize that the laws as now existing are of benefit principally to unscrupulous speculators and open the way to debauching citizens at the same time that they unfairly penalize corporations and individuals honestly trying to develop the coal-mining industry.

Modern conditions demand that large tracts of coal land should be given for development and mining into the hands of single companies. Are we prepared to give this land irrevocably to them by sale, or is it better to lease for a term of years under such terms and conditions as may be fair to all interests? A few years ago it was the custom to give perpetual franchises for street railways, public water systems, and other public utilities. It is now generally recognized that this is both unwise and unnecessary. Capital is found for all these enterprises upon the basis of franchises extending from 20 to 50 years, and as the various franchises expire new ones are drawn upon terms that better meet the conditions. No one can foretell for 50 years what will be wisest as regards conditions of coal mining. Why then bind ourselves for eternity? Is not coal a prime necessity, just as water and local transportation are? There is no injustice in this plan since a mining plant works itself out within the limits of such a term of years, and a new plant is necessary in any event. All coal mining is done on the basis of amortization of plant and land investment, and if a royalty be paid in place of interest and sinking fund charges, the financial transaction is the same. This royalty need not be burdensome. The President has stated that from his point of view the matter of revenue is not important. The royalty may be made as low as is necessary to get the best results. This is probably the right attitude, though it may be pointed out that leasing is nothing new in the coal industry, and everywhere there are mines working on royalties side by side with others which have all interest charge on land investment much lower than the royalty. While coal is now mined and sold on a relatively narrow margin, any ordinary royalty is a very small element in the cost of the coal, and a royalty which would make the administration of the coal lands entirely self-sustaining would be no burden to mines working on government land.

What then would be the advantage of the leasing system? The principal advantage would be that it would leave the way open at the termination of any existing lease

for a readjustment of conditions. When the land is sold the Government has no further control of it and must rely upon indirect uses of its power of taxation for any regulation which changed conditions may make necessary. Taxation should be on its own basis and not distorted to serve other uses. Aside from the power of taxation, Federal and State, there remains the police power of the State. This extends only to matters of safety and affords no means of controlling the conditions of mining as relates to waste. The latter may be written into the terms of a lease with the single reservation that the terms may not be made so onerous as to leave no profit. In that event no one will be found to take up the lease.

It goes without saying that leases will need to be carefully drawn, but being in the nature of bargains the combined experience of the coal operator and the government expert would be brought to bear on them. In the leases, so long as leased mines were in competition with mines on private lands, many concessions would need to be made to the operator. All this could, however, be done without in any way altering the fact that a re-adjustment would always be possible at the termination of one lease and the granting of another and that this is not possible when the land is once sold.

The practical difficulties in introducing a leasing system in the coal business are probably less than in the case of any mining industry, save possibly oil. Coal-mine operators are already thoroughly familiar with the leasing system. It is true that the movement has recently been away from leasing and toward ownership but there are special reasons for this.

It goes without saying that if the coal lands in the various Western States are to remain Government property and hence for all time exempt from State and local taxation, some compensation, such as a division of royalty, should be introduced. It also seems clear that if this system is introduced it will care for high administrative talent and officers thoroughly familiar with coal mining. This is an added reason for the establishment of a Mining Service or Bureau of Mines as has been recommended by the President and is now under consideration at Washington.

Summarizing the reasons for the introduction of a Federal coal-land leasing system, they are:

(1) The failure of the present coal-land laws, designed to meet the conditions of small ownership, to measure up to modern needs and the resulting necessity of a thorough revision.

(2) The necessity, if the sale plan be continued, of selling large tracts of valuable coal-lands to individual corporations. It is at least doubtful whether public opinion will now permit of this.

(3) The higher ultimate cost of the coal if the reserves are to be carried at private rather than at public charge.

(4) The possibility under a leasing system of revision of terms from time to time to meet new industrial conditions.

(5) The possibility from time to time of providing for less wasteful development and better conditions as regards safety of men and property.

(6) The reserving to future generations of some control over one of the prime necessities of our civilization.

DURING the last 50 years of mining in Great Britain the yearly number of fatal accidents has not varied very much, keeping around an average of 1100 accidents per year. In this time the number of miners employed has increased steadily from 200,000 in 1851 to over a million in 1906 so that the percentage of fatal accidents has greatly diminished.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

I. C. L., of Nevada City, sends Basalt.

J. F. P., of Fairview, Nev., sends a specimen of Rhyolite.

M. L. M., of San Juan, Porto Rico, sends altered Andesite.

Quartz containing Graphite was received from W. H. W., of Amalie.

J. C. S., of Jerome, Ariz., sends a specimen of Chlorite-Mica Schist.

Specimens from Nogales, Sonora, are: No. 1, Trachyte; No. 2, Rhyolite.

The samples from Rawhide appear to be altered volcanic Breccia.

The rock from Clinton, S. C., marked X. Y. Z., contains Arsenopyrite.

Gypsum and Carbonaceous clay were sent by B. G. R., of Taos, New Mexico.

The specimen sent by J. P., of Eureka, Nev., is plumose Pyrolusite in quartz.

The specimens from Soulsbyville marked J. L., are: No. 1, Schist; No. 2, volcanic Tuff.

A specimen of mineralized Diorite was received from T. McD., of French Gulch, California.

The rocks from R. N. B., of Boise, Idaho, are: No. 1, Basalt; No. 2, Andesite; No. 3 and 4, Trachyte or Andesite.

J. C. H., of New York, sends specimen containing a quartzitic vein carrying Pyrite and stained red by the oxide of iron.

The specimens from Ventrigger, Cal., marked M. J. S., are: No. 1 and 3, decomposed granitic rock; No. 2, brown Calcite.

The brilliant yellowish-red mineral from Tucson, Ariz., is Vanadinite, the vanadate of lead. Associated with it is Descloizite, another lead vanadate.

The specimens from Nelson, Nev., marked F. E. A., are: No. 1, Biotite-Andesite; No. 2, Andesite; No. 3, Granite; No. 4, Quartzite; No. 5, Quartzite; No. 6, Chert.

W. L. B., of Greenville, Cal., sends: No. 1, Rhyolite; No. 2, Quartz-Porphyry; No. 3, Porphyrite; No. 4, Diabase; No. 5, Porphyrite; No. 6, Bornite and Chalcopyrite; No. 7, Chromite; No. 8 and 9, Serpentine.

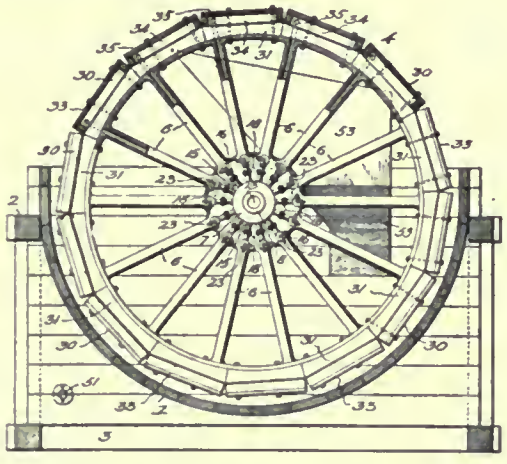
M. J. S., of Palomas, Ariz., sends: No. 1, Cuprite, Malachite, and Quartz; No. 2, black Limestone and Quartz; No. 3, Hornblende; No. 4, specular Hematite; No. 5, specular and red Hematite; No. 6, specular Hematite in rock.

The specimens from Wonder, Nev., marked H. G. G., are: No. 20, Rhyolite; No. 21, Nevadite; No. 22, Diabase; No. 23, Breccia; No. 24, altered Rhyolite; No. 25, Rhyolite-Breccia; No. 26, altered Rhyolite; No. 27, altered Rhyolite; No. 28, Diabase.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

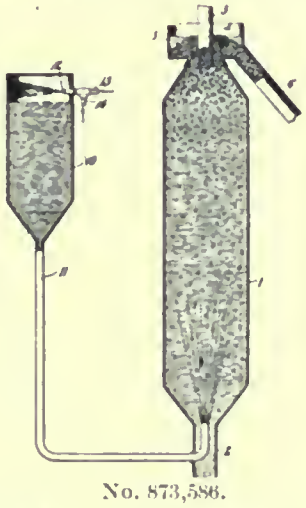
REVOLVING FILTER.—No. 872,616; Oscar H. Fairchild, Denver, Colo., assignor of two-thirds to William Archer Diboll, Denver, Colorado.



A revoluble filter, comprising a semi-circular solution tank; a wheel mounted in said tank so as to be partially submerged, and having passages which connect on one side with a vacuum tank and on the other side with a source of fluid under pressure; filter boxes on said wheel communicating with said passages, and automatically operated valves for controlling said passages.

HYDRAULIC SIZING-MACHINE.—No. 872,620; Louis C. Graupner, San Francisco, California.

No. 872,620.



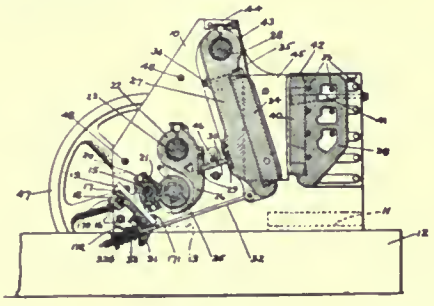
No. 873,586.

In a sizing and separating apparatus, the combination of a settling receptacle, said receptacle having a wall adapted to connect with the interior of a grinder, an overflow valve connected with the upper part of the receptacle through which pulp held in suspension in the upper part of said receptacle may be classified and delivered, said wall comprising adjustable gates arranged in overlapping order and having channels connecting with the interior of the receptacle, and an oversize valve in the lower part of the receptacle, said receptacle having a return port for returning the coarser material to the grinder.

APPARATUS FOR SEPARATING THE METALLIC PARTICLES OF ORES FROM THE ROCKY CONSTITUENTS THEREOF.—No. 873,586; Dudley H. Norris, New York, New York.

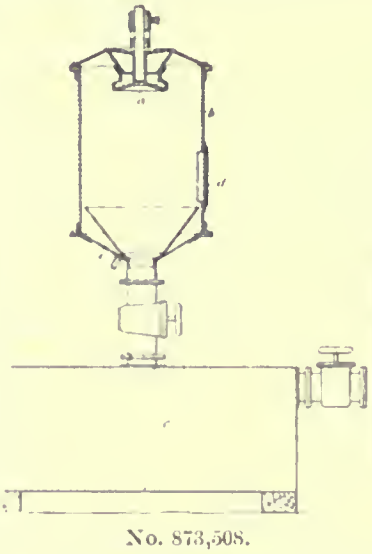
An apparatus of the character described, comprising a receptacle having its upper end open to the atmosphere and adapted to receive a flowing mixture of pulverized ore and water, means for introducing a stream of water containing air in solution into the mixture in said receptacle to cause infinitesimally small nascent bubbles of air to form in said mixture and rise to the surface thereof to collect the metallic particles of the ore together, a member arranged at the upper end of said receptacle to receive the metallic particles of the ore, and a discharge pipe at the lower end of the receptacle out of which the water and the rocky particles of the ore pass; substantially as described.

MULTIPLE ROCK-CRUSHER. No. 873,080; Edwin S. Philips, Kennett Square, Pa., assignor to The American Road Machine Company, Kennett Square, Pa., a Corporation of Pennsylvania.

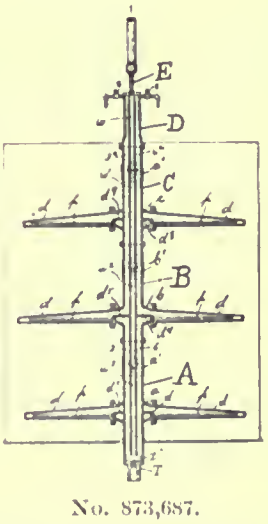


In a rock crusher, the combination with the side plates, of a shaft between the side plates and a plurality of moving jaws swinging thereon, a second shaft between the side plates back of and below the first shaft, and a plurality of tumbler-levers, corresponding in number to the moving jaws, swinging thereon and actuating the moving jaws respectively, a main cam shaft between the side plates back of and below the second shaft, cams fixed thereon corresponding in number to the moving jaws and actuating the tumbler-levers respectively, a cross-brace between the side plates back of the main shaft, and brackets on the cross-brace having bearings for the main shaft extending between adjacent cams, substantially as described.

ELECTRODEPOSITION OF COPPER AND OTHER METALS.—No. 873,508; Sherard O. Cowper-Coles, London, England.



No. 873,508.



No. 873,687.

In the electrodeposition of metals from solutions which have to be maintained in an oxidized state, the process of freeing the solution from impurities in suspension, which consists in passing the same through an atomizer and bringing it into intimate contact with air so as to convert and maintain it in an oxidized state, substantially as described.

ROASTING-FURNACE SHAFT.—No. 873,687; Grant B. Shipley, Milwaukee, Wis., assignor to Allis-Chalmers Company, Milwaukee, Wis., a Corporation of New Jersey.

A stirring shaft provided with a plurality of hollow arms, said shaft being also provided with passageways communicating with the interiors of said hollow arms for supplying a cooling medium thereto and with passageways communicating with the interiors of said arms for the discharge of the cooling medium therefrom, a separate discharge passageway being provided for each arm, said passageways of said shaft being adapted to convey the cooling medium in contact with said shaft to cool the same.

The Outlook for Copper.

Written for the MINING AND SCIENTIFIC PRESS
By MISHA E. APPELBAUM.*

The year 1907 proved as sensational in the copper industry as it did in the general world of finance. Against the most flourishing conditions existing at the beginning of the year a demoralized state of affairs prevailed in October and November, and it was not until a week or so before the present writing that the copper market showed a resumption of activity and hopes were felt for a substantial, though gradual, improvement.

At the end of 1906 it was the general opinion that the stocks of copper were very small and that a good business would result during at least the first half of 1907. Copper continued to advance from the closing price of 24 cents until a level of about 26 for lake and electrolytic brands had been established. The subsequent history of the market for 1907 is a simple one. During the first half of the year a good business was done in copper; then the American consumers withdrew from the market, and a general business depression having already made itself felt, they were not tempted by even the heavy reductions in official prices and thus the market declined to 25¼, to 22, then to 18, 15, and 13½, and finally sold in October as low as 12 cents. Just at the height of the financial panic a little spurt occurred in copper and this carried the price up to 15 cents, but with the approaching holidays, during which most of the American consumers closed their mills for a week or 10 days for the purpose of taking inventory, and their refusal to make commitments before money became easier and a revival of confidence took place, copper again sagged down to 13 cents. Though the official quotation was 12¾ to 13 cents it was practically impossible to obtain copper at that price, and some of the American consumers having large orders under 13 cents and being unable to obtain the metal became rather nervous and increased their limits, with the result that on December 21 the only copper obtainable was for December and January delivery at 13⅜ and 13⅝ for February. Beyond that it was practically impossible to obtain copper at around these prices.

A good many criticisms have been directed against one of the leading selling companies for the manner in which prices were held and broken, but it should be remembered that no one foresaw the panic and therefore it is my opinion that the decline in copper has also been one that no one could foresee. There is also a good deal of talk as to the amount of copper stocks in Europe and on this side. I do not think that in view of what has happened in copper it is possible for anyone to estimate even within 25,000,000 to 50,000,000 lb. of the actual stocks on hand. The only public figures deserving of credit are those quoted by the *Boston News Bureau* of December 13, in an interview with John Gillie, general superintendent of the Amalgamated properties. He reports an accumulation in October of 300,000,000 and sales of 161,000,000 lb., so that one naturally concludes that there are 139,000,000 lb. of copper still unsold; and one must also consider his remark that some of the sales have been made into February, so that perhaps the actual stock on hand is between 150,000,000 and 160,000,000 pounds.

With so many mines already shut down and only a fair business doing in copper, it is my belief that the surplus will shortly be wiped out and that unless the mines are opened a sharp squeeze will result. And since at the present moment most of the large mines can produce copper with profit and pay good dividends on a 14 to 15 cent market, it is to be hoped that when the price gets to that level the mines will open and a conservative and steady level be established, enabling both the consumer and the producer to do business at mutually advantageous prices. At a 14 to 15 cent level the production would continue at a satisfactory rate and the consumption would certainly not be restricted. Of course, a good deal depends on the financial and business condition of the country and if we have seen the worst and the expected improvement comes, we shall see a good business in copper.

*President of the New York Metal Selling Co.

Commercial Paragraphs.

THE FULTON IRON WORKS wish to inform their friends and the trade in general that F. H. Johnson is *not* connected with their company.

THE BOX ELECTRIC DRILL CO., of 115 Broadway, New York, issues Bulletin No. 201, describing the special drill manufactured by them.

THE WESTINGHOUSE MACHINE CO., of Pittsburg, have manufactured storage batteries for a number of years, but they have just issued the initial catalogue on the subject, entitled 'Westinghouse Storage Battery for Portable Use.'

THE KROGH MANUFACTURING CO. announces the completion of a three-stage 300-ft. head Krogh centrifugal pump direct-connected to a general electric 220-volt A. C. motor for the Channel Mining Co., at San Andreas, Cal. This pump will replace one four-stage and one three-stage pump of other designs now being used to unwater the mine.

L. S. PIERCE, of 1650 Champa St., Denver, recently shipped one 50-ton Pierce Amalgamator to the Atlas M. & M. Co. at Ouray, Colo.; one 12 by 24-in. machine to Johannesburg, South Africa, through the Export Shipping Co., of New York; and two 40-ton machines to Baily & Clark, at Portland, Oregon. Catalogue No. 10, which describes the machine fully, is ready for distribution and will be mailed upon request.

THE MEXICAN MINES-PROSPECTS DEVELOPMENT CO. has been organized in Mexico City for exploration, prospecting, development, and the operation of mining properties in various districts of the Republic. The board of directors comprises W. Landa y Escandon, J. L. Requena of the Dos Estrellas mine; A. G. Mills, of the Otis Elevator Co., M. G. Harner, and P. A. Babb, the last named being the company's manager and consulting engineer. The company already has several properties, which are to be developed.

THE ALLIS-CHALMERS CO. describe the Tremain steam-stamp in their bulletin No. 1408. This stamp has been designed especially to meet the demands of those who own mining properties in the first stages of development; enabling them to establish a thoroughly good crushing, amalgamating, or concentrating plant of moderate capacity in the shortest possible time, with the least material, and for the least money. This machine has not only proven itself highly successful for this purpose, but has shown an economy in all matters pertaining to its operation which is remarkable, and which compares very favorably with results obtained in works of larger capacity; the original plant can be readily and advantageously augmented from time to time as the development of the mine progresses, by the addition of more machinery, at a cost a little more than that of the machines themselves. The Tremain steam-stamp requires no engine, shafting, pulleys, belting, gears, cams, or tappets. Not being dependent on cams for raising or gravity in dropping, the speed and capacity per stamp-mill is, therefore, more than doubled. Owing to the compact construction, it can easily be carried on mule-back over mountainous roads.

Catalogues Received.

THE CLING-SURFACE CO., of Buffalo, N. Y., has issued a catalogue entitled 'The Treatment of Belts and Ropes for Service and Profit.' In addition to describing the company's manufacture, 'Cling-Surface,' the catalogue gives much useful information about the proper treatment for belts and ropes under the various vicissitudes to which they are subjected.

THE B. F. STURTEVANT CO., of Hyde Park, Mass., have issued 'Bulletin No. 151, Steam Turbines.' This describes and illustrates the steam turbines manufactured by it; these are of the impulse type, in the sizes below 200 hp., single stage, in the larger sizes two to four stage. The bucket-wheel is a single forging of best open-hearth steel. One of these turbines is in use at Bridgeport, Conn., where it is giving satisfactory service.

Editorial.

THE TRANSVAAL mines ended the year with a record output of 583,525 ounces of gold for the month of December, making the total yield for the year no less than 6,451,383 ounces, worth $133,350,086, which is a gain of $14,137,149 as compared to 1906.

CALIFORNIA is rich in minerals and has been the place of origin of many new mineral species. No one is better fitted to write on the subject than Mr. Arthur S. Eakle, professor of mineralogy in the State University, and many of our readers will find it interesting to note the array of minerals that were first found within the boundaries of a region so rich in natural resources.

IT APPEARS that a dispute as to the ownership of ore near the boundary separating the La Rose and Right of Way mines at Cobalt was settled by a commission of engineers, consisting of Messrs. R. Askwith, R. W. Brock, A. A. Cole, J. B. Tyrrell, and A. Wilson. They examined and sampled the workings, and their decision has been accepted by the parties concerned. This is a precedent worthy of imitation.

ACCORDING TO the statistics of the New York Stock Exchange, the combined sales of 12 active issues totaled 142,698,873 shares, or 73% of all the business transacted. In the case of 11 issues the number of shares traded exceeds the total stock, and in the case of Reading, American Smelting, and Union Pacific, the whole of the outstanding common shares of these companies changed hands from 17 to 20 times during the past year. This is pretty good proof that gambling, not investment, dominates the activities of Wall Street.

THE *Evening Scream* states that a professor of history in Stanford University has been examining gold mines at Bullfrog, Nevada. We hope he will not be the victim of either his own enthusiasm or that of others. Professors of history are as appropriate in a gold mine as a bull in a china-shop and as provocative of a smash if taken seriously. Or was it history in the making that the professor was studying on the banks of the Amargosa? He had better avoid such incubators of events, until, like the brine of the desert, they have been distilled by Time.

AMONG the small banks that were overwhelmed by the recent panic was the Swickhimer bank of Rico, in southwestern Colorado. This institution is controlled by David Swickhimer, the man who discovered the Enterprise mine in 1887 and caused the development of Newman hill, at Rico. The same indomitable courage that caused him to stick to his prospecting, in the face of many difficulties, and finally to uncover the ore measures

that made Rico a rich mining district, was made manifest when the financial flurry compelled his bank to suspend payments for a time. It is pleasant to learn that the depositors have such confidence in Mr. Swickhimer that they have arranged to give him a year wherein to arrange matters, and the meeting at which this was decided was marked by an unusal manifestation of goodwill toward the old miner and enthusiastic expressions of faith in his absolute integrity. Even a bank failure may enrich humanity.

NEVADA'S latest discoveries of gold are at Rawhide, a mining camp which is 28 miles east of Schurz, at the head of Walker lake. Like most of the desert goldfields, this new one is lacking in wood and water. Piñon pine sells for $1 per sack and water at $2 per barrel. Coal is worth $45 per ton. This recalls the early days of Tonopah, and, as at Tonopah, the energy of the exploiters of mineral wealth will conquer the natural obstacles, transforming the desolation of the desert into a hive of industry. We wish good luck to Rawhide. At present, the new district is controlled by a few vigorous men and the stock market feature of mining is pleasantly absent. The leasing system is in vogue and good ore is being broken from quartz stringers in andesite.

WE WELCOME the letter by Mr. John A. Reid on 'College Instructors.' Professors are so accustomed to lecturing students that a little of their own medicine may do them good. The best of them will welcome an expression of ideas in regard to teaching when offered by the earnest-minded members of their own classes and among the professors there are not a few possessing the supreme test of the sense of humor, namely, the capacity to see a joke against oneself. Mr. Reid's criticisms and suggestions are made in good faith—for that we vouch—and we are glad of his endorsement of the proposal made by the present writer in another place, to the effect that the chairs of metallurgy and mining in schools of mines ought to be so endowed as to permit of one professor lecturing while the other is in the field, not practising but gathering information at first hand, so that the professor of mining becomes a dual personality and is thus enabled to perform what is now impossible, namely, lecture on theory while in close touch with the practical working of his subject. If Smith and Jones were both appointed to the professorship of metallurgy in the College of Minerva, Smith would devote himself to a term of lecturing while Jones would be at Bingham, Anaconda, or Tennessee studying copper smelting, or at El Oro and Kalgoorlie investigating cyanide practice, or at Wallace and Broken Hill studying the treatment of lead ores. At the end of a semester Jones would arrive at the College bubbling over with ideas and information for the use of his students, while Smith would be released from lecturing and it would be his turn to make a *voyage metallurgique*. The plan is feasible; it would cost about $15,000 per annum, that is, $5000 as salary for each professor and $5000 for traveling expenses. That is all. And it would be better than the erection of a marble palace to commemorate a late lamented or the donation of a library to celebrate the success of a champion rebater.

JAMES J. HILL is quoted as saying that one beneficial result from the curtailment of industry is that "one can get a day's work out of the laboring man these days." Others will echo this statement. The cost of mining has risen seriously by reason of the excessive demands of the labor unions, operators being unwilling to have a strike and interrupt work when the metal markets were at the top notch. Mr. James Douglas is credited with the statement that the cost of producing copper has been advanced three cents per pound during recent years, and in southern Arizona the shortage of fuel, car congestion, and labor troubles have been the main factors in causing this increase. Elsewhere an increase of two cents per pound is a fair estimate, such an addition being due mainly to the higher pay and less efficiency of the wage-earner, together with the increment of cost for all supplies and machinery. Undoubtedly, the labor market has been as demoralized as that of the metals, and efforts to monopolize the one and the other have been equally detrimental to legitimate industry. The mine manager has been between the devil of a tyrannical labor union and the deep sea of unrestrained speculation among metal brokers. He prays to be delivered from both, and it is unfortunate that such relief cannot come save through the drastic discipline of hard times.

AN ALASKAN MINER, under the pseudonym of 'Musher,' writes to suggest that the Survey do a little real prospecting on its own account, by grubstaking a few of the younger members of that scientific bureau. The charge that the Survey reports are so late in their appearance as to serve mainly as obituaries on mining districts is one that might have been made a few years ago, but it is rarely true today; at the risk of seeming inconsistent we venture to say that the reports are now so prompt in their appearance as to be in danger of being compared to 'write-ups,' journalistic performances of an ephemeral kind. As far as our friends the 'mushers' of the North are concerned, surely they have abundant cause to feel grateful to the United States Geological Survey, for the bibliography of Alaskan reports is already voluminous; in fact, on the very day the letter of our correspondent arrived we were making mental note of the splendid mass of information on Alaska given out by the bureau at Washington; why, there is nothing like it, no mining region in the world has been so intelligently and usefully served in the matter of scientific investigation. Alfred H. Brooks and his corps of assistants have not only issued a number of geological monographs of unquestionably great value but they have done some of the very pioneer work mentioned by our correspondent, not, it is true, finding ore deposits, though even that has been done incidentally, but in making surveys and maps of comparatively inaccessible tracts, exploring rivers, climbing mountains, correlating geologic facts, and

co-ordinating all the information extant at the time. No; Mr. Musher, you have barked up the wrong tree.

Federal Bureau of Mines.

BY THE COURTESY of Mr. W. P. Englebright, one of the representatives for California in the Congress of the United States, we are in receipt of a copy of the bill introduced last week for the establishment of a Bureau of Mines in the Department of the Interior. This is the result of several years of work on the part of the American Mining Congress, which at its successive sessions has ventilated the subject, passed resolutions asking for Federal recognition of the mining industry, and urged the creation of a Department of Mines, with a cabinet minister at the head of it. Whatever sins of omission and commission may be charged to the Mining Congress, it is only fair to acknowledge that the near probability of the creation of a mining bureau at Washington is to be credited to Mr. James H. Richards and his friends, who have labored unremittingly for this achievement. And yet the outcome is not exactly what they desired. We are to have a bureau and not a department, it being known that President Roosevelt does not want any more cabinet officers and considers that the Cabinet is already too much like a town meeting. Moreover, every department includes a number of independent bureaus; for example, in the Department of Agriculture there are twelve of them. At present there are but few bureaus at Washington that are so closely related as to be properly included within a Department of Mines. Of such the most important is the Geological Survey, which has close relations with the Land Office, the Forest Service, and a number of other branches of government work, so that at present it would not be likely to be placed within a Department of Mines. The preparation of the general topographic map of the United States, for example, is not related directly to mining; in fact, much of the pressure for this map comes from the general staff of the Army, from educational institutions, from drainage interests, and others not connected with mining. But the strongest argument, to our mind, for the creation of a bureau as against a department, lies in the fact that the chief of the latter is a cabinet officer, who changes with each administration (if not, as according to recent experience, at least twice as often), while a bureau would be headed by one whose appointment would be subject to civil service regulations and, like the Director of the Survey, would be marked by a long tenure of office, independent of the political ebb and flow. While this may render the post less attractive to the ambitious, it will make it more acceptable to the man with an earnest desire to serve the mining industry to the very best of his ability.

So we dismiss the dream of a Mining Department; the near reality of a Bureau will suffice for the present and when the new organization shall have proved itself useful and comprehensive, it will be time enough to revert to the larger idea. There will be difficulty in getting fit men even for the smaller range of activity, for untrained men and politicians are not likely to use their authority wisely and any bureau must depend for good service mainly on its personnel. In this respect, the Geological Survey is now well equipped, despite the allurements of the financial and industrial corporations, which have absorbed so many first-rate scientific investigators.

The new bureau will be mainly technological. First will come the investigation of explosives and the prevention of explosions, as well as other accidents such as have occurred with distressing frequency of late in coal mines. It is likely that the Fuel Testing Plant of the Geological Survey may be made the nucleus for further technological studies and prepare the way for laboratory investigations of a varied character. This is a part of the program for which we have no liking, believing that there is no need to trespass upon private initiative or ask the Government to do what can be done by the professional men to whom such work is a means of honorable livelihood. The lessening of waste, the prevention of accidents, the investigation of resources neglected by private or corporate enterprise, the regulation of conditions underground—these are among the duties fairly within the scope of the Bureau. And there are two more, namely, statistics and labor problems. We know that we offend our Survey friends whenever we attack their performance of statistical work. Not that the results are depreciated, for we hold that it is done better today than ever before, but we insist that the special training and particular aptitude of the geologist makes it desirable that he should be investigating ore deposits instead of chronicling the product of the mine and smelter. It is a human frailty for men to desire success outside of their particular vocation; but despite the excellent work done by Messrs. Lindgren, Graton, and Boutwell in the compilation of statistics, we still begrudge the time that might have been devoted to the elucidation of rock structure and ore occurrence. It is probable that many of our readers share this regret. So we expect to see the statistical work of the Survey transferred to the Mining Bureau and the literature of geology correspondingly enriched by the men relieved of these duties.

Labor problems are always with us, and they increase in complexity. The officers of the Mining Bureau ought to co-operate with the Labor Commissioners of the different States with a view to investigating the causes of unrest and collecting the facts upon which legislative action may be based. The incident at Goldfield gives point to the need for Federal aid. It should be possible to gather facts useful alike to the operators, the labor unions, and the legislators, and beyond these representatives of special interests, it should be possible for the Bureau of Mines to submit such authentic data as will enable the public at large to form a correct opinion and thus become an intelligent force in the settlement of disputes. There are other matters suggested by the presentation of the bill for creating the Bureau of Mines, but they may well be left for a later occasion. At present, the two things to be kept in view are not to impair the usefulness of the Geological Survey and to avoid any trespass upon the province of the practising engineer.

By the Way.

The legislature of the State of Nevada is in special session, convened for the purpose of passing a bill to create a constabulary intended to take the place of the troops, which are to be withdrawn from Goldfield.

The report of the three commissioners sent by the President to Goldfield, Nevada, for the purpose of investigating conditions, has been filed at Washington.

The report says the conditions did not support the general allegations in the Governor's request for troops, nor were his specific statements established to any such extent as to justify his use of these statements for the purpose of getting Federal troops.

It concludes with this recommendation: "But we must firmly believe that upon the assembling of the Legislature, or within a few days thereafter, the troops should be removed, regardless of any request for their retention, that may be made by either the Legislature or the Governor of Nevada, it being the essential that the State of Nevada shall understand the situation completely; shall recognize the fact that there will at that date be thrown upon it, and it alone, the primary responsibility of keeping order, and that, recognizing this responsibility, it may take such action as is the duty of the State and as will be sufficient in the premises."

In his letter to Governor Sparks, after reviewing the steps so far taken in the Goldfield mining trouble, the President continues: "I have just received the report of these three gentlemen (Murray, Smith, and Neill), which sets forth in the most emphatic langnage their belief, after a careful investigation on the ground, that there was no warrant whatever for calling on the President for troops and that the troops should not be kept indefinitely in Goldfield. The report further states that there was no insurrection against the power of the State at the time the troops were called for; that nobody supposed that there was such an insurrection, and that none of the conditions described in sections 5297-8-9 of the Revised Statutes as warranting interference by the Federal Government existed, and that the effort was and is plainly an effort by the State of Nevada to secure the performance by the United States of the ordinary police duties which should, as a matter of course, be performed by Nevada herself."

The report further says: "There is absolntely no question that if the State of Nevada and the county of Esmeralda exercise the powers at their disposal they can maintain satisfactory order in Goldfield; that so far these authorities have done nothing but rely on Federal aid, and their attitude now is expressed by that of refusing to do anything and desiring to throw their own burdens on the Federal Government for the maintenance of those elementary conditions of order for which they, and they only, are responsible.

"The signers of the report express their conviction that the troops should remain in Nevada until the assembling of the Legislature, so as to preserve the *status quo* in order that the Legislature may deal with the situation as it exists, but that shortly thereafter the troops should be removed.

"I agree with the recommendations of this report, of which I inclose a copy, and shall act accordingly. Unless it can be shown that the statements of the report are not in accordance with the facts, it will be incumbent upon the Legislature of Nevada when it convenes itself to provide for enforcement of the laws of the State. The State of Nevada must itself make a resolute effort in good faith to perform the police duties incident to the existence of a strike."

As the operators' association had instigated the call for Federal aid, the commission, on reaching Goldfield, allowed its connsel to present the operators' side of the case fully. This occupied five days. At the end of these hearings, the report says: "Inasmuch as we were by this time satisfied that the mine operators had not in any particular established a case justifying either the bringing or the retention of the troops, we did not deem it necessary to take any extensive evidence on the other side, and the hearing was substantially closed with a brief formal interview with the committee from the miners' union."

Reviewing the conditions leading np to the present strike and since the strike began, November 27 last, the report draws this conclusion: "The action of the mine operators warrants the belief that they had determined upon a reduction of wages and the refusal of employment to members of the Western Federation of Miners, but that they feared to take this course of action unless they had the protection of Federal troops, and that they accordingly laid a plan to secure such troops and put their program into effect."

When the troops arrived the mine operators issued a statement in which they indicated a reduction in miners' wages from $5 to $4 a day, also their intention not to employ miners who belonged to the union. The report adds: "While this cut in wages and refusal to employ members of the Western Federation of Miners was not announced until after the arrival of the troops, every indication confirms the belief that such action was in contemplation before the arrival of the troops, was part of the general plan of the mine operators to establish their independence of the union, and that the coming of the troops was expected and urged by them to make such a plan feasible."

Conditions at Goldfield, the report asserts, did not justify calling for the troops. The single case of the unlawful use of dynamite, which failed to accomplish any damage, was surrounded by such circumstances, the report says, as to raise a reasonable doubt as to the genuineness of the charge that members of the union were responsible. The great bulk of the testimony of the operators tended to show, according to the report, not the existence of past or present disorder, but the possibility of future disturbances should the troops be withdrawn. This view was held by many men of almost all classes, bnt was based on the changed conditions since the troops had arrived—namely, the declaration of the operators reducing wages and refusing to employ nnion men. As to the refusal of the operators to employ union men, the report sets forth a statute of the State prohibiting such discrimination. The commission expresses itself as satisfied that throughout the miners' union there are not over a few hundred men of dangerous type, while the great majority—probably three-fourths of the membership—were conceded to be men of law-abiding tendencies. By permitting their organization to be managed and controlled by men of violent tendencies the union as a body has thus laid itself open to the reproach of being a vicious organization.

"In view of the foregoing facts, we believe there is considerable danger that serious disorders will be attempted if the troops be withdrawn and the mine operators insist on carrying out their publicly announced policy. But if a handful of men have controlled the Goldfield miners' union and committed the organization to indefensible policies and practices, it is no reason why the county of Esmeralda and the State of Nevada should tamely submit to the domination of this same group and should not assert their anthority and power and enforce respect for law and order without support of Federal troops."

Personal.

ALLIENE CASE is here from Nevada.

S. SYKES, of Johannesburg, is at Denver.

S. SERGEANT NEWBURY has returned to Denver from the East.

C. F. NOURSE is now at Kyshtim, in the government of Perm, Russia.

G. M. HILLARY has an office as mining engineer at Chihuahua, Mexico.

N. C. GROCH has left San Juancito, Honduras, and is at Sandusky, Ohio.

RUSSELL T. CORNELL, of New York, is in Sonora, Mexico, on professional work.

JOHN HERRON has been on a visit to Palo Alto. He has returned to El Oro, Mexico.

WM. A. FARISH, JR., has opened an office as mining engineer at El Paso, Texas.

W. H. PAUL is general manager for the Dolores Mines Co., at San Isidro, in Chihuahua.

C. A. PRINGLE, manager of the Calera mine, in Durango, Mexico, is visiting his home at Oakland.

R. M. ATWATER, JR., is now manager for the Black Mountain Mining Co., in Sonora, Mexico.

CHARLES D. KAEDING was in San Francisco for a few days, and has returned to Goldfield, Nevada.

J. W. BRYANT, manager for the Tyee Copper Co., passed through San Francisco on his way to Sinaloa, Mexico.

GEORGE J. GRAHAM is general manager of the Aztec and Mercer San Rafael mines at Ameca, in Jalisco, Mexico.

ALBERT BURCH has gone to the Old Signal mine, in Mohave county, Arizona, where he is directing operations.

E. C. MUSGRAVE, manager for the Deer Lodge Con. Mines Co., in Montana, is recovering from a severe attack of pneumonia.

H. A. SHIPMAN and R. J. GRANT have joined forces under the name of Shipman & Grant, with offices at 520 Ernest & Cranmer Bdg., Denver.

H. L. CHARLES has resigned as general manager for the Bingham Con. Mining & Smelting Co., at Salt Lake, the smelter having been closed down.

BENJ. H. LOEB has resigned as metallurgist for the Reforma Co., of Campo Morado, in Guerrero, Mexico. He is now at the American Club, in Mexico City.

WILLIAM A. POMEROY, on account of ill health, was compelled to resign as manager for the Palmarejo & Mexican Goldfields Ltd. and is now at Palo Alto, California, having recovered from the effects of malaria contracted in Mexico.

ROBERT H. RICHARDS is approaching the completion of his additional volume on 'Ore Dressing,' and has four assistants and part of the time two stenographers at work upon it. He hopes to go to press in the late spring or early summer.

WILLIAM B. FISHER, who for the past two years has been general superintendent of mines for the Federal Mining & Smelting Co. at Wallace, Idaho, has been appointed manager for the Salt Lake Copper Co., with headquarters at Salt Lake, Utah.

J. E. SPURR has made a renewed arrangement as consulting geologist and engineer for the Guggenheim interests. On account of the advanced degree of progress reached in the geological surveys and examinations of the Guggenheim properties he will in the future be able to devote some time to other work.

Obituary.

L. H. WHEELER, superintendent of construction in the Boston Consolidated mill at Garfield, was accidentally killed by the bursting of a steam-pipe in the new plant early last week. Mr. Wheeler has trying out the machinery of of the plant just prior to putting it into regular operation.

Publications Received.

'Half a Century of Rope Making' is the title of a handsome booklet issued by the A. Leschen & Sons Rope Co. of St. Louis, Mo. Fifty years ago, in St. Louis, Adolph Leschen began in a small way to manufacture hemp or fibre rope. Today the great manufacturing plant of the A. Leschen & Sons Rope Co. covers thirty-three acres. Four branch houses and twenty-eight agencies handle the product of the works, which is sold not only throughout the United States and Canada, but in all of the South American republics, Mexico, Cuba, the Philippines, South Africa, Japan, Turkey, Egypt, India, and Russia. In addition to a sketch of the history of the company, the booklet contains a finely illustrated description of the wire-rope tramways and cables for other uses manufactured by the company.

General Mining News.

ARIZONA.

COCHISE COUNTY.

Announcement has been made by the managements of the principal mines in the Warren district that the employees will be paid in currency this month; this will cause the disappearance of the clearing-house certificates and denominational drafts that have been used in the district for a number of weeks.—— It is reported that an orebody carrying 15% copper has been found at the 750-ft. level which connects with the Junction shaft of the Bonanza Circle mine.——An orebody over 60 ft. wide has been found in one of the cross-cuts on the 1200-ft. level of the Hoatson mine; in another opening ore carrying 13% copper has been found.—— At the Copper Queen smelter an additional furnace and one converter were to be put into commission on Jan. 10; this would mean the employment of about 15% additional force.—— Work will soon be resumed at the Swisshelm gold mine; the rumor that this property was sold last week has been denied by the owners, W. K. Meade and Ben Heney. It is said that the Western Mines Development Co. about a year ago offered $250,000 for a 60% interest in the property, but the offer was refused.—— At the Claire mine, near Wood canyon, six men are employed, but the force will be increased as soon as buildings now being erected shall have been completed. It is expected to have the first carload of ore ready for shipment in two or three weeks. The new adit is now 170 ft. long, and exposes a pay-streak from 18 to 22 in. wide.—— Litigation over the Sullivan mine, which has prevented work at that property for nearly two years, is at an end; the Duluth-Chiracahua Development Co., which has purchased the mine, is expected soon to begin development work.—— At the Virtue mine operations have been suspended.

GILA COUNTY.

Recent development work at the Iron Cap mine of the National Mining Exploration Co. has given an encouraging result. On the 450-ft. level a drift was begun on a vein that had been cut 600 ft. from the shaft; the vein at that point had been leached, but the drift has penetrated good-grade ore.

GRAHAM COUNTY.

A good body of low-grade copper oxide ore has been found at the Lafave mine, which belongs to the Chase Creek Copper Co.; the new adit is 200 ft. long.——At the Gold Belt mine the shaft has reached a depth of 260 ft.; prospects for the development of an immense body of copper ore are said to be flattering. A carload shipment of ore made recently to the Shannon smelter averaged 18% copper.

MARICOPA COUNTY.

It is reported that Grant Busick, Andrew Joice, and J. A. James are sacking high-grade gold ore at their claims about six miles east of Harqua Hala. The ore is only 4 to 6 in. wide; two or three tons of it have been taken out.——The old Harqua Hala mine has just been put in good condition for stoping ore; at the mill 20 stamps are crushing ore from the Golden Eagle mine and 10 stamps are working on ore from the Harqua Hala mine.

MOHAVE COUNTY.

Although the Gold Road mill is closed, regular shipments of bullion will be made from the property; this bullion will be secured by letting a weak cyanide solution flow over the large dumps and pumping back the percolating water into zinc-vats in which a high recovery of gold will be made. The proeess has already yielded a big bar of bullion. The cost is said to be only a few cents per ton of water handled.——At the mill of the Idaho-Columbus Mining Co. at Cerbat, the roaster and electric separator are working well.——It is said that at the School Marm mine in the Chemehuevis range, E. Frankforter has found the ore-shoot from which much rich gold ore was taken several years ago. ——R. R. Gamey has gone to Los Angeles to purchase machinery for the Gladstone mine at Chloride.

PIMA COUNTY.

Judge Campbell has handed down a decision in favor of Paine, Webber & Co., of New York, in the sum of $272,299.04 against the Copper Bell Mining Co.; the money had been advanced to the latter company by Du Parquet, Huot & Moneuse for development work, and minority stockholders sought to prevent the assignment of the note to the plaintiffs in the action.——The directors of the Twin Buttes Mining Co. have resolved to resume work on their property; 30 or 40 men were to begin work on Jan. 10, and the number was to be increased as rapidly as possible to about 200. William M'Dermott is manager.

PINAL COUNTY.

The smelter being built at Sasco will soon be ready to be blown in. A new concentrating plant is also being constructed; it will be completed in about three months.——Two Keystone drilling plants have been received by the Ray Consolidated Copper Co.; they will be put in operation at once at the Ray mine.

SANTA CRUZ COUNTY.

The Four Metals Mining Co. is planning to further develop the Hillside mine by driving an adit and sinking a winze.——The San Miguel Mining Co., which is operating the California mine, near the Sultana mine, is planning to erect a quartz mill; large bodies of ore are reported blocked out in the mine.

YAVAPAI COUNTY.

Plans are being formulated to pay off the indebtedness in Arizona of the Arizona Smelting Co.; this is to be the preliminary step toward reorganizing the company and resuming operations at the Humboldt smelter.

CALIFORNIA.

AMADOR COUNTY.

In the Fremont mine, the shaft will require re-timbering from the 400 to the 850-ft. level because of a fire; this will require three months. When finished an attempt will be made to remove the debris to get at the bodies of the 11 men who perished at the bottom of the shaft.

EL DORADO COUNTY.

A rich vein of quartz ore is reported to have been found in the Red Hill mine in the Aukum district.——A test run of 100 tons of ore from the Vivian mine has given good results.——Wm. Craddock has driven the Vulture adit over 300 ft.——At the Dormody mine in the Green Valley district two engines have been installed.—— W. C. Covert has bonded the Morey quartz mine in the Grizzly Flat district and will start development work at once.——Work has been resumed with a full force of men at the Sherman mine. ——Lumber is being hauled to the Julian mine in the Pilot Hill district for the new mill which is to be erected soon. ——At the Shamrock-Lipton mine in the Greenwood district ore rich in sulphides has been developed; the company intends to sink several hundred feet deeper on the vein.—— H. H. Laederick is developing a mine in the Greenwood district for Mrs. De la Montanya.——Lee & White are pushing work at the Gilbert mine with encouraging results.

INYO COUNTY.

The Ubehebe Lead Co. is developing several small orebodies at its mine in the Ubehebe district. On the Wedding Stake claim the adit has a face of lead-silver ore; on the Cora claim a 3½-ft. vein of lead ore has been found.—— At the Emerald and Valley View mines, J. P. Hughes has found ore rich in gold, silver, copper, and lead.——At the Salsberry mine a contract has been let for the driving of an adit 500 ft. long.——The Keane Wonder mill has yielded $16,000 as the result of two weeks' run on ore from the Keane Wonder mine; the mill is now treating 75 tons of ore per day, the ore varying in value from $12 to $25 per ton. ——The Greenwater & Death Valley Copper Co. has let a contract for additional sinking of its shaft; it is intended ultimately to reach a depth of 1600 ft.——H. T. Whitworth intends soon to begin developing the Surprise group of claims in the Coso range; mines were worked there by slaves about 1860.——At the Good Hope mine near Skidoo eight men are at work; Edward Hamlin is superintendent.

KERN COUNTY.

A company has been formed in Los Angeles to work the Cottontail placer mine, in the Red Rock Canyon district. Pumps of large capacity will be installed and an effort made to sink shafts to bedrock. Dry washing machines, operated by gasoline power, have been tried on the ground, but the subsoil was found to contain too much moisture for good results; it is now hoped to develop enough water for sluicing purposes.——The Yellow Aster mine and mills are working to their fullest capacity; the supply of water is abundant.——Barney Ostick is keeping a little mill running on ore from the G B mine; the orebody is 5 ft. wide.

MARIPOSA COUNTY.

The 3-stamp mill recently erected at the Eureka and Excelsior mines about seven miles from Mariposa was started on Jan. 7 to crush about 200 tons of ore; assays show this ore to be of high value. Several men are employed at the mines.—Quite a number of small gold nuggets were found on the streets of Hornitos after recent rains; the largest reported weighed nearly an ounce.——A renewal of mining activity along the Merced river because of the building of the Yosemite Valley railroad has resulted in the discovery by Eganhoff Bros. & Kuhn of a vein a foot wide, which is said to carry $100 to $200 gold per ton; a 10-stamp mill is to be erected. A flume is being built to develop water-power and later an electric plant will be installed. ——Extensive improvements are being made at the Mountain King mine.

NEVADA COUNTY.

(Special Correspondence).—At a recent meeting of the Bear River Con. T. Co. the old board of directors was re-elected; it decided to continue active work at the Bear River mine. The adit is in 200 ft. and will be continued to a length of 500 ft. Four large veins have been encountered since the company has commenced operations. When the 500-ft. point is reached cross-cuts will be run to develop the veins.——The Central shaft has intersected a large vein of excellent ore. Considerable virgin territory is being opened up, and an immense quantity of ore has been developed in the upper workings.——A splendid body of ore has been encountered in the Golden Gate mine by W. P. Martin and associates; the shaft is being sunk to greater depth.—— A limited amount of development work is under way at the old Perrin mine.——Good ore is being developed in the Oustomah mine; several men are employed and the mine is looking well.——The mines in the Washington district have been meeting with difficulty in getting water-power since the late storms. Heavy frosts and snows blocked the ditches, forcing the Grey Eagle, Yuba, and other large producers to suspend. Late warm rains have thawed things out and a plentitude of water is now assured.——Considerable placer mining is going on through the county and the season promises to be a notably successful one. Heavy rain in the valleys and much snow on the mountains has insured a sufficient water supply for the season.

Grass Valley, Jan. 13.

The December clean-up of the Delhi mine was the largest of any month since the mine came into the possession of the present company. Everything is running smoothly and the mine is again on a paying basis. Hamilton Eddie is superintendent.——Operations have been suspended at the Alaska mine at Pike City until the arrival of a new electric pump.——At a meeting of the Midas Gold Mining Co. on Jan. 6, arrangements were completed for installing the necessary machinery to sink a shaft to a depth of 600 ft.; the machinery includes a 50-hp. boiler, 30-hp. engine, hoist, and a 4-in. pump. Concrete foundations will be constructed for the heavy machinery.——The South Yuba M. & S. Co. reports that it has developed a 50-ft. vein of valuable copper ore in No. 6 adit of its mine; the directors have decided to drive No. 7 adit from near the bank of the river, thus opening the vein at a great depth.——The Cold Spring Quartz & Channel Mining Co. is operating the Cold Spring drift mine and the Buckeye quartz mine; the latter has recently been unwatered, and surveyed for the purpose of putting it on a steady producing basis. New machinery has been added to the Buckeye mill to enable it to handle a liberal tonnage of ore.——Some good ore is being taken out of the Norambagua mine, where stoping is going on steadily on the north side of the shaft; it is expected that it will yield $60 per ton at the mill.——A 7-ft. lode has been found in a cross-cut at the Arctic mine, near Canyon creek.——A lawsuit is in progress between the Government and the Central Pacific Railroad Co. to set aside a patent to a section of mineral land near Cisco. The land has two mills on it, and miners and prospectors are testifying that the ground is heavily mineralized.——Sinking at the Kenosha mine continues without interruption; the shaft has passed through what the old miners term the 'hard bar' and has penetrated much softer ground. Geo. M. Root is manager.——The break in the North Bloomfield ditch, which caused a temporary shutdown at the Union Blue gravel mine at North Bloomfield, has been repaired; work was resumed at the mine on Jan. 8.——At the Lincoln mine, near Little Deer creek, the shaft is 80 ft. deep and sinking continues; at a depth of 65 ft. a drift was started east on the vein; it exposes an orebody about 11 in. wide in which gold can occasionally be seen. ——Considerable interest is manifested in the discovery of an antimony lode on the Robert Johnson ranch, five miles south of Grass Valley. It is claimed that it has been traced at the surface for a distance of two miles and that the outcrop is wide. Numerous prospect holes are to be sunk to

determine the quality of the ore.——The crushing of 100 tons of ore from the 500-ft. level of the Idaho-Maryland mine has been completed; the results were quite satisfactory. The ore has a width of 18 in. Bray Wilkins is general manager.——Timothy Lyon, of Forest Springs, has sunk a shaft 32 ft. deep on his New Granada claim; it exposes a vein that is 3 to 10 in. wide at the surface but increases in width in going down. It is said to carry from $18 to $50 gold per ton.

PLACER COUNTY.

(Special Correspondence).—The Morning Star drift mine at Last Chance is being cleaned and the old adit repaired preparatory to the resumption of mining.——At the Placer Gravel drift mine 15 men are taking out gravel from both ends of the channel deposit on this property.——The Home Ticket Co. has 12 men blocking out gravel at its drift mine in the Last Chance district.——At the Rublin quartz mine five men are driving an adit on the vein; some good ore is exposed. Snow and ice prevent the operation of the 2-stamp mill.——At the Deadwood drift mine two men are working. ——The 10-stamp mill at the Herman mine is being operated; the machinery for a new power-plant has not all

arrived.——Baird & Partner are working their placer mine in El Dorado canyon.——The Imperial Mining Co. is operating its hydraulic mine on the North Fork of the Middle Fork of American river.——The Three Queens mine at Forest Hill is being systematically developed; some good ore has been found.——At the Gray Eagle mine near North Star the old adit is being repaired.——Joe Bruner and associates are working the Old Drummond mine; at one time this property produced rich ore.

East Auburn, Jan. 12.

SAN BERNARDINO COUNTY.

It is stated that many prospectors and others are hurrying to the site of a new gold strike in the desert country near Manvel. The discovery of a vein the ore of which assays $2200 per ton is the cause of the stampede. Many people have left Needles and Searchlight in automobiles, buggies, and wagons, and on bicycles and burros.

SHASTA COUNTY.

Two carloads of chromite are being prepared by C. F. Dougherty and D. C. Brown at their mine near Castella for shipment to Valley Springs in Calaveras county, near which there is a copper smelter; the chromite is used for lining the four furnaces. The Mammoth smelter at Kennett also receives chromite from the same mine.——At the Midas mine 70 men are employed and the camp is in a flourishing condition.

The new furnace at Heroult is about ready for continuous operation; it is about 20 ft. high and about 10 ft. square and is in the form of a regular blast-furnace.——At the Milton mine in the Lower Springs district, a good orebody has been found in a 50-ft. cross-cut driven from the bottom of the shaft.

SIERRA COUNTY.

Gravel said to contain $200 gold per carload has been found at the Telegraph drift mine. It was opened at a depth of 22 ft. below the main adit. Electric power is being used to haul the cars. The gravel is about 3 ft. thick and as the work progresses it is widening.

SISKIYOU COUNTY.

The Champion Group Mining Co. has purchased the Granite mine on Humbug creek from Bird & Grant and J. E. Harmon; the new owners have several men employed and intend to increase the working force within a short time.——A statement appearing several times in the local press that the Morrison-Carlock mine is closed down is not true.——It is announced that the owners of the King Solomon mine near the South Fork of Salmon river will build a 50-stamp mill if the county will extend a wagon road from the Black Bear mine, a distance of seven miles.

TRINITY COUNTY.

The adit under construction at the Union Hill mine, it is estimated, will be completed in six weeks and then the hydraulic mine will be operated to its full capacity.——Joseph Porter has been appointed superintendent of the Bonanza King mine and will make an inventory of the movable assets, but is not to accept service of any papers; the property is in charge of Supervisor Stoddard, as a keeper for Sheriff Boyce.——At the West Point mine near Deadwood, a body of rich ore was found on Jan. 11. It is over 2 ft. in width and has much gold in a free state. A small force of men has been employed at this property for five months. As soon as weather conditions will permit a boarding house, bunk house, blacksmith shop, and ore-bins will be constructed. Mark Manley is superintendent.

TUOLUMNE COUNTY.

The mill at the Arbona mine is about completed.——Four men are stoping ore at the Gross mine; the mill will be started this week for a month's run.—— E. Murphy of Columbia has a small crew of men working at the Minerva mine, at Italian Bar.—— A 5-stamp mill is nearly completed at the Gem mine, five miles above Sugar Pine, on the North fork of the Tuolumne river.—— At the Old Soulsby mine a pump is being installed at the 600-ft. level in the Davidson shaft.——John N. Lyon, Frank N. Hill, William Blackmar, and John Starr have taken a bond on a portion of the Lewis ranch, near Stent, and propose doing some mining development on it.

VENTURA COUNTY.

It is reported that the Frazier Mountain borax mine will be closed down shortly and probably not operated again before spring. The reasons for the shut-down are the severity of the winter, which makes it difficult to keep up the roads, and also the action of the larger borax companies, which is said to make it hard for the small mine operators to market ore at good prices.——The Columbia borax mine has been closed for more than two months.

IDAHO.

SHOSHONE COUNTY.

The adit of the Golden Winnie tungsten mine, near Murray, is now over 600 ft. long; six men will be kept working in it all winter. It is said that this adit develops a body of ore 200 ft. long and 5 ft. wide, and that this ore carries 12% tungsten. David Gross, the president of the company, expects to make a trip to Germany to negotiate with the Krupp Gun Works company for the disposal of the ore.——The Hecla Mining Co. closed its mine on Dec. 29 for an indefinite period. Of the 155 men who were employed at the mine 20 will be retained to install a large new air-compressor and hoist; this machinery will permit working at a depth of 3000 ft.——The 18,000-lb. transformer from the Kellogg station of the Washington Water Power Co. has been hauled to the Federal mine where it will be installed for the use of the Last Chance mine.——Ore, some of which assays 29% copper, has been found in the Copper Age & Edison mine, near Saltese; the adit is 500 ft. long and work on it will continue with two shifts all winter.

NEVADA.

ESMERALDA COUNTY.

The United States Circuit Court at Carson on Jan. 11 took up the matter of the injunction proceedings against the Western Federation of Miners. The affidavits read to the court tended to show that the union at Goldfield had been the prime factor in all the labor troubles of the camp since its discovery; they accuse the union of having countenanced the action of the high-graders and also of protecting them by its fight against the change-room system. On Jan. 12 it was announced in Washington that President Roosevelt had determined to withdraw the troops from Goldfield shortly after the Nevada Legislature begins its special session. On the same date the report of the committee which has been investigating conditions at Goldfield for the President, was made public. It condemns Nevada for yielding to the vicious domination of a small number of men of violent tendencies who control the union at Goldfield, and scores the mine owners for laying plans to secure the protection of the troops. The Legislature convened on Jan. 14, with nearly all the members present. It is likely that a bill petitioning the Federal Government to establish barracks in the State will be presented; there will also be a fight by supporters of Governor Sparks to establish a troop of rangers on the plan adopted by Texas. The Goldfield labor trouble is making little change from day to day, except that the mine operators seem to be making steady gains that presage ultimate success. The most important move during last week was the importation of 80 good miners from Park City, Utah, to work in the Goldfield district. They were so quietly recruited by George Wingfield that no knowledge of it reached the Goldfield union; consequently, when they arrived there were no pickets on hand; but on the following day 400 pickets swarmed to the hills and at every opportunity tried to get the men to quit work. The men from Utah were Federation men, but before embarking for Goldfield they signed an agreement not to become members of the Goldfield Miners' Union No. 220 or any other union as long as they are working for the company which has imported them. Manager Mackenzie of the Goldfield Consolidated Mines Co. says that there are a thousand men in Utah, all Federation men, who can be enlisted for the Goldfield mines. The local union is visibly discouraged over the developments, for it had boasted that the mine operators would be unable to get good miners to come into the district; but it seems to have been mistaken in the matter of the Utah men.

The Goldfield mines are again on a producing basis. On

Jan. 11 the Western Ore Purchasing Co.'s plant at Columbia was still closed, but the company was taking all ore offered and handling it at Miller. Since Jan. 1 it received 100 tons from the Florence-Annex lease, of an average value of $100 per ton, and from the Mohawk-Combination mine 60 tons of $50 grade. The Little Florence company shipped 1035 tons of an estimated value of $207,000 to Denver for treatment; this had been produced before the suspension of work due to the miners' strike. Since Dec. 12 the Combination mill has treated an average of 80 tons daily; the average value is placed at $40 per ton.——The Florence-Gem Leasing Co., which recently took over the old Watson lease on Florence ground, has opened ore on three levels; on the 50-ft. level the ore is medium-grade; on the 100-ft. level it runs up to $100 per ton; and on the 150-ft. level there is a 12-in. streak of ore that assays $628 per ton. It is supposed to be a continuation of the Jumbo lode, from which lessees took fortunes in the early days of the camp.—— The superstructure for the Florence mill is completed and the machinery is being assembled; the arrival of the machinery was delayed through its having been lost between Denver and Goldfield, and it will be at least three months before the mill can be crushing ore.—— Work on the properties of the Goldfield Consolidated Mines Co. is being gradually resumed; between 200 and 300 men are employed. Sinking is under way in the main shaft of the Mohawk mine as well as development of the orebodies on the lower levels. Operations at the Red Top mine were to be resumed on Jan. 11. Grading for the new mill was to be started several days later; a large force of men will be employed constantly from the time the first shovelful of dirt is thrown until the mill is completed.—— It is reported that in the Wasson adit of the Pittsburg-Silver Peak mine an orebody 2½ ft. wide and of an average value of $140 per ton has been found. On Jan. 10, 60 stamps of the mill began crushing ore, and it is expected that the entire mill will be in operation by Feb. 1; the cyanide plant will be completed shortly.—— In the Rawhide district, the lode on the Royal & Tiger group of claims has been traced, it is said, 2100 ft. At one point it is 12 ft. wide. The Robbins lease has an orebody 2 ft. wide that is said to carry $500 per ton; on the Packard lease there is an 18-in. streak of ore which, it is alleged, carries over 1000 oz. silver and 1 oz. gold per ton.—— On the Poor Boy claim 20 lessees are working; the shaft at the Montana lease is 50 ft. deep.——Assays from the latest strike at the Kearns lease on Balloon hill indicate very rich ore.

EUREKA COUNTY.

During the past five months large quantities of ore have been shipped from the mines of the Richmond-Eureka Mining Co. at Eureka to the smelter; plans have just been perfected for increased facilities for the handling of upward of 500 tons per day. The town of Eureka has been revived through the renewed activities in these mines.

HUMBOLDT COUNTY.

The Mazuma Hills Mining Co. has made its fourth shipment of high-grade ore; this was secured mainly in the course of development work in a winze and drifts connecting with the lower adit.——It is reported that a large body of ore of good milling grade has been found on the 150-ft. level of the Seven Troughs Eclipse mine; a milling test is being made on it and if the result is satisfactory, a mill will be erected on the property.

NYE COUNTY.

The ore shipments over the Tonopah & Goldfield Railroad for the week ending Jan. 9, as reported by the Western Ore Purchasing Co., aggregated 380 tons, divided as follows: Jim Butler, 41 tons; Tonopah Extension, 95; Midway, 203; West End, 41. The Tonopah company sent 3050 tons, the Belmont 800 tons, and the Montana-Tonopah 500 tons to the mills, a total of 4350 tons. The total output of the Tonopah mines was 4730 tons, of an estimated value (the shipping ore being valued at $50 a ton and the milling ore at $20 a ton) of $106,000.——Development work is progressing as usual at the Tonopah Extension mine; the north cross-cut on the 1050-ft. level is being pushed rapidly and good progress is being made in the west drift on the 600-ft. level.—— Work in the West End Consolidated mine is being confined to the stopes above the 400-ft. level and to the drifts and crosscuts on that level west of the shaft.——The North Star mine is yielding some shipping ore of very good grade.—— At the Manhattan-Virginia mine, cross-cutting the outcrop for the purpose of holding the ground free from claim-jumpers has demonstrated that the lode is from 12 to 15 ft. wide and that it carries sufficient gold to warrant ore shipments to local mills.——A regular daily output of 25 tons of ore is being maintained at the Ross-Nash lease on the Union No. 4 claim of the Union Extension Mining Co. Sinking has been interrupted by a voluminous flow of water, but as soon as pumps have been installed the shaft is to be sunk to the 115-ft. point.——Work at blocks 13 and 14 on Union No. 9 claim at Manhatten is confined at present to retimbering and straightening the 200-ft. shaft.; a steam-hoisting plant will be installed.——Preliminary work has been started for the erection of the Mayflower mill in the Bullfrog district. The contract for the machinery has been let. The process will be crushing by stamps, amalgamation, and cyanidation with agitation. The water which was encountered in the Mayflower shaft at a depth of 500 ft. will, it is thought, furnish an ample supply for all mill purposes.——J. E. Burch has decided to establish a custom milling plant in Rhyolite; the initial unit will have a capacity of at least 50 tons daily.——Taylor & Griffiths have let a contract to Bruce Crofoot to sink an additional 100 ft. to the 300-ft. shaft of the Alliance mine.——The Gold Center adit in Bare mountain is 500 ft. long; work on it is being pushed as rapidly as it can be done by hand.——Work has been resumed at the Taylor Bullfrog mine.——The Bullfrog Pioneer L. & M. Co., which recently secured a lease on the Bi-Metallic mine, is making arrangements to install a 25-ton cyanide plant and a 15-hp. hoist; it expects later to add an air-compressor plant. The lease is said to have developed

The Troops at Goldfield.

Montana-Tonopah Mine.

an immense body of ore carrying from $5 to $15 gold per ton. ——The Gold Bar mill is complete, locked up, and ready to run.——The branch of the Nevada-California Power Co.'s line, which is to carry electricity to the Gold Bar and Homestake mills, is nearly completed. Delay in starting the mill may be caused by the non-arrival of pumps for the water system.——At the Homestake mill excavating for the foundation is almost completed and the cement work is under way.——Work has been temporarily stopped at the Bullfrog Keystone mine pending a decision as to the best plan for future development.——The lessees at the Gibraltar mine are preparing to make another shipment of ore before long.——At the Golden Scepter mine at Rhyolite work has been resumed in the new adit which is being driven in the Hobo vein.——At the Badger lease on the Ramsay mine near Willow creek, a shipment of several carloads of high-grade ore is being assembled.——Preparations are under way for the erection of the Robinson custom mill at Midas. At Red Mountain, the Hercules Syndicate Mining Co. has had a force of miners at work for four months; the main shaft is now 60 ft. deep.——Freezing of the water in the pipeline of the hydraulic mine in the Round Mountain district caused a suspension of operations early in January, but work has been resumed. At the Congress mine, at Johnnie the old shaft has been cleaned out and driving has been started from the bottom.——The westward drift at the 200-ft. level of the Mineral Hill mine near Manhattan is in ore that yields gold in the pan; the drift will be continued at least 200 ft. farther before sinking will be undertaken.

STOREY COUNTY.

The Yellow Jacket mine is about to take on new life through the building of a mill to treat the ore. On the 1100-ft. level of the mine there is developed a vein from 10 to 18 ft. wide; assays indicate that it carries from $3.41 to $14.62 per ton, of which 9⅀% is gold. It extends downward as far as the 3000-ft. level, and some of it was extracted from the 1400-ft. level and sent to the Carson River mills; owing to a milling charge of $7 per ton, railroad freight, and the high cost of steam-power for hoisting, it was impossible to make a profit. With the Yellow Jacket mill on the ground, and with electric power, the ore can be profitably worked.—— At the Ward mine there is being constructed an annex to the main hoisting works to accommodate the engine from the Ophir; the shaft will be sunk to the 3000-ft. level.

WASHOE COUNTY.

Ore is being sacked by M. G. Churchwood and Charles F. Mitchell at their new mine about midway between Verdi and Reno. The lode is between porphyry and limestone, and consists of reddish-brown quartz carrying gold and silver to a value of about $30 per ton.—— The 2-stamp mill at Derby has been crushing ore from the Renegade mine at Olinghouse; 12 tons of the ore yielded $700 gold.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Mogul mill, which was rebuilt from a chlorination to a cyanide plant, using rolls and Chilean mills for crushing, handling the sand in vats and the slime by the Moore process, was put in operation about three months ago. It was designed to have a capacity of 300 tons per 24 hours, and it is interesting to note that the average capacity for November was 330 tons per day.——The Imperial Mining Co. is diligently pursuing work in the Dakota shaft on Bald mountain; the shaft has now reached a depth of 430 ft. but is not expected to penetrate ore until it is 500 ft. deep.——It is said that after two years of work, the Mariposa Mining Co. has found the vein for which it was searching and has developed a good body of ore.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence).—The Grant Consolidated Mining Co. has driven an adit about 500 ft. long at its mine; 45 ft. of it is in an orebody of which the hanging-wall is not exposed. The vein for which the adit has been driven should be reached at about 600 ft. from the portal.——Work has been temporarily suspended at the Copper World Extension mine; it is reported that a diamond-drill will be used for prospecting below the 300-ft. level.——At the Butcher Boy mine the working force has been increased; the adit has been connected with the shaft on the 100-ft. level. An ore-bin has been constructed and shipping of ore will be resumed shortly.——A steam-engine, boiler, and air-compressor have been installed at the Olentangy mine.—— Work has been resumed in the upper adit of the Bluffton mine; some good ore has been found.——The Molson Mining Co. has purchased new machinery for its mill.

Republic, Jan. 13.

STEVENS COUNTY.

(Special Correspondence).—The Ark group of claims has passed to a new company; a hoist and compressor plant have been installed. A new shaft is being sunk on a vein of ore containing gray copper and assaying $146 per ton. Several tons of copper ore are ready for shipment.——The Young America mine at Bossburg has been sold to a New York company and is to be reopened.——Work is to be resumed shortly on the Butte & Chief mine with a large force.——The adit of the Globe mine is being driven on copper-gold ore, interspersed with galena.——Development work has been resumed at the Trojan mine, under the supervision of L. Larsen.——The Viking Copper Mining Co. is planning to expend $10,000 for equipment and development of its claims three miles from Orient; it is intended to drive the present adit 500 ft. farther.——In the adit of the Paymaster mine, on Toulon Mtn., galena ore containing chalcopyrite has been unexpectedly found.——From the First Thought mine ore is being shipped; some of it runs as high as $100 per ton.——The Trophy Gold M. & M. Co. has let a contract to sink 50 ft. on the Wild Rose claim. ——Arrangements have been made to resume work at the Swamp King, a rich gold property northeast of Rockcut.

Republic, Jan. 2.

CANADA.

BRITISH COLUMBIA.

The Granby Consolidated M. & S. Co. has begun shipping ore over the railways at the rate of 1000 tons daily. About 300 men are employed at the mine; men are arriving in camp every day. On Jan. 2 two furnaces were blown in at the smelter, to be followed by the remaining six in due time, as the ore shipments are increased.——The Strathmore mine has been closed; it is likely that some diamond-drilling will be done on the property.——The Le Roi No. 2 mine at Rossland is increasing its shipments. The ore carries much gold and silver.——Another large orebody has been found at the North Star mine; from this mine there were shipped about 3000 tons of ore during last year.—— Operations at the La Plata mine near Nelson have been temporarily discontinued; there is a large supply of ore at the mine but the present prices of silver and lead are not tempting.——At the Richmond-Eureka mine the new tramway that is being built by the W. S. Riblet Tramway Co. is nearly completed; when it is finished, the company will be able to ship a considerable quantity of galena to the Trail smelter.——A new 80-hp. boiler has been installed at the Charles Dickens mine; this will make feasible the mining of ore on the lower levels. In a short time the plant will be handling 150 tons of ore per day, making 10 tons of concentrate. Ore is being shipped daily; 34 men are employed.——The ore shipments in the Cranbrook district for the week ending Jan. 4 were as follows: St. Eugene, 600 tons: Sullivan, 600.

YUKON.

The Yukon Gold Co. has begun putting on a full force of men for winter hauling in the Twelve-mile district. The trail is now first-class for freighting; 2500 tons of iron pipe, wooden staves, mess-house material, and other freight must be moved from Twelve-mile Landing before summer to permit rapid progress in the construction of the ditch which is to supply water for mining on Hunker and Bonanza creeks. In the Ballarat district 75 men and 60 horses have been busy handling lumber and it will be necessary to put on an additional 50 men.

Special Correspondence.

London.

Sodium Cyanide.—The Sulphide Corporation. — Poor Results. — The Cattermole Process and the Zinc Corporation. — Procrustian Methods.

The Cassel Cyanide Co., of Glasgow, is doing remarkably well with the manufacture of sodium cyanide. Cyanide manufacturers complain of the competition in their trade and of consequently decreased profits, and another maker in Scotland has been forced to go out of the business. The Cassel company, on the other hand, is able to show an increased profit. For the year ended September 30 last, the gross profit was £69,726, out of which £20,000 was written off for depreciation of machinery, buildings, etc., and £5526 devoted to administration expenses, leaving a net devisable profit of £44,200. Of this sum, dividends and bonuses amounting to £35,250 have been paid, the rate being 40% on the issued capital of £88,125. A year ago the dividends were £22,000, and the year before £17,250. The company has a reserve fund of £20,000, formed during the last two years out of profits, and the plant has been continually improved, also out of profits, so that the company stands in a sound position. It will be remembered that the name of the company has only recently been in its present form. Before 1906, for 22 years the company was known as the Cassel Gold Extracting Co. When the MacArthur-Forrest patents expired or became valueless in other ways, the attention of the directors was turned to the manufacture of cyanide. The details of the process adopted are not published, but presumably it is a process in which the cyanide products of blast-furnace gases are acted on by metallic sodium. The company has a working arrangement with the Castner Kellner Alkali Co., which makes metallic sodium electrolytically. It is interesting to note that the blast-furnaces in the Glasgow and South Scotland district use raw bituminous coal and their gases are of special value. The plants for the recovery of by-products are very extensive and probably the iron-masters obtain as large a profit out of their by-products as they do out of the iron.

One of the standing mysteries of the London mining and metallurgical world is the inability of the Sulphide Corporation to pay dividends on its ordinary shares. The company was formed in 1895 to acquire the Central mine at Broken Hill and the Ashcroft process for treating zinc-lead ores. It was floated by the Exploration Co. in Hamilton Smith's time, conjointly with Antony Gibbs & Sons, of London, and Gibbs, Bright & Co., of Melbourne. Later on the Ashcroft process was abandoned and about the same time the Exploration Co. handed the control to the Gibbs houses. The capital consists of 550,000 preference shares of £1 each, entitled to 10% dividend and an equal amount of ordinary shares of 15s. each. In addition there are £79,600 in debentures outstanding carrying 5% interest. The Central mine is undoubtedly a very valuable property. In fact, mining men who know the district consider it to be equal to the Proprietary. Large amounts of lead and silver are produced every year and profits are realized on the mining and smelting operations. The quantity of ore still in the mine and laid open by current developments is very extensive. But all the advantages of having such valuable ores are neutralized by the expenditure of gigantic sums from time to time on new plants of all sorts and on putting the mine into order. If it may be said without offence, the company suffers from the effect of the other interests of the controllers. Gibbs, Bright & Co. are the commercial agents of the company and as such make profits out of the business of the company in various ways. They are also financially interested in syndicates owning patents for treating zinc-lead ores and their judgment and the judgment of the directors and managers are naturally biased in favor of these particular processes. For some years the Sulphide Corporation has been saddled in this way with the Cattermole flotation process for treating the zinc tailing. The directors say very little about the results obtained by this process, but it is a matter of common knowledge that the recovery is far from satisfactory. The experience of the Zinc Corporation has shown this. It will be remembered that the latter company was formed by Bewick, Moreing & Co. and their friends to treat zinc tailing at Broken Hill. At first the Potter process was tried and abandoned. Then the plant was modified to the Cattermole principle. A very few weeks' experience was enough for Bewick, Moreing & Co.'s engineers, and this process was quickly dropped. It happens also that some of the Bewick, Moreing group have financial interests in the syndicate operating the patents, but they were wise enough not to force forward a process for their own interests when they found that the process would not give satisfaction to the shareholders of the Zinc Corporation. Instead of doing so, they experimented on still further new processes, and found that the Elmore vacuum plant would give far better separation of the zinc sulphides. Consequently, they recommended this process in place of that which they had originally backed, and a large installation is now on its way out. I would say, quite respectfully, to the Gibbs control: "Go and do likewise." It is always a mistake for directors or managers of a mine to have prepossessions and predispositions in favor of particular processes. It means that the mine has to be altered to suit the process. Procrustes used to cut off or elongate the legs of his guests so as to make them fit his bed. If the Gibbs control would cease trying to fit the mine to their processes and their other interests, it would be so much the better for the mine and for the shareholders.

Chicago.

The Interstate Agreement.—Adjustment of Wages in the Coal Regions. —Conditions in Illinois.—Mitchell's Successor.—Prosperity of the Coal Industry.—Mineral Output of Illinois.

As the year came to a close the principal question among mining men here was whether the Interstate Agreement is to be renewed. It will be remembered that the system of collective bargaining originated in Illinois, or at least was here first applied to the coal business in a large way. As the thicker and more cheaply mined coals of the central and southern parts of the State came to be exploited the operators in the northern or thin-vein fields began to feel the pinch of competition. At an opportune time the United Mine Workers came to the front with the proposition for collective bargaining, which involved the regulation of competition between districts by means of adjustment of wages. Later the same system was extended to neighboring States, the two-year labor contracts being based on an agreement made in a convention representing the miners and operators of western Pennsylvania, Ohio, Indiana, and Illinois—the so-called 'central competitive district.' In this convention the basing rate was fixed for each State and wages were raised or lowered from time to time. In Illinois the basing rate is for Danville, and in a later State convention it has been customary to fix rates in other districts of the State relative to the Danville rate; preserving the central idea of bringing about as nearly as possible fair competition between

the various districts. It required sacrifices to establish this system, which, on the whole, all agree, has worked fairly well. The Illinois operators in their perhaps over-eagerness to get the system going, practically gave up the chances for introducing machine-mining and for payment on any but a mine-run basis. For years they have been fighting to regain this ground, since changed conditions make pick-mining even more desirable than formerly. That a run-of-mine system of payment is wasteful and extravagant requires no argument.

In 1906 the Illinois operators refused to grant an increase of wages unless concessions were made on these points. The Pennsylvania operators, led by Robbins, of the Pittsburg Coal Co., refused to stand with them, made separate agreements with the men, and so the Interstate Agreement went to pieces. The various State organizations have, however, been kept up, and in Illinois, at least, the operators are probably better organized and prepared for a fight than they ever have been. The United Mine Workers have been trying ever since the settlement of the last strike to secure a renewal of the Interstate Agreement. While it is not now nearly so important as it formerly was, there are probably certain advantages to all concerned in having it renewed. Two weeks ago a meeting was held at Indianapolis to consider the matter, but no agreement was reached. The Illinois operators refuse to come into any new arrangement without some substantial concessions on the two points in dispute, and temporarily the matter is in abeyance. No one thinks, however, that it will be dropped, and while a guess now is a guess only, it seems likely that eventually the agreement will be re-established and the Illinois operators will win their coveted double scale permitting payment for screened coal.

The whole matter of the Interstate Agreement is more or less tangled up with politics inside the miners' organization. As is well known, Mr. Mitchell has declined to serve longer as president. His career has been a long and honorable one, and he has been a great steadying force in the industry. When recently he was recovering from a dangerous illness there was an outburst of congratulation from all sides, which was as genuine and spontaneous among the operators and the general public as among the miners. Mr. Mitchell's closest associates have been Mr. Wilson, now congressman and secretary and treasurer, and Mr. Ryan, of the Illinois local. These men are candidates respectively for the positions of president and secretary-treasurer of the national organization. They are strong men who, if elected, will follow in the wise footsteps of their leader. The opposition is headed by Mr. Lewis, now vice-president, who is regarded by the operators as a much more radical man and who, if elected, would probably materially disturb existing relations. It is too soon to say who is to be the winner.

Taken as a whole, 1907 has been an exceedingly prosperous year for the coal industry of Illinois. David Ross, secretary of the Bureau of Labor Statistics, recently presented statistics showing that for the year ending June 30, 1907, the production was 47,798,621 tons, as compared with 38,317,581 tons for the year ending June 30, 1906. For the calendar year of 1906 the production was 41,480,104 tons. If the same amount of increase was made for the last half of the year the tonnage for 1907 should run somewhat over 50,000,000, and that would probably again place Illinois in second place. The fall has been very busy and last summer was an unusual one, so that it is not unlikely that this will be the result.

The second big increase in the mineral output of Illinois in 1907 will be shown by the oil. These fields, which were only discovered in 1905, and which in 1906 produced 4,397,050 bbl., have had a remarkable development since. This production for 1907 will run somewhat over 24,000,000 bbl. The oil is of good grade, about 32 gravity, and sells for 68c. per bbl., so that this adds materially to the year's total. The remaining mineral industries of the State have done well, but there are no such remarkable increases as in coal and oil. One new portland cement plant has been built and several of the old lead-zinc mines near Galena have been reopened. The fluorspar mines have made their customary contribution and heavy building operations have made large demands on the quarries and clay pits. In general the year has been a good one, though as elsewhere there has been a distinct check in the last few months.

Rossland, British Columbia.

General Progress.—Mining at Rossland.—The Consolidated Co.—Le Roi.—The Boundary District.—Electric Installations.—The Slocan District.

Had the year which has just closed not been fraught with many circumstances adverse to the mining and smelting industry of British Columbia, the output for 1907 would have been an exceptional one indeed. The operating companies had to contend with a serious strike in the Crows Nest coalfield in the earlier part of the year and an almost continuous shortage of cars, both of these bringing about a scarcity of coke for the smelters and other fuel for the mines; and yet they have done well, for the output from the Yale-Kootenay district almost equals that of 1906, although the mines and smelters were only operating part of the time during nearly three months of the year. At Rossland a decided step forward has been taken by the mines. The Con. Mining & Smelting Co. of Canada has led the pace. They have acquired a large number of the claims adjoining their Centre Star-War Eagle properties, installed a 1000-hp. hoisting plant and greatly supplemented their electrical and air-compressing equipment. At the present time they are to a depth of 2000 ft. and have more ore in sight than ever before. The Le Roi Co. had no need to add to its already well-equipped power and hoisting plant. The principal work was the sinking of the main shaft from the 1450 to the 2000-ft. level and the exploration of the intervening ground by means of drifts, winzes, diamond-drill, etc. The mine is looking well. Le Roi No. 2 worked steadily and made money for the shareholders. The other properties did fairly well.

In the Boundary country the Granby people added materially to their smelting, hoisting, and ore-crushing machinery. The six crushers now in use at the mines have 42 by 30 in. receiving capacity and weigh 56½ tons. Their excellent air-compressing and electrical plant was not augmented to any notable degree. Steam is rather a waning power in this district. The power now used by all recent installations is electricity, which is generated at Bonnington Falls near Rossland, and carried to the Boundary by a heavy transmission line. The Granby people also acquired a number of claims adjacent to their Phœnix mines and now have enough ore in reserve to run their plant for 10 or 15 years. The Consolidated Mining & Smelting Co. (the stock of which is largely held by prominent C. P. R. men) has also taken over a large number of claims at Phœnix; a large air-compressor has been added and electrical locomotives for underground haulage on the Snowshoe group. It is expected that great headway will be made in 1908. The B. C. Copper Co. has gone ahead steadily and only recently found it necessary to increase its crushing plant by a 56½-ton crusher and a big compound air-compressor. The Mother Lode mine is looking well, with plenty of ore in reserve. The Dominion Copper Co. did

a lot of work during the year. They added to their smelter capacity, made it more up-to-date, and installed two compound air-compressors, electrically driven, at their Sunset and Idaho mines. They are at present closed down and have not been operating since the early autumn.

In the Slocan district, the famous St. Eugene, Canada's premier silver-lead property, has been operated steadily and has made lots of money for the Con. M. & S. Co. of Canada, by whom it is controlled. Incidentally, it may be noted that in addition to the properties at Rossland, Phœnix, and Moyie, the Consolidated Co. operates an up-to-date smelting and refining plant at Trail near Rossland. Fine gold and silver from these works are furnished to the Canadian Mint and are marketed in the United States and China.

The Sullivan group of mines and smelter at Marysville were run steadily during the year and did well. The smelting plant was brought up to a higher standard and a great amount of development work in the mines is planned for the early part of the present year. A. I. Goodell, who has spent the best part of his life in dealing with lead ores, is now in charge and it is reasonably expected that a good showing will be made. Great activity was shown among the smaller silver-lead prop-

Map of Part of British Columbia.

erties and the next couple of years should see many prospects blossom into producing mines. Ore shipments from the district ran as follows:

Rossland, gold-copper	283,340 tons
Boundary, copper-gold	1,148,337 "
Slocan-E. Kootenay, mostly silver-lead	185,857 "

The coal mines have been working steadily for the past six months, but several have recently closed down, temporarily. The principal mines, those of the Crows Nest Co., are working, as well as those of the International Co. The Granby company has just resumed operation after a shut-down of six or seven weeks. It is expected that the B. C. Copper and Dominion Copper mines will start to work again within the next six or eight weeks.

A couple of years ago the Canadian Government, to assist the lead-silver miners of this country, voted $2,500,000 for a bounty to stimulate the industry. The bounty was payable on a sliding scale; the higher lead went, the smaller the bounty.

Salt Lake, Utah.

Smelting Conditions.—Shipments from Tintic.—Lower Mammoth Co. —Uncertainty as to Future of Smelting Business.—Boston Con. Mill.—Silver King Coalition.—An Association of Mine Operators.

One Utah mining company posted a dividend during the past week—the Colorado; the amount was 5 cents per share, or $50,000. Although this company is one of the clients of the United States Smelting, Refining & Mining Co., recently ordered to cease shipments of ore, the directors deemed it advisable to share profits with stockholders. The treasury of the company is in a healthy condition. Production may not be resumed again until the new smelter of the Tintic Smelting Co. is ready, which will be in April. This smelter is being erected within a few miles of the mine, and the equipment is on the ground.

Ore shipments from the Tintic were a little larger last week, this being due to the heavy draught made on the Centennial Eureka mine of the United States Smelting, Refining & Mining Co., a portion of the ore being diverted to Kennett, California. The mines shipping and the respective amounts were: Bullion Beck, 4; Carisa, 2; Centennial Eureka, 44; Eureka Hill, 2; Mammoth, 29; May Day, 3; Tintic Iron, 4; Yankee Con., 3; Colorado, 4; total, 95 carloads.— —The shaft at the Opex mine has been completed to a depth of 1300 ft., and the management is exploring the various levels with encouraging results. This mine is owned largely by Salt Lake people; but F. Augustus Heinze is a shareholder. Many believe it to be one of the best mines in the Tintic district. The ore is similar to that of the Centennial Eureka mine.

In order to carry on development while the mine is not producing, the directors of the Lower Mammoth Mining Co. have called a special meeting of shareholders for February 5, at which time the proposal to increase the capital stock of the organization from 190,000 shares to 250,000 shares will come up for consideration. It is also proposed to issue $80,000 worth of convertible bonds. The Lower Mammoth mine is at Tintic and has been opened to a depth of 1800 feet.

The United States Smelting, Refining & Mining Co. is still operating its copper and lead smelter in the Salt Lake valley; but no ore is being received; it is probable, therefore, that within a few weeks, at the most, the plant will be idle. The plans of the company for the future are not known. It is believed that the lead smelter, at least, will resume operations soon after the shut-down. It seems unlikely that the Murray plant of the American Smelting & Refining Co. will be permitted to operate and the United States company denied the privilege.

The Boston Consolidated Mining Co. has a portion of its new mill at Garfield in operation. By the end of the month it is expected that at least three sections will be running on ore and giving treatment to 1500 tons per day. At the Boston Con. mine at Bingham about 250 men are employed.—— The New England mine at Bingham is still producing ore, notwithstanding the low metal market, and is continuing vigorous development. The Utah Apex has a large force on development; the Phœnix mill is nearing completion, and will probably be ready within a month. The mill will have a capacity of 200 tons. The Utah Consolidated management has mapped out a campaign of development. Just what will be done about the construction of a new smelter has not been decided, but the matter will undoubtedly be settled during the present month. The American Smelting & Refining Co., however, has been after Utah Consolidated ore, and the officers of the latter company have been approached on the subject. Unless the American will consent to a very favorable contract, there will be no change in the plans for the new smelter.

The Silver King Coalition Mines Co., of Park City, will have to make an accounting for ores extracted from the Arthur and Conkling claims. A suit has been filed in the Federal Court in which N. Treweek and J. Leonard Burch appear as plaintiffs, and allege the ownership of a three-quarters interest in the property, and that 10,000 tons of ore of the value of $40 per ton has been extracted, for which there has been no division of profits. The ore is alleged to have been mined and milled by the Keath-Kearns Mining Co., which has since been absorbed by the Coalition company. The directors of the Silver-King have passed the usual quarterly dividend, giving as a reason the unsatisfactory smelting and metal market conditions.—— A meeting of the ore producers of the State will be held at the Commercial Club in this city on the 15th inst., for the purpose of organizing a State association. In view of the recent effort of smelting companies operating in the Salt Lake valley to increase treatment charges on ore, mine owners are enthusiastic over the proposition of forming an association.——The May Day, Uncle Sam Consolidated, Victoria, and Grand Central Mining companies, all owning mines in the Tintic district, have passed the January dividends.

The directors of the West Mountain Placer Mining Co. are expected to post a dividend of $5000 during the week. This corporation derives its revenue from the lease of certain water rights and lands to the Utah Copper Co. in Bingham canyon.—— The Utah Copper Co. closed the year 1907 with a production of 15,000,000 lb. copper. In December the output was 3,000,000 lb., and the cost of mining 31 cents per ton.

Leadville, Colorado.

Annual Record.—Effect of Drooping Metal Prices.—The Yak Tunnel.—Zinc Ore Concentrators.

The official returns from the various mines of the Leadville district show a slight falling off in tonnage as compared with the previous year, but an unusual amount of development work was accomplished, which, with a restoration of prices, should give the district during the present year its old standing. The low prices for zinc and lead ores during the last two months has forced the large producers to curtail their output materially. The following is a summary of the various classes of ores produced in the district during the year 1907:

Kind of ore.	Tons.
Siliceous	119,000
Oxidized iron	123,400
Sulphide	233,500
Carbonate	39,600
Manganese	21,000
Zinc	136,000
Total	675,500

Among the principal producers are the following:

Company.	Tons.
Yak M. M. & T. Co	89,000
Ibex Mining Co	62,200
Western Mining Co	55,400
Midas Mining Co	80,800
A. Y. & Minnie	30,900
Iron Silver Mining Co	101,500
Morning Star Mining Co	37,000
New Monarch Mining Co	17,300

The products were as follows:

Gold	56,137 oz.
Silver	5,298,922 "
Lead	45,893,669 lb.
Copper	5,908,154 "
Spelter	71,152,400 "
Manganese	24,000 tons

Practically all the ores of the district were treated by the American Smelting & Refining Co., the Empire Zinc Co., the United States Smelting Co., and the Ohio & Colorado Smelting & Refining Co. The year witnessed an unusual advance in prospecting and development work. The Yak enterprise stands paramount. This company has extended its operations during the past year in various directions and is still extending its laterals at the rate of 250 to 300 ft. each month. The adit is at the present time over 2½ miles long; it has crossed the Ibex ground and is pushing toward the north. Among the laterals those into the North Moyer, White Cap, Belgian-Frenchman, and N. M. Fraction are among the most important to the Breece Hill producers. This company has adopted electric power and is furnishing a large number of producers in this and adjoining districts with power; however, its electric plant is now merged into the Central Colorado Power Co. During the year large mills were erected by the Leadville District M. & M. Co. and the A. M. W. Mining Co. for the treatment of zinc ores, the former to treat the Ibex dump and the latter the Adams zinc sulphides.

Chihuahua, Mexico.

San Toy Mines.—The Encinillas Co.—Sierra Mojada.—The Almoloya District.—Dolores.—Some News From Zacatecas.—The Benito Juarez Mines.

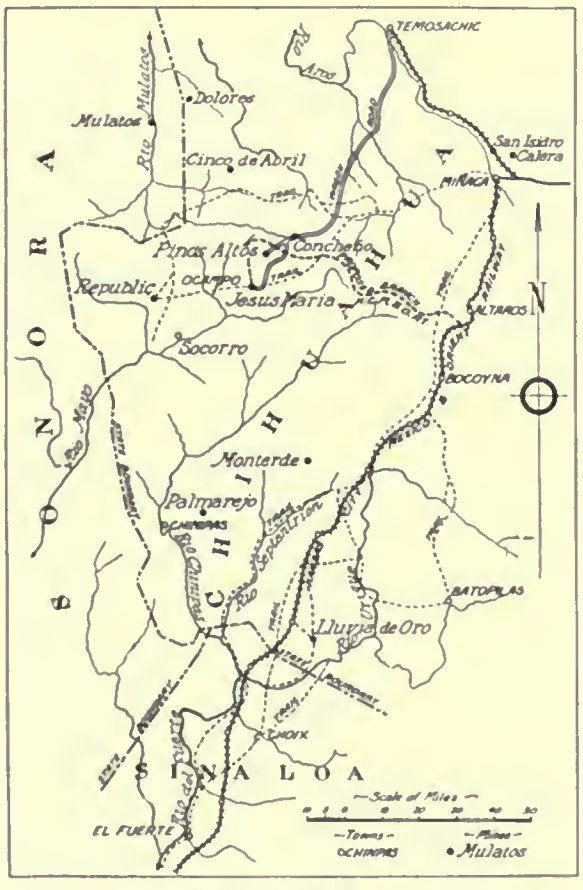
The San Toy mines, in the Santa Eulalia district, have increased their ore shipments from 200 to 400 tons per day to the Torreon smelter. The mines comprise the Galdeana and Juarez. L. A. Dockery of Chihuahua is mine superintendent, and J. P. Hutchinson is general manager.——The Encinillas Mines Co. is the owner of the smelting plant at Santa Rosalie. The company has acquired some mining properties in the Sta. Eulalia district, one of which is developed. Some new equipment has been added to the plant and it is announced that the furnaces are to be blown in soon. H. Thofern represents the French and English stockholders who control the concern. R. J. Morambert, formerly with the A. S. & R. Co., is superintendent.

The Sierra Mojada mines in Coahuila are producing about 8000 tons of ore per month, which is 2000 tons less than was being produced six months ago. The principal mines are those of the Cia. Minera La Constancia, managed by W. Hageman; those of the A. S. & R. Co., managed by W. B. Gates; those of the Cia. Metalurgica Mexicana, under the management of G. H. Carnahan. The Constancia ores are shipped to the smelter at Torreon, those of the Mexicana to its own smelter at San Luis Potosi. The ores of the Mojada district are of two classes: A lead-iron ore averaging 400 gm. silver per ton, 12% lead, 35% iron, and 20% silica; and a lime ore, carrying 800 gm. silver, 2% copper, 30% lime, and 20% silica. The latter class makes a desirable ore for the copper furnaces. The lead-iron ores are obtained at 100 to 300 ft. depth, the lime-copper ore from 400 to 600 ft. The lead blanket has a decided dip and as its strike is followed there is a gain in depth. The lime-copper ore occurs in the lime near the contact with conglomerate.

The Almoloya mining district is five miles from Baca station, the latter being between Jimenez and Parral. Among the properties there is the Cigarrero mine, belonging to a Mexican company, which has been mining and shipping ore for the last four years. It is said the profits in that time have amounted to P5,000,000. The workings extend to 1000 ft., the ores being silver, lead, gold, and copper, mostly oxidized. Shipments are made to the Monterrey smelter. The equipment includes a 3-rail incline tram extending from the mine, on the mountain slope, down to the base of the hill to the bins.

This is 4000 ft. long. The ore is hauled to the Baca station over the company's four-mile line of railroad.—— The Mexican Mines Corporation of Chihuahua is developing the Placeres group in the Almoloya district, employing 40 men. The work has reached 220-ft. depth. W. D. Pearce is superintendent. The Cia. Minera de Almoloya, in developing the Iguana group, has shipped a good tonnage of ore. The shaft is now 500 ft. deep and the intention is to sink deeper in the hope of striking the Cigarrero vein on its dip toward the Iguana. The ores of Almoloya present a variety. Besides lead, silver, and copper in an oxidized condition, there is said to be considerable of copper and zinc carbonates.

The properties of the Dolores Mines Co. are at Mineral de Dolores, in the northwestern part of Chihuahua. The camp is reached by traveling 35 miles over a new trail westerly from Madera, the latter being on the railroad of the



Map of Part of Mexico.

Sierra Land & Lumber Co., which connects with the Chihuahua & Pacific railroad at Temosachic. The Dolores company maintains an agency at San Isidro, a town and post-office on the Chihuahua & Pacific railroad. These are the gold and silver mines, opened by a 550-ft. shaft and a 1200-ft. adit. The latter intersects the shaft at the 350-ft. station. The hoist, air-compressor, and mill are being operated by steam, but plans are made for installing electric generators having a capacity for all purposes. An interesting fact concerning the engines, boilers, mill equipment, air-compressor, and pumps is that they were all built sectionalized and transported to this camp on pack animals. The mill consists of 15 stamps, 3 Bryan mills, 2 tube-mills, 3 Wilfley tables, and 7 agitating vats. The stamps crush the ore in a weak cyanide solution. The tables make an iron and copper concentrate, which runs high in gold and silver. In this way most of the copper is taken out of the pulp that goes to the agitating vats. The re-grinding by the Bryan mills and tube-mills is such as to make a product 85% of which will pass a 200-mesh screen. After cyaniding in connection with agitation and decantation, the slime is passed to Butters filters for withdrawing the solution from the solid material. W. H. Paul, the general manager, states that the mill yields an extraction of 93 to 96%. The gold and silver in the ore are about equal in value, making an ore worth approximately $50 per ton. This company has extensive timber rights, and roads have been built into the well wooded tracts. Recent improvements include a sawmill and a telephone line to the railroad at Madera. The company employs 700 men.

The Benito Juarez Mines Co., of the City of Mexico, has acquired and consolidated 30 mining properties in the Peñon Blanco district of Zacatecas, situated 10 miles southeast of Salinas. These properties have been operated for years by Mexican owners and their record of production is excellent. About half of these are on one mineral zone and the rest on another, striking parallel to each other through a country of limestone shale. The ore carries chloride and bromide of silver, accompanied by gold, some of which is in free state. This applies only to the orebodies above the water-level, which is about 400 ft. below the surface. Below the water-level the metals occur as silver sulphide, with gold, associated with pyrite. In the oxidized portion the silver is of first importance, while in the sulphides the gold is dominant. The vein is from one to ten metres wide. The deepest shaft on the property is 425 ft., with a 70-ft. winze from the lowest level. The worked-out chambers on this and other mines of this group show the ore-shoots to have been of great width and continuity. On the lower levels where the ore was untouched by former operators the vein structure is apparent. To the 450-ft. level the vein appears of quite uniform width and between well-defined walls. This has reference to the property that is now the chief centre of operations. There are other shafts and adits along the strike of the mineral belt, with numerous dumps of ore of milling grade, affording some idea of the extent of the development carried on at an earlier period; in fact, there are four or five dumps on the group that contain an aggregate of about 30,000 tons of ore which will pay to mill. Since July 1, 1907, this company has shipped ore of the value of P100,000, the result of development work. In this manner the output is paying for exploration and a considerable amount of surface improvements. The ore designated as shipping ore is said to carry 43.8 gm. gold, 1275 gm. silver per ton, with 0.6% iron, 14.2% lime, 71.6% silica, giving a gross value of P103 per ton. The mill-ore contains 32.5 gm. gold, 518 gm. silver, 1% iron, 11.3% lime, 68.8% silica, having a gross value of P62 per ton. It is estimated that the mill-ore on the old dumps will average P18 per ton. A mill is to be built on the property, to have the capacity of over 100 tons per day. Plans have been made and the contract for supplying the machinery will be let before this is in print. It will comprise a crusher, 20 stamps, belt-conveyors, hydraulic sizers, Wilfley tables, tube-mill, and cyaniding equipment. It is proposed to use cyanide solution in the battery. The method proposed has been well tested in an old mill on one of the properties. The mill, air-compressors, hoisting machinery, and other equipment are to be operated by electric power, to be generated at Salinas station. The plans also contemplate the building of an aerial tramway to convey ore from the various mines to the mill. The officers of the Benito Juarez Mines Co. are as follows: A. B. Carpenter, president; John C. Brennon, general manager; Engle Carpenter, secretary; E. P. Ryan, engineer. Dr. Philip Marvel, of Atlantic City, N. J., and Geo. W. Coles, of Philadelphia, are among the stockholders. C. O. Lundberg has just been made general superintendent.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

IN sinking very dry shafts a little water let down in the form of a spray just after blasting will aid in ventilation.

HARD TIMES have not depressed the radium market, the latest quotations being $3000 for the thousandth part of a gram.

THE breaking of a winding rope while raising or lowering persons happens very rarely; since mining was resumed on the Rand in South Africa in 1901 there have been only two such occurrences.

THE best preventive of the spontaneous ignition of coal is a small cylinder of compressed carbon dioxide fitted with a fuse plug melting at 200° F. A cylinder 1 ft. long and 3 in. diam. would be sufficient to fill the pores of 8 tons of coal.

THE cost of producing blister copper at the Mount Lyell mine in Tasmania during the half-year ended Sept. 30, 1907, was $3.704 per ton of ore; this was 24.46c. higher than in the previous half-year. The ore treated averaged 2.32% copper, 1.72 oz. silver, and 0.045 oz. gold per ton.

THE cost of mining coal in Montana and Wyoming has been roughly estimated at $1.65 per short ton, distributed as follows: Inside labor, 45c.; outside labor, 17c.; driving gangways and entries, 63c.; supplies, 17c.; preparation, 8c.; general expenses, repairs, and insurance, 14 cents.

MUCH trouble is caused in brazing by not using thoroughly fused borax. Dry borax does not answer, as it swells while brazing and makes the joint porous. The borax should be melted in a clay or iron crucible to a clear liquid, so as to drive off all water. Such borax will not swell when used for brazing.

WHERE the practice of a mill is rolls and cyanidation, the coarse gold may be extracted by running the sand over Wilfley tables (200 tons to 16 tables) and then reconcentrating the product on four additional tables. The product from this can then be placed in a clean-up barrel and pan, where the gold becomes amalgamated.

THAT underground waters are not necessarily all of meteoric origin is now recognized by geologists. Some may arise from the squeezing out of occluded water from igneous magmas as they cool and contract, but it has not yet been proved that such waters are given out in sufficient quantity to feed thermal springs or to form ore deposits.

TWENTY-FIVE stamps each of 1400 lb. are being added to the mill at the Witwatersrand Deep mine in South Africa, to be used instead of tube-mills for fine grinding. The concentrate from the 220 stamps of the present plant is to be returned from the spitzluten and re-ground in the mortar-boxes of the new stamps, which will have very fine screens.

WORK done by a dredge, excavating gravel on a placer claim, satisfies the law as to assessment work as to the location upon which the work is done, but this class of work done upon one location cannot be credited to adjoining locations, nor can the cost of the dredge be considered in estimating the amount of assessment work on the group of claims.

IN the gold mines of Orenburg, in Russia, a great quantity of timber is used in the underground workings. Drifts, cross-cuts, and winzes are all closely timbered, even when the rock is quite sound and hard. Close timbering with square sets seems to be invariable in the stopes of the Russian mines. It appears that the Russian Mining Inspectors require timbering in all underground workings, regardless of the nature of the ground.

IN the measurement of alluvial deposits, a cubic yard of ordinary gravel is usually estimated to weigh 3000 lb. The value is stated in cents of free gold per cubic yard, and the result is determined per yard of measured dirt and per yard of space excavated. The gravel has rarely less than 30% nor more than 45% of voids. If the pebbles have an average specific gravity equal to that of quartz (about 2.60) a cubic yard of the gravel would weigh from 2408 to 3064 lb., depending on the percentage of voids.

THE law does not restrict the number of claims that may be located continuously on a lode by an individual, nor does it limit the number of placer locations that an individual or an association of persons may make. An individual may make as many 20-acre placer locations or as many lode locations as he sees fit, provided, of course, that he makes a discovery on each, and otherwise complies with the Federal or State laws. This is the uniform rule throughout all the States, so far as we are advised. There is an exception in Alaska, made by local rules, limiting the number of placer locations that a locator may take on a given creek or bench.

THE breaking load of the ordinary one-half inch wire hoisting-rope, composed of six strands, of 19 steel wires each, and a hemp centre, is from 7 to 8 tons, and the safe working load is about one ton. If there is more cable on the drum than is in use, it should lie perfectly even and smooth on the drum. To accomplish this, when attaching the cable, wooden clamps are often put on the cable, to tension it as it is wound on. As these clamps groove rapidly, making an uneven tension, a better plan is to run the loop of the cable down the shaft, and attach a weight there, which will give a uniform load as the rope is wound up. A loaded bucket of the size generally hoisted makes a good weight, and can be temporarily fastened to the cable with a clip. If the rope is not tightly and evenly wound, it will jump as it changes direction, at each side of the drum, causing an excessive strain on the cable, and increasing the wear.

AN UNUSUAL METHOD for determining the cross-section of a river having rapids in which a boat could not be held, has been used at the Wabegeshik chute on Vermillion river in Canada. A fine steel wire such as is used for binding armatures of electric motors was attached to a 25-lb. lead weight. The length of the wire was measured and a transit set upon the bank close to the water's edge. The weight was put into the water on the opposite side in line with the transit on the cross-section desired. The lead weight was pulled across the river-bottom by the transit-man. Readings of its position were taken as often as desired. The distance from the weight to the axis of the telescope was determined by deducting from the total length of the wire the portion back of the transit. The vertical angle of the wire was read by the transit-man sighting at the point where the wire cut the surface of the water. These readings were plotted to scale and the cross-section of the bottom of the river determined as accurately as was necessary for the purpose. This was accomplished without danger and at small expense.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

History of Cyanidation.

The Editor:

Sir—In your issue of November 30 Mr. Philip Argall describes the Diehl process as practised at Kalgoorlie, and as I consider this account of the process to be somewhat misleading, I beg your permission, and the author's, to make a few remarks on the subject. In the first place, Mr. Argall states that the ore is crushed in batteries using dilute cyanide solution; also, inside and outside amalgamating plates are employed. As far as I am aware it is not at all desirable to use cyanide in the battery water, but in Kalgoorlie pure water is such an expensive item that it is found advisable to use the same liquid over and over again as much as possible; the return water contains cyanide and this must necessarily contaminate the fresh supply. With regard to amalgamating-plates inside the battery-boxes I may say that this is *not* the feature of the process, nor, as a matter of fact, do any of the batteries in West Australia that have big stamp-duties use inside plates. There are only two plants in W. A. that make use of the Diehl process, namely, the Lake View Consols and the Oroya-Brownhill, and in both of these the coarse crushing absolutely prohibits the use of inside plates. In addition to this, on the Lake View Consols there are no outside plates, the pulp going straight from the boxes to Wilfley tables. I am not certain if the same state of things obtains at the Brownhill, but I think it is so.

Mr. Argall says that the concentrates are roasted and amalgamated. This is quite right as far as it goes, but in actual practice the roasted concentrate is slimed in Wheeler pans into which quicksilver is fed, and the slime is agitated with straight cyanide, and filter-pressed.

I do not agree with Mr. Argall that the process is declining in Australia. It must be remembered that the only installations there are on the two mines mentioned, and each of these is a success. I know more about the Lake View Consols than about the Oroya-Brownhill, and can safely say that on the former property a most excellent extraction is obtained on $7 ore, and at quite a reasonable cost. The same applies to the Brownhill, but I have not the same personal knowledge of this mine as I have of the other.

F. PERCY ROLFE.

Keystone, Wyoming, December 17.

College Instructors.

The Editor:

Sir—A recent utterance of yours made at the dedication of the Hearst Memorial Mining Building at the University of California has opened a subject of vital importance. I refer particularly to your well-timed suggestion that instructors in the mining colleges should divide their time equally between teaching and practical work, each year of the one followed by a year of the other. I greatly desire to see more interest displayed in this question.

To one who understands the situation, and particularly to one who has viewed the matter from various points of view, the need of this arrangement appears so obvious that little remains to be said. Yet neither the great public, that court of last resort, nor the majority of our leading educators, appears to be thinking at all about it. An overgrown conservatism at times clogs the wheels of real progress. The greatest weaknesses in university training today are directly due to the lack of some such procedure as you have mentioned.

There are two definite and distinct reasons why instructors in technical schools need more actual contact with the everyday hard-working world. One of these is of strictly practical nature; the other possesses a moral aspect. And the former is not a whit more important than the latter.

Firstly, each instructor in engineering needs to study the application of scientific principles under the conditions obtaining in actual practice, that his class-room work may be in touch and infused with the real life of the profession. We have all had experience with the 'theoretical' man, the man who is always in trouble over the failure of his theories. Paradoxical as it may seem, the 'theoretical' man does not fail because of a superabundance of theory, but because of a lack of theory. In other words, he fails to grasp all the conditions under which he is laboring and therefore applies too few principles. And the typical college professor is the type of theoretical man. Why? Merely because he does not appreciate all the numerous details of actual practice. I have seen such a man, eminent in his own specialty, visit a reduction plant using the very methods upon which he is an authority, and make foolish statements and suggestions that would disgrace a hod-carrier. Yet he is not to be blamed. He is the result of an unintelligent educational system. Surely it is obvious that were men of this character to spend alternate years in actual work in the field, the grade of their college work would be raised far above its present level. What can we expect of our college graduates if they are always dependent for their instruction upon men who never comprehend actual living conditions in the larger world of labor? The students themselves feel this, with the result that much of their college work is skimmed over and a vast amount of training valuable in itself is cast aside as of little worth. On the other hand, if students feel that they are under men who do understand that which is outside the college doors, the quality of their work is vastly improved. In my senior year at college, while on a trip through the mines, I was greatly impressed, though not favorably, by the remarks of a young mining engineer who had graduated some years previously. His statement, almost verbatim, was this: "A college education is a nice thing to have and we are all glad we have had one, but when you get through, just take your education, fold it up, put it in your back pocket and forget it." This man was a superior student and a capable hard-working fellow who was apparently leaving no stone unturned in his attempts to achieve success. He stands as the commonest type of mining graduate one meets today. There is no need here for a discussion; these things are themselves all too eloquent of a lack of correlation between our colleges and everyday life. A university is truly a little world in itself, yet there must not be such lack of contact between it and the larger activities outside that each year's graduates are at first like children wandering in an unknown land, who long wonder of what good to them was their Alma Mater.

Secondly, instructors in technical schools need to keep in living touch with the work of their profession in the world, that they may realize fully what is needed there, and that their class-room work may have that inspiration which comes only from a real knowledge of human affairs. Of all the criticisms of higher education, I think the greatest is that the college graduates know so little of the real needs of humanity. The reason is not hard to find. The usual professor or instructor is all too ignorant of the deep throbbing life beyond college gates, with

its constant striving for higher things, both of matter and of the spirit. Our college graduates not only often lack adequate knowledge of the application of the principles underlying their profession, but fail in that essential test of the truly educated man, namely, good citizenship. Now of all times do we require educated men, men who can and will actively aid in building up a higher standard of social intercourse. This can be only when our university faculties are in touch and sympathy with the great current of human events. This applies to all departments of education, but particularly to the technical schools, for our young engineers possess vast potentialities for good in the world today. The race is advancing mentally, morally, and spiritually through its ever-strengthening grasp upon natural phemonena and laws, so that the men who deal professionally with these can do much to upbuild our social structure.

The whole matter can be summed up upon either a narrow or a broad plane. It may be said that if we desire our college-bred engineers to obtain during their undergraduate years the fullest possible knowledge of their profession, we must have men to teach them who know both theory and practice, who can elucidate all necessary principles and explain fully their application to the world's work. Such teachers can be had only by adopting some such method of procedure as you have suggested. Further, if one is not satisfied with the above narrow statement, as I am not, it can be put as follows: If our colleges and technical schools are to produce men characterized alike by thoroughness of training in their particular professions and a broad sympathetic insight into the social movements of the times, we must first have teachers who are true leaders in thought and action. To know books one must spend many quiet hours with them; to know the world one must be of it as well as in it.

The country is ever calling for *men*, and there be many who condemn our great public institutions of learning because they fail to produce many *men*. The country must learn that for *men* to be produced other *men* must be working to produce them. We must have instructors who know the world from actual contact and association with it. If more money is needed in order to get such a condition, let us have it; if more men are needed, let us find them. But in any case let us have our instructors with their fingers upon the pulse of struggling humankind.

JOHN A. REID.

Stockton, Cal., November 27.

Cornish Pumps of New Design.

The Editor:

Sir—In your issue of December 14 mention is made of Cornish pumps being used at the Berry United mine near Ballarat, in Victoria.

It may interest you to know that two double sets of these pumps were also installed in the Keystone shaft of the Loddon Valley Gold Fields Ltd., at Moorlort, in the same State, to pump, in two stages, from what was called the 500-ft. level of the mine.

The accompanying photograph clearly shows the construction of these pumps, and some departure from the usual form will be noticed. The flanges are the only flat surfaces in the design; and the old, square box-section clack chamber, which may have an excuse for its existence in smaller sizes, is discarded as being altogether unsuitable for a pump with 26-in. diam. plunger. The H construction is modified to bring separate parts of the pump into convenient weights and sizes for handling. The joints are all made with ½-in. diam. rubber insertion packing compressed into suitable recesses arranged in meeting faces. The valves are clearly shown, and are practically identical with the valves used by Henry Teague in 1863. The main valve ring is made of cast steel, the top valve of cast iron, the seat being of the common 'clack' design.

The Y on the top of the discharge-valve chamber is fitted with a snifter 6-in. diam. and the branch is to carry an air-chamber. This is charged by means of an apparatus of simplest automatic operation, and the desired water-level in each chamber, determined by observation, is maintained by means of a small escape pipe connected between the air-chamber and the discharge-pipe line. When the air-chambers were to be installed one of the 'old timers' was surprised and disgusted at the willful waste of money. "And what's the good of air-chambers anyhow? They're no good. Why? I never saw one on a Cornish pump in all my life!"

These pumps were built by the Austral-Otis Engineering Co. of Melbourne, from designs by the writer, at that time mechanical engineer for Bewick, Moreing & Co. in Victoria. The plungers are 26-in. diam. with stroke of 10 ft. and at a speed of 8 rev. per min. of crank-shaft; the plunger displacement is 3,175,000 gal. per 24 hr.; or assuming a slip of 10%, which is probably excessive, the net delivery would be 2,857,000 gal. per 24 hours.

A Cornish pump plant of large capacity should give a total combined efficiency of about 80%; this being taken from the throttle valve of the engine to the water-delivery. Cornish pumps of much less capacity cannot be expected to afford equal efficiencies. An electrically driven turbine pump-plant, comprising steam generating apparatus, can hardly be expected to give a total combined efficiency of more than about 45%. The application of electrically driven pumps has had some encouragement during the past few years and some of them may be showing satisfactory results. Such plants are usually more attractive than the cumbersome and expensive Cornish pump. The saving of expense by installation of the cheaper plant may be fully warranted when the life service of the plant falls within the time limit set by the angular contact of the two lines on a diagram of costs representing the combined first costs, running expenses, interest, etc., appropriate to the respective efficiencies.

E. P. JONES.

San Francisco, January 4.

A Difficult Bit of Geology.

The Editor:

Sir—A few years ago, while in Mexico, my attention was called to what was represented as being a very large body of low-grade gold ore, sufficiently rich to be made profitable, if equipped with such a plant as the amount of ore seemed to justify.

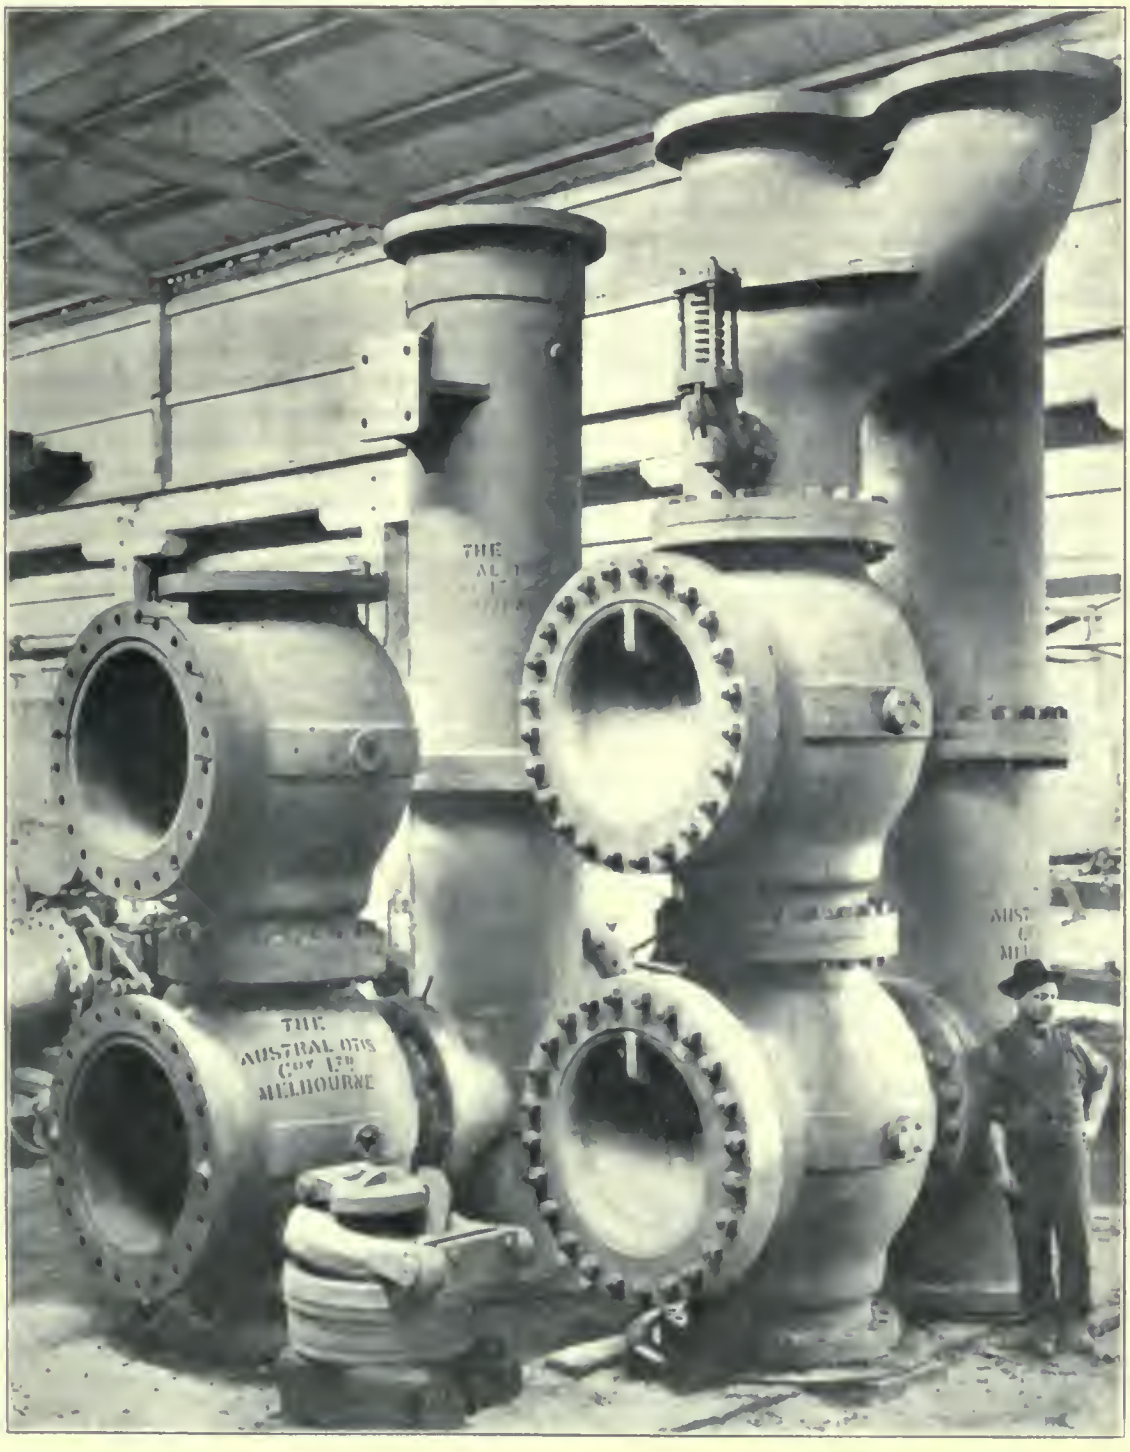
My informant was a well educated man, a graduate of Yale, a man who had traveled extensively, of some experience in mining matters, who had assisted in an examination and sampling of the mine in question, and I could believe had no object in trying to mislead me. A few weeks later, while in Culiacan, Sinaloa, I met a man from the immediate vicinity of this property, who, in answer to my inquiry, spoke well of it as a matter of casual observation, and at my request said that upon his return home he would again look at it and let me know whether or not it would justify a more careful examination. This man was an American of ordinary intelligence and education, of much experience as a miner and prospector, and, what is more, an honest man.

In a few days he wired me to come and see the mine,

which I did at once. I found the mine being worked by Mexicans, and that during the preceding month, as representing one month's work, they had cleaned up about $1800 in gold from one *arrastre*, run by the motive power of one burro; which was certainly an encouraging showing, so I entered upon an examination more than usually hopeful of a favorable result.

For a time the mine was quite a puzzle, which my preliminary work did not unravel, and I entered upon the work of sampling uncertain what was the form and nature of the mineralization. But in the study of such cross-sections as would best represent the value of the orebody, or bodies, as a mining proposition, and watching the work of the miners, it became less of a puzzle, until after some hours its true character became a certainty, and I said to my companion that I did not care to take more samples; that the property was all right for Mexicans to work in the way in which it was now being worked; but that as a mining proposition, for commercial profit on any considerable development and investment, it was valueless.

A description and explanation of the geology of the mine will perhaps make plain my reasons for this conclusion, and be instructive to some one who might have a similar puzzle to work out. The mine, or ore deposit, occurs at the valley terminal of a mountain spur which



Pumps for the Berry United Mine, Victoria.

in its uplift has intruded a fissure, which it probably caused, in a not very heavy andesite flow that covered the country, and which, while being a plastic porphyritic rock, was sufficiently rigid to not flow but lift the andesite as a blanket on its sides without shattering it except at the valley terminal, where it gave it a thrust. This shattering created gashes or fissures, which permitted of a rapid cooling of the hot plastic underlying porphyry, and consequently a gashing coinciding in a measure with the overlying andesite gashing. The unbroken edge of the

andesite lying as a blanket on the sides of the mountain-spur formed a trough, in which the drainage from the central porphyry apex percolated down to the valley terminal, gathering the minute quantities of gold from the disintegrating rocks and precipitating them in these comparatively colder, because more exposed, gashes above described.

These numerous gashes on, or around the end of the mountain-spur, all mineralized, gave the deceptive appearance of a mountain of ore, and might easily mislead. Indeed, I subsequently learned that some 15 years prior to my examination a Chicago company had spent something like $100,000 in building and putting in operation a mill, only to shut down after two weeks' run for the want of ore of sufficient value to pay; all the ground between the gashes proving valueless. Had they spent $5000 in proving the mine before building a mill they would have saved themselves $95,000. A gash vein is not unusual and is generally easily recognized; but a system of such veins so closely related is unusual, and might deceive an inexperienced man.

JOHN M. HENTON.

Rhyolite, Nev., December 17.

A Suggestion.

The Editor:

Sir—Without disparaging the excellent work done by the corps of geologists maintained in the field by the U. S. Geological Survey, there is undoubtedly much justice in your criticism that geological reports partake largely of the nature of obituaries. The methods of the Survey do not seem to favor real pioneer work. There is more or less work about affording guidance to the prospector, but as it works out in the field it is rather the prospector who guides the geologist.

Now, would it not be economy all around, instead of paying the professional geologist for collecting data largely furnished gratis by mining men and prospectors, to pay the properly equipped prospector himself under certain conditions for reporting on territory which he explores. A fraction of the liberal salaries which permit young geologists to acquire experience in the Government service would grubstake a goodly number of first-class prospectors and probably lead to the discovery of new mineral districts. Probably many young members of the Survey would prefer a grubstake and the chance of doing something on their own account to an assured salary. It appears some such plan might be worked out that would stimulate prospecting, make better geologists, and develop a spirit of independence where it seems to be greatly needed—among our educated men.

MUSHER.

Ketchikan, Alaska, December 17.

Cobalt.

The Editor:

Sir—In your issue of December 28, there is an article written by myself on Cobalt. In this article I state: "Up to the beginning of the present year, about 12,000,000 oz. silver valued at about $7,500,000 have been sold." This is an error. I should have stated that the production to January 1907, was about 9,000,000 oz. valued at about $5,500,000. Kindly correct this.

The amount of ore sold for 1907 is nearly 15,000 tons, containing probably 10,000,000 oz. or more of silver. This does not take into consideration low-grade ore of, say, 60 oz. or less. Three concentrating plants are in operation on the Coniagas, McKinley-Darragh, and Cobalt Central. Two large public concentrating plants are being erected, one on the Nipissing, using dry concentration, and another called the Muggley concentrator. Various mining companies are contemplating installing concentrators. These, as well as the ore at present sold, should largely increase the production for the present year.

FRANK C. LORING.

Toronto, January 4.

BORAX IN CALIFORNIA.—San Bernardino, Inyo, and Ventura counties in California yield all the borax produced in the United States. The total output of crude borax for the year 1906 was 58,173 short tons, valued at $1,182,410. This was an increase over 1905 of 11,839 short tons in quantity and $163,256 in value. The most productive mine was that of the Pacific Coast Borax Co. near Marion, in San Bernardino county. The workings extend to a depth of about 600 ft. in veins of colemanite. However, about the close of 1906, the mine was abandoned and the entire force of 200 men was transferred to the Lila C mine in Inyo county. The Western Mineral Co., near Daggett, produced a small output by dissolving its material and evaporating to dryness in solar vats, yielding boric acid. The American Borax Co. at the same place mined a low-grade deposit and produced boric acid concentrate which was refined at New Brighton, Pa. In Inyo county, the Western Borax Co. is working 'marsh mud;' this is concentrated by boiling and the solution is then crystallized. Near Griffin, in Ventura county, colemanite is mined by the Frazier Borate Mining Co.; it is refined by the Stauffer Chemical Co., at San Francisco. The Lila C mine in the Death Valley region is expected to be the heaviest producer of borax in the State for several years. The deposit is a colemanite vein known to be about 2000 ft. long and from 6 to 18 ft. wide. It is a high-grade ore, that shipped in 1907 having a boric acid content of about 40%. The production is expected to be at the rate of 30,000 short tons annually. This will be shipped to the Pacific Coast Borax Co.'s refinery at Bayonne, New Jersey.

COPPER IN NEWFOUNDLAND.—The copper deposits of Newfoundland occur on the shores of Notre Dame bay, on the east side of the island. They are more properly designated as pyrite deposits; they derive their chief value from the fact that they are useful in acid-making. The Tilt Cove deposit, belonging to the Cape Copper Co., and the Pillys Island deposit are the only ones that are being worked. They are thick lenticular orebodies of cupriferous pyrite inclosed in tilted bands of slates with interstratified dolomites, serpentines, and diorites. Three orebodies are known as Tilt Cove. The old or East mine was opened on an orebody 200 by 300 by 120 ft., wedging at a depth of 120 ft. Another is from 22 to 35 ft. thick. The ore consists of pyrite with close-grained yellow chalcopyrite; it carries 4% copper and 1½ dwt. gold per ton. The Tilt Cove company mined 54,253 tons of ore in 1902. It carried 3.3% copper and yielded a net profit of $239,540. In April, 1905, the East mine yielded 1860 tons of ore averaging 3.25% copper and the South lode, 1977 tons, averaging 3.75% copper.

DAMAGE SUITS.—According to a decision just handed down by the Supreme Court of the United States suits cannot be brought in the United States Court, or in any State court of the United States, against the Mexican Central Railway Co., Ltd., for injuries received in Mexico, although the injured parties may be citizens of the United States. The decision disposes of 25 cases which have been pending on appeal. The decision is based upon the dissimilarity of the laws of Texas and Mexico, and the Supreme Court refuses to enforce the Texas law, although both the defendant company and the plaintiff come directly within the jurisdiction of the United States.

Copper Smelting in Tennessee.

Written for the MINING AND SCIENTIFIC PRESS
By J. PARKE CHANNING.

During the early part of 1907 the continued shortage of labor in the South prevented any material increase in the production of the tonnage treated from the mines of the Tennessee Copper Co., and the depression in the price of copper in the latter part of the year of course discouraged any increase at that time. Although the labor situation has materially improved, this condition of affairs still exists.

The production is in the neighborhood of 12,500,000 lb. per year, though the mines, railway, and smelter have been so equipped that, if conditions demanded, the production could readily be increased to 20,000,000 lb. per year. At the principal mine of the company, the Burra Burra, the 2½-ton skips have been replaced by 5-ton skips, and the steam-pressure on the hoisting engine raised proportionately, it previously having been reduced from boiler pressure before entering the cylinders. This idea was held in view in the original equipment of the property and has worked out with remarkable success.

For handling the men, cages similar to those used at the Quincy mine, on Lake Superior, have been introduced. The shortage of labor has prevented much development work during the year, but this has now been taken up again and the shafts at the various mines will be sunk during the coming winter. An order has been placed with the Bucyrus company for a special type of dipper-shovel operated by compressed air and this will be installed underground on one of the Burra Burra levels for the purpose of loading ore from the underhand stopes into the mine cars. It is hoped that this will produce a material saving in the cost of loading and will also solve to a very large extent the difficult problem of securing the common labor necessary for this very important part of mine operations.

On the railway, a large number of cars have been rebuilt and one new 100,000-lb. locomotive added to the motive power. At the smelter an immense improvement has been made in the metallurgical operations, due very largely to increased mechanical efficiency of the charging system and the slag disposal system. Heavier locomotives and larger and stronger cars have been introduced. Heavier rails have been installed, so that delays from derailments have been practically overcome. It has also been found that the tuyere area of the furnaces was too small to permit of proper punching of the crust inside the blast-furnace. However, by paying particular attention to this point and keeping the tuyeres well open, the volume of blast has been materially increased, with a consequent better running of the furnaces; in fact, four furnaces at the end of the year are handling as much ore as six furnaces at the beginning of the year. It is intended to enlarge the tuyere openings by making out of each pair of tuyeres a long slotted tuyere, and it is hoped that the tonnage of the furnace will be still more increased. The larger volume of air, curiously enough, has resulted in an increased amount of FeO in the slag and a consequent reduction in the amount of silica necessary or else by an increase in the grade of the matte. During the early part of the year the first matte went about 10% copper. At present it seldom runs below 19%, and at times with a new furnace and the tuyeres well open, a 30% matte has been made continuously for 18 hours. There is a possibility that in time the second or concentrating operation may be entirely eliminated, though it is still too early to predict such a radical change. Now that the problem of making sulphuric acid is of as great importance as the production of matte, it is necessary to consider the volume of air blown into the furnace. Still, indications point to the probability that all air within reasonable amounts blown into the furnace combines with either the carbon of the coke or the sulphur and iron of the ore.

In the converting department the only change has been in the final determination to abandon the re-smelting of converter-slag and the pouring of that portion which is fluid into the settlers. This has been a much mooted question, but at Tennessee it has been definitely proven that unquestionably the commercial gains are far in excess of any possible metallurgical loss. The converter-floor is kept remarkably clean by pouring the last dregs of melted material from the converter ladles into small hand-pots, which are then run out and dumped. The skull in the ladle is dumped on the floor, breaks into pieces, and is not cemented together by the usual small amount of slag left in the ladle under old conditions.

The sulphuric acid plant has just been completed and at the present time the gases are going through it, and such minor adjustments are being made as are necessary in any plant of this size. Sufficient progress has, however, been made to show that without doubt the process will be a success. It is found that the proper grade of gas may be obtained by an adjustment of the various dampers. It is still too early to go into the details of the process, but it is hoped that later on a careful technical description of the results achieved will be given out.

CERRO DE PASCO.—It was five years ago July 9, 1907, that American engineers were sent to Peru to examine the Cerro de Pasco mines for the Hearst Estate and J. B. Haggin, as a result of which these two interests purchased the property. During these 5½ years a total of $17,500,000 has been expended in the purchase and development of this property to the producing stage, as follows: For the mines, $7,000,000; smelter, $3,000,000; railroad, 120 miles, $2,500,000; development, $5,000,000; total, $17,500,000. R. H. Channing, formerly general manager for the Utah Consolidated Co., is now in charge of the Cerro de Pasco. Three or four furnaces of 250 tons capacity each are now in commission and 2,000,000 lb. blister copper per month is being shipped into the United States for refining. Most of this product is being refined by the American Smelting & Refining Co. at its Keyser plant in Baltimore and the product has subsequently found a market in Europe. Operating conditions at the Cerro de Pasco make the production of copper a matter of considerable difficulty, as the mines are 14,000 ft. above sea-level and the native labor is very incompetent; 6000 men are employed. There is a vast amount of ore in sight in the mines which averages about 10% copper in the Cerro de Pasco mines and 15% copper in the Morococha mines, also owned by this company. There are 75,000 tons of ore on the Cerro de Pasco dumps and 40,000 tons on the Morococha dumps which will average 15% copper. The ores are found within a district one mile wide and two miles in length and they carry sufficient gold and silver values to permit of cheap costs, notwithstanding the many disadvantages of operation. While probably the Cerro de Pasco has proved one of the most expensive copper propositions ever developed, the leading interests in the company express no fear that eventually they will get back their initial expenditure of $17,500,000. J. B. Haggin, one of the largest owners, is 87 years of age. He has been in mining enterprises all his life and is the guiding genius in this Peruvian enterprise.—*Boston News Bureau.*

California Minerals.

Written for the MINING AND SCIENTIFIC PRESS
By ARTHUR S. EAKLE.

More than three hundred definite mineral species are known to occur in California, and of these about ten per cent were discovered first in the State and described as new minerals. A brief description of these distinctively Californian minerals, with the date of discovery, may be of interest.

ARAGOTITE. A hydrocarbon compound found as bright yellow scales in the silicious dolomite of the New Almaden cinnabar mine. Discovered in 1872 and named for the astronomer, Arago. The mineral was subsequently found with cinnabar at the old Redington mine, at Knoxville, in Lake county.

BAKERITE. A hydrous boro-silicate of lime, $(Ca_8B_{16}Si_6O_{35} + 6H_2O)$. Found in white amorphous masses associated with colemanite and ulexite at the borax deposits near Daggett, in San Bernardino county. Discovered in 1903 and named for R. C. Baker, of Nutfield, Surrey, England.

BENITOITE. A titano-silicate of barium, $BaTiSi_3O_9$. Found in hexagonal crystals of a beautiful blue color, transparent and hard, near the headwaters of the San Benito river in San Benito county. Discovered in 1907 and named for the county. This is the latest find of a new mineral in the State, and it is important as a gem stone.

BOOTHITE. A hydrous copper sulphate, $CuSO_4 + 7H_2O$. Found in green crystals and powder intimately associated with chalcanthite in the Alma pyrite mine, at Leona Heights, in Alameda county. Discovered in 1903 and named for Edward Booth, of the University of California. It has been found since at Campo Seco.

CALAVERITE. A telluride of gold and silver (Au, Ag)Te_2. Found as pale bronze yellow masses in the old Stanislaus mine, Calaveras county, associated with other tellurium minerals. Discovered in 1868 and named for the county. It has been found in abundance later at Cripple Creek, Colorado.

COLEMANITE. A hydrous borate of lime, $Ca_2B_6O_{11} + 5H_2O$. Found as colorless and whitish monoclinic crystals in Death Valley, Inyo county. Discovered in 1882 and named for W. T. Coleman, of San Francisco. Found in greater abundance and beautiful crystals during the following year in the Calico district, San Bernardino county. Colemanite is an important mineral for the manufacture of borax.

CROSSITE. A silicate of alumina, iron, lime, magnesia, and soda, forming a soda-amphibole. Found in lath-shaped crystals of a dark blue color as a constituent of some crystalline schists north of Berkeley, in Contra Costa county. Discovered in 1894 and named for Whitman T. Cross, of the United States Geological Survey.

HANKSITE. A sulphato-carbonate of soda, $4Na_2SO_4$, Na_2CO_3. Found in good hexagonal crystals associated with borax at Borax lake, San Bernardino county. Discovered in 1885 and named for Henry G. Hanks, former State Mineralogist.

IDDINGSITE. A hydrous silicate of iron, lime, magnesia, and soda. Found as bronze and brownish-red crystals in some of the eruptive rocks at Carmel Bay, Monterey county. Discovered in 1893 and named for J. P. Iddings, of Chicago University. Observed subsequently as a constituent of rocks from other localities.

IONITE. A hydrocarbon found as a compact earthy brownish-yellow substance in the lignite of Ione valley, Amador county. Discovered in 1878 and named for the locality.

KNOXVILLITE. A hydrous basic sulphate of chromium, iron, and alumina. Found as greenish-yellow plates associated with redingtonite in the old Redington cinnabar mine, at Knoxville, Lake county. Discovered in 1888 and named for the locality.

LAWSONITE. A hydrous silicate of lime and alumina, $H_4CaAl_2Si_2O_{10}$. Found in good orthorhombic crystals and plates of a light bluish-gray color in the crystalline schists of the Tiburon peninsula, in Marin county. Discovered in 1895 and named for A. C. Lawson, of the University of California. Lawsonite has been observed subsequently as a constituent of glaucophane schists and gneisses in many other localities.

MARIPOSITE. A hydrous silicate of alumina, magnesia, potash, and chromium, forming one of the micas. Found as apple-green scales and flakes in the rocks of the Mariposa region. Long known as constituent of the crystalline schists of the Mother Lode region, but first described in 1867 and named for the Mariposa Estate.

MELONITE. A telluride of nickel, perhaps Ni_2Te_3. Found in reddish white granular and foliated particles in the Melones mine, Calaveras county. Discovered in 1867 and named for the mine. Probably exists also at Boulder, in Colorado.

METACINNABARITE. Black sulphide of mercury, HgS. Found in amorphous masses at the Redington cinnabar mine, at Knoxville, Lake county. Discovered in 1872 and named for its difference from cinnabar. Later found in good crystals at the original locality and at New Almaden, New Idria, and elsewhere.

NAPALITE. A hydrocarbon, C_3H_4. Found as a waxy bituminous substance of a dark reddish-brown color, associated with cinnabar at the Phœnix mine, in Napa county. Discovered in 1888 and named for the county.

NORTHUPITE. A double carbonate of soda and magnesia with sodium chloride $MgCO_3, Na_2CO_3, NaCl$. Found in small colorless to brownish octahedral crystals in the clay from a boring at Borax lake, San Bernardino county. Discovered in 1895 and named for C. H. Northup.

PARTZITE. A hydrous oxide of antimony mixed with other metallic oxides. Found in blackish-green to black masses in the Blind Springs district, Mono county. Discovered in 1865 and named for A. F. W. Partz. Partzite is not a well-defined mineral species.

PIRSSONITE. A hydrous double carbonate of lime and soda, $CaCO_3, Na_2CO_3, 2H_2O$. Found in good orthorhombic crystals, colorless and white, associated with northupite at Borax lake, in San Bernardino county. Discovered in 1896 and named for L. V. Pirsson of Yale University.

POSEPNYTE. A hydrocarbon, $C_{22}H_{36}O_4$. Found in plates and nodules of a dirty light green color, associated with cinnabar in the Great Western mine, Lake county. Discovered in 1877 and named for the geologist, F. Posepny.

REDINGTONITE. A hydrous sulphate of chrome, iron, and alumina. Found in finely fibrous and crystalline masses of a pale purple color, associated with knoxvillite at the Redington cinnabar mine, in Lake county. Discovered in 1888 and named for the mine.

ROSCOELITE. A silicate of vanadium, aluminum, and potassium, forming a vanadium mica. Found in micaceous masses and scales of a dark clove-brown to brownish-green color, intimately associated with gold, at Granite creek, near Coloma, in El Dorado county. Discovered in 1874 and named for Sir Henry E. Roscoe, of Manchester, England. The mineral was first called colomite. It was observed later near Sutter's mill and in the Magnolia district, Colorado.

SONOMAITE. A hydrous sulphate of magnesia and alumina $3MgSO_4Al_2(SO_4)_3 + 33H_2O$. Found as silky

colorless crystals near the geysers, Sonoma county. Discovered in 1876 and named for the county.

STIBIOFERRITE. An impure hydrous oxide of antimony and iron. Found as a brownish-yellow coating on stibnite in Santa Clara county. Discovered in 1873 and named stibioferrite from its composition. It is probably not a distinct species.

SULPHOHALITE. A sulphato-chloride of soda, $3Na_2SO_4$, $2NaCl$. Found as transparent isometric crystals of a greenish-yellow color, implanted on hanksite from Borax lake, San Bernardino county. Discovered in 1891 and named from its composition.

TYCHITE. A double carbonate of magnesia and soda with sulphate of soda, $2MgCO_3 2Na_2, CO_3, Na_2SO_4$. Found as small octahedral crystals among many northupite crystals from Borax lake, San Bernadino county. Discovered in 1905, and named from the Greek word for 'luck.'

Names have also been given to varieties of well-known species and to minerals which were supposed to be new. Thus:

BERNARDINITE. Supposed to be a new fossil resin from San Bernardino county, but proved later to be a fungous growth impregnated with resin. Discovered in 1879 and named for the county.

CALIFORNITE. A variety of vesuvianite found in very compact green masses, resembling jade; on the south fork of Indian creek, about 90 miles from Yreka, Siskiyou county. Discovered in 1903 and named from the State.

KUNZITE. A variety of spodumene, a lithia-alumina silicate. Found in transparent crystals and cleavage pieces of amathystine purple and magenta colors, in the tourmaline district of Pala, San Diego county. Discovered in 1903 and named for George F. Kunz of New York. The mineral is important as a beautiful gem stone.

PALACHEITE. Supposed to be a new hydrous sulphate of iron and magnesia, but proved later to be botryogen. Found in masses of loosely coherent crystals of a brick-red color in the Redington cinnabar mine, at Knoxville, Lake county. Discovered in 1903 and named for Charles Palache, of Harvard University.

TRAUTWINITE. Supposed to be a new silicate of chromium, iron, and calcium, but proved later to be an impure chrome garnet, uvarovite. Found as green coating on chromite in Monterey county. Discovered in 1873 and named for J. C. Trautwine.

A CHECK-OFF SYSTEM whereby it is possible at any time to determine the exact number of miners and other laborers underground is in use at some large mines. At the office there is a carefully designed check-board, large enough to be properly spaced with nails at equal distances, so that numbered checks can hang in order, and the check-clerk can quickly pick off any number from the board. Each employee receives a check when he reports for work and returns it to the office when the day's work is done. One advantage of a careful system of this sort is that no man can be injured by falls of roof or local explosions and be left in the mine without his absence being noted. This leads to a prompt investigation as to the cause of non-appearance of the miner and the sending to him of assistance. A notable feature in connection with some recent explosions in coal mines has been the inability of the officials to determine the number of men underground at the time of the explosion; the check-off system would have prevented this uncertainty. In coal mining, after the day's work has started the superintendent can closely figure how many tons of coal the mine will probably produce for the day, by looking over the board and noting the number of men underground.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

J. W. S. sends Quartzite.

Dolomitic Limestone was sent by C. D. B., of Yreka California.

D. C. F., of Tonopah, Nev., sends Tripolite or Diatomaceous earth.

Specimens sent by H. C. A., of Wallace, Idaho, have not been received.

W. B. H., of San Francisco, sends specimens No. 1, 2, and 3 of Soda Rhyolite.

A specimen of specular Hematite in Epidote and Quartz was sent by A. H. F., of Argenta, Montana.

Black sand, consisting of Magnetite, Ilmenite, red Garnet, and Quartz grains was sent by J. P., of Eureka, Nevada.

Specimens sent by C. H. L., of Silver City, New Mexico, are: No. 1, Obsidian or Pitchstone; No. 2, Clay stained by Hematite.

The two specimens from R. R., of Hawthorne, Nev., are: No. 1, granitic rock stained by Chrysocolla; No. 2, veins of Chrysocolla and Malachite.

M. L. M., of San Juan, Porto Rico, sends: No. 2, Chalcocite, Bornite, Malachite, and Azurite in an olivine basalt; No. 3, Basalt; No. 4, altered basaltic rock.

The rocks received from J. R., of Coffee, Cal., are: No. 1, Talc-Schist; No. 2, green and brown Chlorite; No. 3, Serpentine; No. 4, Hornblende-Biotite-Andesite.

Specimens from Wonder, Nev., marked H. G. G., are: No. 29 and 30, probably mineralized Rhyolite or Andesite; No. 31, Andesite; No. 32, Biotite in Rhyolite; No. 33, Diorite.

Minerals from Beatty, Nev., marked A. J., are: No. 1, Chalcocite and Malachite; No. 2, Bornite, Chalcocite, and Malachite; No. 3 and 4, Chalcopyrite in granitic rock; No. 5, Chalcopyrite and Limonite; No. 6, Pyrite; No. 7, Schist.

C. H. B., of Jalisco, Mexico, sends: No. 1, Meta-Andesite; No. 2, Hornblende-Syenite; No. 3, Obsidian; No. 4, Andesite; No. 5, 6, 7, and 8, Metamorphics, mostly Quartzite; No. 9 and 10, Andesite; No. 11 and 12, Rhyolite; No. 13, Quartzite; No. 14, Meta-Andesite; No. 15, Rhyolite; No. 16 and 17, Andesite.

The rocks from Iron Mountain, Mich., marked J. H. H., are: No. 1, Mica-Schist; No. 2, Pyrite in Mica-Schist; No. 3, Slate; No. 4, Slate or Quartzite; No. 5, Chlorite-Schist; No. 6, Mica-Chlorite Schist; No. 7, Pyrite in Amphibolite; No. 8, Quartzite; No. 9, Quartzite; No. 10, Schist; No. 11, Talcose-Schist; No. 12, Chalcopyrite in Quartz; No. 13; Quartzite; No. 14, Chert; No. 15, Quartzite; No. 16, Amphibolite.

The samples from Joseph, Idaho, marked A, are: No. 1, specular Hematite; No. 2, Chalcopyrite; No. 3, Hornblende; No. 4, Tetrahedrite and Pyrite; No. 5, Calcite; No. 6, Magnetite in Diorite; No. 7, Basalt; No. 8, Gneiss; No. 9, Quartzite; No. 10, Magnetite; No. 11, Pyrite and Hematite; No. 12, Diorite; No. 13, Hematite; No. 14, Aplite; No. 15, Biotite-Gneiss; No. 16, Epidote; No. 17, Gneiss; No. 18, Diorite; No. 19, Magnetite; No. 20, Magnetite in rock; No. 21, Granite; No. 22, Diorite.

Copper Production.

From present indications the output of copper in the Territory of Arizona last year amounted to 260,250,000 lb. and that Territory took the first place in copper output in the United States. This is not due to any increase in its production, however, but is the result of the falling off of 120,000,000 lb. in the production at Butte.

We estimate the production of copper on the American continent in 1907, compared with 1906, as follows (in pounds):

	1907.	1906.
Arizona	260,250,000	284,000,000
Montana	240,000,000	350,000,000
Michigan	230,000,000	228,000,000
Utah	98,750,000	60,000,000
California	21,000,000	15,000,000
Other States	15,000,000	35,000,000
Mexico and Canada	150,000,000	200,000,000
Total production	1,015,000,000	1,172,000,000

We figure the production in Arizona in 1907, by camps and companies, as follows:

Camp.	Mine.	Production 1907.	Production 1906.
Bisbee	Copper Queen	88,000,000	96,481,904
	California & Arizona	39,550,000	47,164,000
Clifton-Morenci	Arizona Copper Co.	27,000,000	25,960,000
	Shannon Co.	14,200,000	11,964,000
	Detroit Co.	15,000,000	16,906,000
Globe	Old Dominion	36,000,000	34,400,000
Jerome	United Verde	33,000,000	38,000,000
Miscellaneous		7,500,000	10,000,000
Total		260,260,000	280,875,904

The above totals in each year include a certain amount of Nacozari and Greene Consolidated production treated by the Copper Queen and Old Dominion in the form of concentrates and used for fluxing purposes. Had it not been for the unsettled copper situation, which necessitated restriction of the 1907 output of copper in the Territory, Arizona would undoubtedly have reached the 300,000,000-lb. mark, whereas production fell off 20,000,000. There is now a smelting capacity in the Territory sufficient to output considerably in excess of 300,000,000 lb. per annum.

Utah has made a notable gain in copper production in 1907 by reason of developments in the Utah Copper Co., Boston Consolidated, and Cactus properties and the operation of the new Garfield smelter. That smelter is now equipped to output 6,000,000 lb. copper per month, largely by reason of the treatment of Utah copper and Boston Consolidated concentrate. This would indicate an output from this smelter alone of 72,000,000 lb. per annum. The other smelters in the State are now shut down or preparing to shut down, and this fact may have some bearing upon Utah copper production in the new year, although, with any improvement in copper prices, the Utah ores would probably be shipped outside of the State.

Increased copper production is to be expected from California during 1908 with the enlarged capacity of the Mammoth smelter, the new Balaklala smelter, 90% completed, the Mountain Copper Co. plant reconstructed, and the new Bully Hill smelter about ready to blow in. A production of about 50,000,000 lb. copper from California in 1908 is within reason. Nevada will also be a factor shortly, for the Ely camp will be productive by April. A production of 50,000,000 lb. from the State next year, however, is about the limit of expectations.—*Boston News Bureau.*

IN structural materials the total annual production of the State of California is now between seven and eight million dollars. There are included brick and pottery clays, portland cement, lime and limestone, asphaltum, macadam, rubble and concrete rocks, paving blocks, marble, granite, sandstone, serpentine, slate, glass, sand, and soapstone.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

Where blasting was required to be done after the general work in the mine ceased, and where it was the custom, when one miner left his work before quitting time, for his asssistant to fire off his blast, it was held that such an assistant in firing the blast of his fellow miner was not a volunteer, and that in case of injury he was entitled to recover.

McHenry Coal Co. *v.* Render, (Ky.) 104 Southwest, 996, Nov., '07.

Proof that a mine was not properly ventilated, that the air was bad, and that an explosion of gas occurred, was held sufficient proof of negligence on the part of the mine operator.

McHenry Coal Co. *v.* Render, (Ky.) 104 South, 996, Nov., '07.

Where it appeared that a miner, by reason of an explosion of gas was thrown some distance down the entry and bruised and was severely burned, a verdict of $6,000 was held not excessive and such verdict could not be set aside on appeal because the evidence of the defendant indicated that there was no explosion of gas, but that the plaintiff was burned by a blast which he exploded.

McHenry Coal Co. *v.* Render, (Ky.) 104 Southwest, 996, Nov., '07.

The failure of the locator to discover oil and a failure to retain possession and prosecute the work, was held fatal to the validity of the location under the statute providing that the entry of petroleum lands should be governed by the law relating to placer claims.

New England Oil Co. *v.* Congdon, (Cal.) 92 Pac. 180, Oct., '07.

The mere posting of notice and marking boundaries on the ground will not exclude others from a peaceable entry where the first locator had made no discovery, and had not retained possession and prosecuted the work looking to a discovery.

New England Oil Co. *v.* Congdon, (Cal.) 92 Pac. 180, Oct., '07.

Where an oil claim was located and the boundaries marked, but no discovery was made, and a cabin was constructed without furniture, doors or windows, and no one lived in it, and a watchman was employed to watch the claim in connection with other lands, but no drilling or actually developed work was done nor any steps taken in that direction, the land was held subject to re-location.

New England Oil Co. *v.* Congdon, (Cal.) 92 Pac. 180, Oct., '07.

Where there was a mining district recorder whose place of business was publicly known, it was held essential to a valid record of a mining claim that the certificate of location be recorded with the district recorder, as well as with the county recorder.

Ford *v.* Campbell, (Nev.) 92 Pac. 206, Nov., '07.

A certificate of location of a mining claim describing it as situated about two miles from a certain town, was held not to constitute a substantial compliance with the statute requiring a description of the location of the claim with reference to some natural object or permanent monument.

Ford *v.* Campbell, (Nev.) 92 Pac. 206, Nov., '07.

The recording of the certificate of location of a mining claim is not an essential requisite to a valid location.

Ford *v.* Campbell, (Nev.) 92 Pac. 206, Nov., '07.

There is no presumption that subterranean rights under lode mining locations were considered and determined in an adverse suit in the absence of the record of such suit.

Lawson *v.* United States Co., 28 Superior Court Reporter 15, Oct., '07

The Copper River District, Alaska—II.

Written for the MINING AND SCIENTIFIC PRESS
By W. M. BREWER.

In my previous communication on this subject I discussed the transportation problem. In this I shall discuss briefly the geology and occurrences of mineral.

The Copper river itself flows in a southeasterly direction, and its chief tributary, the Chitina, flows soutwesterly, the confluence being some distance above the Abercrombie rapids. Both of these rivers are navigable for light-draught stern-wheel steamers, and during the summer of 1907 a steamer made the trip up the Copper river from Abercrombie rapids as far as Copper Centre, which is a telegraph station on the Valdez-Fairbanks trail about 120 miles from Valdez. The same steamer also made a trip up the Chitina from its mouth to the mouth of the Nizina, a few miles northeasterly from and above the mouth of the Lakina.

Up to the present time the only discoveries of copper ore made on the Copper river proper are located near Taral at a point above the Abercrombie rapids and on the route of the projected line of railroad under construction from Cordova. T. W. Blakney located several claims on which copper ore outcrops some three years ago, and has since been doing the necessary representation work with a view to having some of the claims opened up sufficiently to be able to ship ore whenever the railroad is completed to Taral. No other discoveries have been reported between this point and the Kotsina river, a branch of the Chitina, several miles distant from Taral to the northeast. The first locations made in this region are on Elliott creek, a branch of the Kotsina and apparently the western limit of the mineralized country known today as the Copper River copper country.

These occurrences of copper ore were fully described by W. C. Mendenhall and F. C. Schrader of the United States Geological Survey in their report published in 1903. Since then the holdings of the Hubbard-Elliott company, comprising all of the known occurrences of copper ore on Elliott creek, have been examined by several mining engineers. These locations, from the best information I can obtain, are situated about 21 miles in an air line from the mouth of the Kotsina river, which would in all probability be the nearest point that the line of a trunk railroad would reach; consequently, the owners of the property will have to make arrangements for transportation between it and the mouth of the Kotsina river. However, shipments from the mine need not be delayed until the railroad is built to that point, because ore can be shipped from there by steamer to the Abercrombie rapids, to which point it is fully expected that the main line of railroad will be constructed during 1908. Therefore, whenever the mining property is developed to a shipping stage and some system of transportation installed from Elliott creek to the mouth of the Kotsina river, ore can be shipped to the smelters outside.

Apparently the mineralized zone extends northeast from Elliott creek across the Kotsina, Kushkilina, Chockosna, Lakina, and Nizina rivers, and possibly beyond into British territory. Until detailed geological examinations have been completed of both the United States and British territory, the full extent of mineralized country in this portion of Alaska and the Yukon cannot be determined. One thing is certain that when we consider the known discoveries of copper ore in what is known as the Copper River district, as well as in the neighborhood of the headwaters of the White, Alsek, and Tanana rivers, the superficial area is very considerable, greater possibly than the area of nearly any other copper-producing region.

Of course, at present this entire country is made up of isolated camps, as for instance, the Hubbard-Elliott camp on Elliott creek, the Gray camp on the Kotsina, the McCarthy camp near the headwaters of the Kushkilina, the Lynch and Greer camps near the headwaters of the Lakina, the Bonanza camp near the headwaters of the Nizina river. While a large number of prospectors have been attracted to this country ever since 1898, when the Hubbard-Elliott party went in, yet the number has not been sufficient more than to scratch the ground in the immediate vicinity of the most accessible portions, these naturally being adjacent to the streams; but gradually prospectors are extending their explorations into the territory between the rivers; indeed, during 1907 the country lying between the headwaters of the Lakina river and the Bonanza mine, a distance of several miles, was partially prospected, and several locations of copper ore were staked. In some respects this region is an easy one to prospect, because the rock formation is well exposed, the 'timber line' being low, in fact, you rarely find any timber growing above the river valleys, and that is scrubby. Glaciers of considerable extent occur at the headwaters of all the rivers and the rock formation shows evidence that these glaciers are of much less extent today than they have been in the past. In fact, it would appear as though the glaciers of Alaska and the Yukon are gradually becoming smaller.

The geology in the vicinity of the headwaters of the Lakina river is not as complicated as it is nearer the coast. Generally speaking, I found that the summits of the mountains were usually made up of crystalline limestone and that this was underlain by greenstone, in which occurred intrusive masses and dikes of amygdaloidal diabase. Of course, the limestone has suffered severely from erosion, so that frequently it is merely found overlying the igneous rocks in patches. Copper ore is found occurring at and near the contact between the limestone and the greenstone, as well as in the greenstone itself. The character of this ore is bornite with some chalcocite and chalcopyrite carrying from 4 to 42% copper, and where any quantity of solid chalcocite is found the copper contents will reach 70%. Other occurrences of ore are those found in the amygdaloidal diabase. This ore is native copper, much of it occurring as lumps weighing from a few ounces to several pounds, while the rock itself is found to contain small particles of native copper scattered through it to such an extent that samples are found to assay from 0.5 to 3.6% per ton.

Because of the limited amount of work that has been performed, it is not possible to estimate the commercial value of any of the occurrences of ore at the headwaters of the Lakina river. It is perfectly safe to say that on several mineral claims the prospects promise to develop into valuable mines, because the work done shows that the orebodies can be traced on the surface for some distance, say, for five or six hundred feet, the width varying from a few inches to 3 or 4 ft. These conditions apply to the occurrences of ore in which bornite, chalcocite, and chalcopyrite predominate. As far as the occurrences of native copper are concerned, the indications are that these may be found to possess great extent, and my reason for making this statement is that I observed intrusive blankets or sheets of amygdaloidal diabase exposed by nature on the hanging-wall side for a vertical height of 100 ft. or a horizontal measurement of about 600 ft. This was in a coulée formed in the mountain-side by erosion, where the greenstone hanging-wall had been carried away, leaving the sheet of amygdaloidal diabase exposed for a width varying from 15 to 15 ft., but the thickness of this sheet or blanket had not been determined at any point. The strike of this body is nearly east and

west magnetic, its dip being 30° southerly. The lines of strike of other orebodies to which my attention was called in this region are usually about the same, but the dips are generally more nearly vertical, but inclining toward the south.

No thorough examination of this district of Alaska can possibly be made unless the entire season is devoted to such work, and then it may be found that too little time has been allowed to cover the ground, even from Elliott creek to the Bonanza mine, to say nothing of the White, Alsek, and Tanana districts.

The altitude of the river valleys varies from about 1000 ft., which is the elevation of the Copper River valley near the mouth of the Tonsina river, and 2800 or 3000 ft., which is the elevation of the Lakina valley near the headwaters of that river. The mountain ranges reach elevations from about 5000 ft., the summit of the Kushkilina range, to some 7000 or 8000 ft. at other summits, which are accessible for exploration, while of course Mt. McKinley, Wrangel, Hood, and Blackburn reach much greater altitudes.

The Production of Copper.

By L. C. Graton

*Of the 917,805,682 lb. copper produced in 1906 by the smelters, 15,132,562 lb. were derived from the re-treatment of materials which had been subjected to reduction in previous years—namely, old slags, tailings, furnace linings, and the cleanings from old smelter sites. Of the 404,496 tons of this material, a great part was slags and tailings; consequently of low grade and capable of treatment only because of metallurgical advances. The average yield from this old material was about 1.8%. The remainder of the smelter output, 902,673,130 lb. copper, was the yield from about 19,743,000 tons of ore, the average yield per ton being about 43 lb., or 2.15%. The 1,700,000 tons of ore mined and treated primarily for values other than copper, furnished a very considerable portion of the total copper production. If these ores are left out of consideration, the yield of the 18,000,000 tons of ore mined expressly for copper was close to 50 lb. per ton, or 2.5%. The native copper ores of Michigan, which in 1906 yielded only 1.26%, being excluded, the remaining copper ores of the country yielded an average of about 73 lb. per ton, or 3.65 per cent.

Copper ores yielded 271,197 oz. gold, and 15,880,870 oz. silver, according to mine reports for 1906. This is an average yield for the 18,000,000 tons of copper ores of about 0.015 oz. gold, and 0.882 oz. silver per ton. If the Michigan ores that do not carry silver, amounting to about 8,000,000 tons, are excluded from this calculation, the copper ores which actually contained precious metals yielded an average of about 0.027 oz. gold, and 1.588 oz. silver per ton.

Pyrite smelting, which has grown rapidly in recent years, owing not only to metallurgical advances, but to the marked increase in mining of pyritic copper ores, offers, because of its high requirement of silica flux, an advantageous method of treatment for these silicious gold and silver ores which require or permit smelting. Copper is thus fast replacing lead as a collector of the precious metals in the smelting of dry ores. In consequence, the gold and silver product of all domestic ores treated in copper smelters was considerably in excess of the yield from the copper ores alone. This product in 1906, according to data partially incomplete, was, gold, 484,000 oz.; silver, 21,110,000 oz. The 1,700,000 tons of ores other than copper ores which were smelted in copper furnaces furnished, by difference, about 213,000 oz. gold, and 5,226,000 oz. silver, an average of 0.125 oz. gold, and 3.07 oz. silver per ton—a decidedly higher average than that of the copper ores.

All this gold and silver was recovered as such only on electrolytic refining of the pig copper. A part of the output of the Morenci-Metcalf and Bisbee districts in Arizona, and of the Ducktown district of Tennessee, and small quantities from California, New Mexico, and Missouri are too low in precious metals to make the electrolytic refining of this copper profitable. With these exceptions, practically all the blister copper of the country, as well as a noteworthy portion (over 10%) of Lake copper, is subjected to this separation by electrolysis. In all, about 669,000,000 lb. domestic copper carrying gold and silver, and requiring electrolytic refining, were produced in 1906. Ores containing sufficient quantities of both copper and lead to be classed as copper-lead ores supplied 59,371 oz. gold and 6,815,678 oz. silver, according to reports from the mines. Practically all these ores were smelted in lead furnaces, and the greater part of the precious metals was recovered in lead bullion, copper being collected as matte and further treated in copper furnaces.

Copper mines in general do not fall in the class of "poor man's mines." Ordinarily the ore is not amenable to any simple method of reduction, and is of so low a grade as to preclude very extended hauls to existing reduction plants. Much money must first be spent in extensive development of the orebodies. The company must usually expect to build its own smelter or mill, and to operate on a large scale to achieve low cost of extraction. In consequence of these conditions, most of the important copper mines of the United States are in the hands of strong companies able to advance the capital required at the start.

In few other industries is the tendency toward centralization and combination better illustrated than among the copper-producing companies. Fully 720,000,000 lb. of the 1906 output was produced by four operators—the Amalgamated Copper Co., with its many allies and associates; the Calumet & Hecla Mining Co.; W. A. Clark; and Phelps, Dodge & Co. With the entrance into the producing ranks of the Utah Copper and Boston Consolidated companies, the Ely mines, and the Dairy Farm mines, and with the expected increase in production of the Cactus and Mammoth mines, this list of four companies will be augmented by the United States Smelting, Refining & Mining Co., the Guggenheim interests, and the Newhouse interests. Four of these seven concerns either maintain or are closely associated with selling agencies.

Production at the principal mines is on a truly enormous scale, with ore tonnage and copper output of individual mining units ranging up to more than 2,000,000 tons and 100,000,000 lb., respectively, with single milling plants of a daily capacity up to 8000 tons, and with smelting plants turning out annually 90,000,000 to 175,000,000 lb. copper each. To the magnitude of these operations almost as much as to the abundance of her natural resources does this country owe her pre-eminence as a copper producer, with a record of over half the world's production.

*Abstracted from 'Mineral Resources of the United States,' U. S. Geological Survey.

Detonators for exploding dynamite consist ordinarily of a mixture of mercury fulminate, and potassium nitrate or chlorate, placed in a copper capsule; when the cap is to be fired with a fuse, the fulminate is covered with shellac, collodion, thin copper foil, or paper, and the end of the capsule is left open to receive the end of the fuse.

Bureau of Mines.

A bill to establish, in the Department of the Interior, a Bureau of Mines, was introduced on January 6 before the House of Representatives by Mr. W. P. Englebright, of California. It reads:

SECTION 1. That there is hereby established in the Department of the Interior a bureau to be called the Bureau of Mines. The chief purpose of this bureau shall be: (1) The acquisition and diffusion among the people of useful information concerning the mine and quarry industries, and the more efficient and safer methods of extracting and using the mineral products of the United States, its territories and insular possessions, with a view to the betterment of these industries, the improvement of mine conditions, the prevention of accidents, lessening the waste of materials, the improvement of milling and reduction of ores and securing a wise conservation of the fuel and other mineral resources of the nation; and (2) the investigation of materials used in construction, fuels, metals, and other mineral materials belonging to, or for the use of, the Government of the United States and how these can be used most efficiently.

Sec. 2. The President is authorized to appoint, by and with the advice and consent of the Senate, a Director of said Bureau, who, under the Secretary of the Interior, shall be charged with carrying out the purposes and provisions of this Act, and who shall receive a salary of six thousand dollars per annum. The Director of said Bureau, with the approval of the Secretary of the Interior, shall appoint for service in the city of Washington or elsewhere, the necessary experts and regular employees; and by authority of the Secretary of the Interior, he may employ such additional temporary experts and assistants as may be found necessary for like service.

Sec. 3. The Director of said Bureau, with the approval of the Secretary of the Interior, shall establish a station for the investigation of explosives and other matters pertaining to mine accidents, and such additional testing stations, laboratories, and offices, and he shall conduct such inquiries and investigations as may be required in carrying out the provisions of this Act. In establishing said laboratories or testing stations or for use otherwise in carrying out the provisions of this Act, the Secretary of the Interior may accept from any State, territorial or municipal government or corporation or person, any site, building, equipment, or fund which he may deem it proper to accept; provided, such acceptance shall be reported to Congress, and shall not be considered as binding the Government of the United States beyond the appropriations made by Congress; and the President is authorized to transfer to the Department of the Interior, for use in carrying out the purposes of this Act, any grounds or buildings or equipment belonging to the Government, and which he finds unnecessary for other public uses.

Sec. 4. The Director of said Bureau shall conduct, free of charge, such tests or investigations as may be needed concerning the nature and most efficient methods of utilizing materials used in construction, fuels, metals, and other mineral materials belonging to or for the use of the Government of the United States, except that in cases of extended investigation for any other branch of the Government service the cost may be borne in part or wholly by said branch. He may also conduct for the authorities of any State, territory, insular possession, or municipality, corporation, or other party, at cost, under regulations to be prescribed by the Secretary of the Interior, similar tests or investigations, especially when these are connected with building or construction works involving public safety, the improvement of mine conditions, or prospecting on public lands. In conducting inquiries herein authorized, the Director and his authorized assistants are hereby given the same power and authority in connection with the collection of statistics and other information as that given the Director and employees of the Census Bureau.

Sec. 5. The said Bureau is further authorized to cooperate with other branches of the Government service, or with the authorities of any State, territory, insular possession, or municipality in investigations germane to the purposes of this Act, in such manner as to avoid unnecessary duplication of work or expenditure; and in this work either co-operating party is authorized to pay the expenses or salary, or both, of any employee of the other party during the continuance of such co-operation. All money received from other parties as deposits to cover the cost of work by this Bureau shall be covered into the Treasury of the United States as part of a special fund; and all moneys received as contributions toward co-operative work herein provided for shall be covered into such special fund. The moneys in this special fund are hereby appropriated and made available for such purposes until expended, as the Secretary of the Interior may direct, for the payment of the cost of such work or a share of this cost as per agreement, and for refunds to the contributors of amounts paid in by them in excess of the cost or their share of the same.

Sec. 6. In connection with the inquiries hereby authorized into the mine and quarry industries and the most efficient methods of utilizing mineral products in foreign countries, the consular officers of the United States, when directed by the Secretary of State, shall make for the use of this Bureau such special inquiries and reports bearing on these subjects as may be requested; and special examinations into such conditions may be made in foreign countries by the technical experts of this Bureau when in the opinion of the Secretary of the Interior the same may be necessary and proper.

Sec. 7. The President may appoint as members of a National Advisory Board for the investigations of this Bureau (1), the heads of such other bureaus of the Government as conduct extensive construction work or purchase extensive supplies for the Government, to be tested by this Bureau; and (2) other persons experienced and skilled in one or more of the several lines of experimentation or industry to which the work of this Bureau relates, as he may deem advisable. This Board shall submit to the President through the Secretary of the Interior once each year, or from time to time as occasion may require, recommendations concerning the work of the Government or the conditions in the country to which these investigations relate. The members of this Board shall serve without compensation, but shall be reimbursed for expenses incurred in attending its meetings or inspecting its work, as may be authorized by the Secretary of the Interior.

Sec. 8. The Director of said Bureau shall prepare and publish, in editions of sufficient size to meet the demands for the same: (1) Annual reports embracing an administrative statement, and a summary setting forth the nature and extent of mine operations and production, the nature, causes, and prevention of mine accidents, and other results of inquiries and investigations conducted under the provisions of this Act; (2) bulletins, circulars, and special reports, each embracing the results of inquiries or investigations into one or more of the subjects covered by the provisions of this Act; the same to be published and distributed free of charge, as promptly as possible, among the people interested in these industries.

Canadian Industrial Disputes Act.

Written for the MINING AND SCIENTIFIC PRESS
By FRANK A. ROSS.

While the Canadian Industrial Disputes Investigation Act of 1907, popularly known as the Lemieux Act, is in most respects as novel and prudent as President Eliot declares it to be, and although it deserves all the good things said of it in December *McClure's*, yet those of us that operate under it know that in some of its practical and unexpected effects it is very burdensome to the employer.

The crucial test of any statute comes with an attempt to enforce its penal clauses. If this fails with respect to all parties, then the statute itself becomes a dead letter; but if a penal clause is enforcible as to one party and not as to the other, then the statute instantly menaces the first party at the hands of the second, and this is precisely what happens in the case of the Lemieux Act. It is operative as to responsible employers but is practically inoperative as against irresponsible employees. President Eliot, himself, evidently saw this feature of the Act since, in his conclusions, he says that it is an interesting question how the penal clauses of the Act are to be enforced, although it would appear from the remarks following that he had reference more to legal procedure than to punishment. The Lemieux Act is premature. Admirably conceived, formulated with cold impartiality, its influence over the industrial world will be inversely proportional to the degree of immunity from prosecution which, in practice, the irresponsible employee will be found to enjoy. Stated another way, there is nothing in this Act that makes it practically possible to penalize men that own nothing and that are constantly changing their residences. There is nothing in its mandatory strike-clauses to frighten the nomadic miner, for every mine-manager knows that when he wishes to quit work, he simply quits and that is all there is to it. He has no need to 'strike' for he is full of plausible excuses, born of a cosmopolitan experience, and his 'inalienable rights' are strongly safeguarded.

All this was clearly illustrated during the late unpleasantness at Crow's Nest Pass and, only a few days ago, in the Boundary country of British Columbia. In the latter district, the practical effect of the Lemieux Act was to prevent all reference to wages by the managers, before shutting down the numerous copper mines and smelting plants in their charge. It had been rumored that the men would reject any proposal involving a return to the old scale notwithstanding that the miners of Butte, Montana, had already done so on November 1, in strict accordance with their agreements which were based upon eighteen-cent copper. The men of the Boundary claimed that they, themselves, had signed no such agreement, although it was well known that the Boundary scale depended entirely upon that of Butte and it was a matter of common belief that both hinged upon the price of copper.

By the terms of the Lemieux Act, therefore, had any attempt been made by the managers to close down their plants after a proposition to reduce had been rejected and before a Commission under the Act had heard all the evidence in the case, it would have laid each of the companies liable to a maximum fine of $1000 per day, and they were all thoroughly responsible. There was nothing to be done, therefore, except carefully to avoid all reference to wages and the companies, confronted by the alternative of indefinite delay incident to official investigation or of a complete shut-down pending efforts for better terms, chose the latter. Within a few hours, every wheel in the district had stopped, immense plants were boarded up and thousands of men, over-confident of their power, suddenly found themselves without employment.

The fate of the Boundary country made a deep impression upon the men of Rossland, for on November 26, by a referendum vote, they decided to accept the old scale and so announced their decision to the managers although the latter had made no move beyond intimating unofficially that under the scale then existing all work would stop on December 1. Fear of the Lemieux Act thus brought about two diametrically opposite results, in the one case paralyzing all business and in the other, a few miles away, adding to it, through a return of confidence and a removal of suspense.

But in the Similkameen division of British Columbia this same fear of consequences to responsible employers brought about still another condition of affairs for, all official discussion of wages being barred, the men of this section ignored the wise procedure of the Rossland miners and, relying upon the 30-day clause for another month of high pay, refused to return to the scale now made general by the Rossland vote and thereby imposed an unjust loss upon their employers whom they knew to be helpless, since a shut-down, as in the Boundary case, was inadvisable.

These examples, in contra-distinction to those cited by President Eliot, will serve to show the other side of the Lemieux Act; and while they certainly indicate a weakness somewhere it may be doubted whether the weakness lies in the Act itself rather than in the absence of complementary, or preparatory, legislation necessary to give the Act full force and effect.

With this possibility in mind, the Industrial Disputes Investigation Act of 1907 was, in the beginning of this article, characterized as premature. No one who has ever been party to a serious industrial dispute will hesitate to advocate legislation that will render organized labor equally responsible with its employers, legally and financially; nor will he for a moment doubt that what is most needed to complete the usefulness of the Act in question is another act, or series of acts, compelling organized labor to incorporate, to own property, to maintain a guarantee fund as indemnity against loss to the employer from ill advised or willful acts of employees or their accredited representatives. Stated otherwise, it is high time for politicians to cease dodging this issue and for irresponsible trade unions to perfect their organizations to such an extent that each individual member thereof may go into court with clean hands, equally responsible with his employer, in every way.

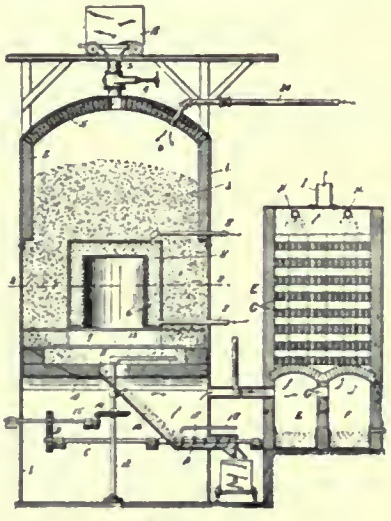
Nor is this at all impracticable or difficult. Combinations of labor are henceforth as inevitable as combinations of capital; but it must never be forgotten that, as the late John Marshall said: "It is not safe to trust to human cupidity when it has the opportunity to aggrandize itself at the expense of others."

To require labor organizations to incorporate, therefore, would result in immediate improvement in their internal discipline; and each member, being made to feel his personal responsibility in the acts of his representatives, would soon learn to chose his leaders for their business ability and integrity alone and not for oratorical powers or physical prowess. When this happens, as it must, and when labor leader meets business manager on an equal footing, each representing responsible interests and each capable of understanding the other, then will all industrial disputes begin to solve themselves almost automatically if held in check by laws as prudent and comprehensive as the Lemieux Act. But without this equality of legal and financial responsibility it is useless to pile statute on statute for, as Kipling says, it is only when the pocket book is touched that 'things happen.'

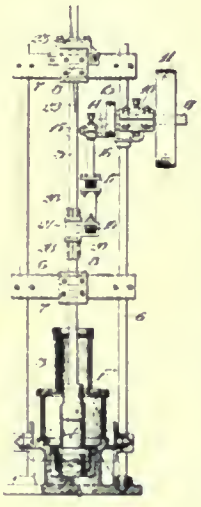
MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

PROCESS OF CHLORIDIZING ORES.—No. 873,309; John E. Greenawalt, Denver, Colo.



No. 373,309



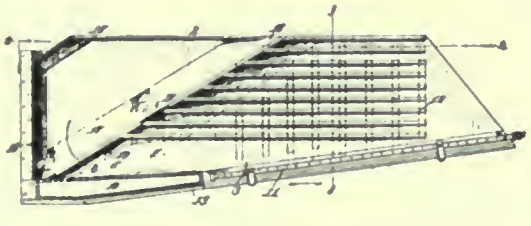
No. 873,323

The herein described chloridizing process which consists in introducing the heated ore into a chloridizing chamber, passing the ore through said chamber and into and through a cooling zone, and simultaneously passing a stream of chloridizing gas through the ore. A chloridizing process which consists of chloridizing the ore by means of sodium chloride by heating in a suitable furnace and then introducing the ore while still in the heated condition into a closed chamber and finally passing a stream of chloridizing gas through the ore.

STAMP-MILL.—No. 873,323; Francis I. Matthews, Oakland, Cal., assignor to Oakland Stamp Mill Co., Oakland, Cal., a Corporation.

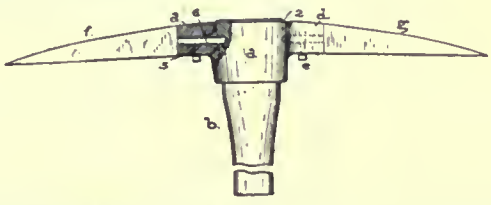
In an ore crushing mill of the character described, a guided rising and falling stamp stem, collars adjustably fixed upon the stem, a sleeve located between the collars through which the stem is loosely turnable, said sleeve having an offset horizontally channeled box, a segmental bow spring, a crank shaft and connection between the crank and the centre of said spring, links connected with the ends of the spring, a flexible yielding band extending between the said links and loosely through the channel of the box, a fixed guide, a transversely movable casing carried thereby, through which casing the stamp stem passes, a clutch mechanism carried by the casing, a spirally grooved sleeve fixed to the stamp stem, and corresponding lugs actuated by the clutch mechanism and engaging the grooved sleeve.

ORE-CONCENTRATOR.—No. 874,364; Ulysses S. James, Newark, N.J., assignor to James Ore Concentrator Co., a Corporation of New Jersey.



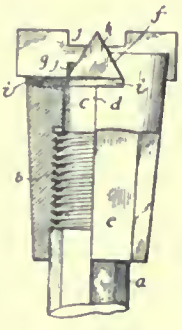
An endwise reciprocatory ore concentrating table having a concentrating portion flexibly joined along a line diagonal to the line of motion of the table and a slime portion, the concentrating portion being adapted to concentrate the pulp and the slime portion being adapted to receive the slime from the pulp and having an inclined ledge extending obliquely thereacross, provided with a face inclined upward toward the tail of the table and oblique to the line of motion thereof, combined with means for adjusting said concentrating portion angularly with respect to the slime portion.

MINER'S PROSPECTING TOOL.—No. 874,730; Dominik Bolderl, Oakland, California.

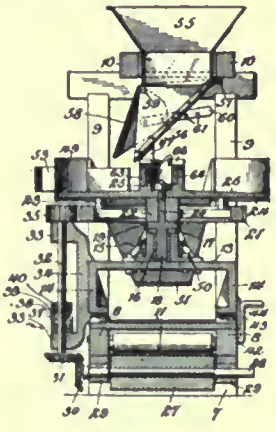


The herein described prospecting tool comprising a head having a tapering central socket, a handle removably fitted thereto and provided with cavities, and bosses on the head having squared ends, each boss being provided with a socket extending longitudinally from its end to the central socket, a detachable tool-point or member and a tang secured to the inner end of the tool and adapted to slide into a longitudinal socket, the tang being of a length greater than the socket and arranged to extend therethrough and into a cavity in the handle.

ROCK-DRILL.—No. 874,455; Frederick V. W. Swanton and Burt Price, Braamfontain, Johannesburg, Transvaal.



No. 874,455



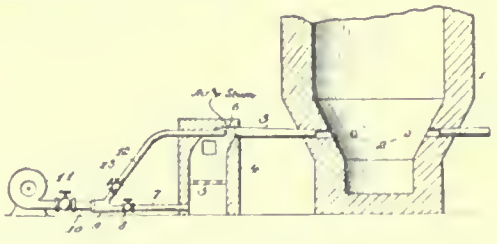
No. 873,748

In a rock-drill, a bit stock having undercut grooving on the face, triangular cutting means located in the grooved face and having an interlocking relation with each other and means for applying pressure to the underside of such cutting means to lock the same in position.

ORE-FEEDING MECHANISM.—No. 873,748.—Marshal Henderson, Doe Run., Mo., assignor of one-third to Ulysses Hawk, Doe Run, Missouri.

In feeding mechanism of the character set forth the combination with a downwardly and outwardly inclined table having a substantially upright axis of rotation, of a circular series of upstanding teeth carried by the central highest portion of the table, a vertically movable spout located above the table and engaged and operated by the teeth, and means for rotating the table.

METHOD OF SMELTING ORES.—No. 874,336; John C. Hardie, Helena, Montana.



A step in the reduction of a mass of ore in a chamber which consists in causing a direct blast of atmospheric air containing steam to enter directly into a gas generating chamber and to direct to the ore a carbon dioxide gas formed from the admixing in the upper portion of said generating chamber of a blast with a carbon monoxide gas formed by passing a blast of fluid containing air through an incandescent body of fuel.

A Mine Signal System.

The bell-line used for signaling in shafts is a crude affair; a miner is never absolutely sure, when signaling from a deep level, say the 1,000-ft., that the signal has been received as intended. Yet the bell-line must be retained for emergency use, for instance, for signaling from the cage, while inspecting the shaft or in case of accident, while men are on the cage; also in case the other system of signaling is temporarily damaged. But the method of rope-signaling is too slow and clumsy for even shallow shafts where fast hoisting is being done. In consequence, electric bell systems and electric flash systems of signaling are now generally used at mines. In some mines these are simply push-buttons and an electric switch in the lighting system of the mine to make and break the circuit.

These are too crude affairs for work in wet shafts, for water soon gets into the splicings of the wiring system and short-circuits result, with their attendant vexatious delays. Consequently, improved electric signaling systems combining the bell and the flash systems have been invented for this purpose. The Richmond Mine Signal System is one of these; it is used at the Ahmeek and the Mohawk mines in Keweenaw county, Michigan. At the Ahmeek mine the method of operation is by means of signal-boxes or semaphores in parallel throughout the mine, one signal-box being placed at every level or station from whence it is desired to signal. The depressing of a heavily constructed push-button, projecting from the front of the signal-box, operates the system. Through the construction of this push noticeable sparking is prevented. The signal-box contains a semaphore lens, a small electric lamp, and an audible signal; the whole is protected by a hood from wall-drippings and falling rock.

In the ore-house or on the dump there is a suitable bell which operates in unison with the signal underground and serves to notify the top-man that the skip is coming either with ore or waste rock. At the collar of the shaft there is also provision for a local circuit. The switch in this circuit operates a solenoid gong in the hoist-house, termed the 'surface gong.' The surface gong is controlled from the landing station as well as from the collar of the shaft. The mine system, distinct and separate from that of the surface, is necessary owing to the use of balanced skips.

The equipment consists of two semaphores, one on each side of the hoisting drum and in close proximity to the chalk marks on the rim of the drum. A relay switchboard for testing all lines is placed handy to the engineer's station. Suspended in front of him are the mine and surface gongs, which are operated by solenoids. At his hand is also a signal-box like that used underground; with this he can signal back when so desired. This ability to signal back to the underground operator is a great advantage. When the man below depresses the button, the call comes in at the hoist-house; the receiving mechanism then operates a relay and flashes back to the sender the identical signal that he has given. This is purely automatic and it is impossible to receive a back signal unless the call is received in the hoist-house. The underground operator watches his signal-box to see that his calls are correctly transmitted. In case of a mistake in pushing, he can instantly nullify the previous signal by a proper code. The engineer receives the signal from below in the following manner: With the pressing of the button on his signal-box by the man below, the relay in the engine-house energizes the solenoid gong, and sets a red light glowing in each semaphore on the rims of the drum. Releasing this button underground drops the plunger, puts out the red light, and causes a green light to take its place. This constitutes 'one bell.' The green lens shows the hoist-operator that all is in working order; the green light stays on until a call is given.

All signal-boxes on levels work in unison and show men on other levels when the system is in use and they govern themselves accordingly. The wires are placed in a specially prepared iron conduit, ¾-in diam., which protects the wires from water and abrasion. Three wires, not over No. 14 in size, are used.

At the Mohawk No. 5 shaft an improvement, designed by the inventor, consists of a small, compact, pocket telephone, which every mine captain and shift-boss carries in his pocket. This is about the size of a tobacco box. The telephone has a plug and cord attached. Every signal-box is provided with a hole underneath the box; by inserting the plug into this socket, connection is made with 'central' (the hoisting engineer); central can then, if it is desired, connect the underground system with the surface telephone lines; then the person underground can talk with any of the departments of the company at surface. The method of calling a man underground is through the engineer and his signal-box. All telephone troubles are confined to the telephone sets; another set can be issued while the broken one is being repaired.

The patent rights to this system are controlled by The Richmond Co., of Oshkosk, Wisconsin.

Commercial Paragraphs.

W. B. HAMMOND, 29 Broadway, New York, has succeded Herman Nieter as sales agent for the Hammond Iron Works of Warren, Pennsylvania.

ROBERT W. HUNT & Co., inspecting and consulting engineers, have established a branch office and chemical laboratory at St. Louis, Mo., under the charge of Charles W. Gennett, Jr.

THE ELSPASS ENGINEERING & MINING MACHINERY CO. of Denver, recently shipped a complete mill, including Elspass mill, Pierce amalgamators, boiler, engine, and full equipment to Round Mountain, Nevada.

THE AMERICAN MILL WORKS, of Aurora, Ill., have issued a new and attractive bulletin (No. 104), describing the construction of their centrifugal pumps and explaining the varied adaptations of this useful piece of machinery.

THE NEW YORK ENGINEERING CO. has recently secured a contract from F. B. Vrooman for a steam driven gold dredge to operate on the Hootalinqua river, in the Yukon Territory. This dredge will have a capacity of 2000 yards per day, and it is expected that it will be in operation by the early part of the summer. This company makes a specialty of building gold dredges, and has been successful in securing many contracts of late.

Catalogues Received.

THE INDIANAPOLIS SWITCH & FROG CO. of Springfield, Ohio, has issued a catalogue describing its manufactures which include crossings, frogs, switches, stands, and accessories.

THE DEISTER CONCENTRATOR CO., of Fort Wayne, Indiana, has issued a catalogue entitled 'The Deister Ore Concentrator No. 2.' The concentrator described is adapted for handling both fine and coarse feeds.

THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY issues the 'Catalogue' for December, 1907, containing lists of the officers and students, with a statement of the requirements for admission, and a description of the courses of instruction.

THE VULCAN IRON WORKS of Wilkes-Barre, Pa., has issued a well illustrated catalogue describing its elevating and conveying machinery and general colliery equipment, including hoisting engines, locomotives, boilers, hoisting crabs, cages, and screens.

CHALMERS & WILLIAMS of Chicago now have ready for distribution 'Section L' of their general catalogue. It describes the 'Gold and Silver Mill Machinery' which this firm manufactures, including the Kennedy gyratory crusher, overhead crawls, ore-bin gates, bucket elevators, and revolving screens.

THE special three-months course for mining men at the School of Mines of the University of Washington, at Seattle, begins this winter on Jan. 6. There are no charges for tuition, the only cost being for materials actually used and for books. The equipment in stamp-milling, concentrating, assaying, etc., is complete.

Editorial.

ENGINEERING PROBLEMS are finding solution every day in mines, but it is rarely that a lucid account of them is forthcoming. To Mr. Henry Boursin we owe an excellent description of the manner in which a shaft was sunk through bad ground by resort to puddling. Only experienced mine superintendents can appreciate the nature of the difficulties overcome and the skill required for this uncertain work.

IRON AND STEEL MANUFACTURES exported from the United States in 1907 were worth close to 200 million dollars, as compared to 63 millions in 1897, and 16¼ millions in 1887. This affords an eloquent commentary on the growth of an "infant industry" under the kindly protection of a high tariff. Of the total exports of domestic merchandise, iron and steel manufactures formed 5.8 per cent in 1897, as against 10.8 per cent in 1907. Machinery constituted one-half of this class of export, the total value of machinery exported being $87,500,000.

PANAMA has gained vastly in importance by reason of the great waterway now under construction across the isthmus, and this Central American State has lately become of more interest to the world at large than at any period since the day when Balboa "stood lone upon a peak in Darien." The mineral resources of Panama are largely unexplored, mainly because transport is lacking in the interior, and the tropical vegetation makes prospecting almost impracticable. Any fresh information is welcome, and when it is conveyed in a plain straightforward manner, it is particularly desirable. For these reasons the article by Mr. Scott Turner should prove useful.

OUR DENVER CORRESPONDENT refers to the increased activity at Cripple Creek, and to the numerous new leases granted on mines in that district by reason of an influx of miners from Nevada and Utah. This is one manifestation of the fact that the depression in the prices of the base metals has tended to enhance the attractiveness of gold mining. Unquestionably a profitable gold mine is the most desirable of all enterprises today, for the owner of it can turn his product into coin by sending the metal to the nearest mint, so that he is independent of banks, and even of smelters, if his ore be docile to stamp-milling or cyanidation. He pays for his labor and supplies with the metallic product of the mine, and this product has a fixed value, in terms of the monetary unit, while being actually enhanced as relates to the amount of it exchanged in the purchases of labor or machinery required for the operation of the mine. We expect to see an intensified interest in gold mining,

and a notable stimulus given to the metallurgy of refractory gold ores. The hunger for gold is more acute today than at any time in human history.

CYANIDATION as applied to the silicious ores of Nevada is sure to gain in importance during the current year, therefore we are glad to publish the interesting and comprehensive letter of Mr. Lochiel M. King. He advocates dry crushing and roasting of the ore, instead of wet crushing and amalgamation, before cyanide treatment; and in support of his contention Mr. King quotes freely from a number of tests made on Goldfield ores. In regard to the presence of gold as a telluride, we are compelled to accept the evidence quoted by Mr. King, which is not necessarily contradictory to the statement of Mr. Edgar A. Collins; the first of these gentlemen refers to the Mohawk ore, while the second wrote concerning the ore produced from the Combination mine. This is not the first time that two neighboring ore deposits have exhibited an important difference in their mineralogical character. As to filters, it is noteworthy that the Merrill filter-press, so successful in the Homestake slime plant, is to be adopted in the new mill of the Goldfield Consolidated Mines Company.

Prospecting for a Meteorite.

IN the desert of northeastern Arizona, near the Canyon Diablo, a branch of the great gorge of the Colorado, there is a crater-like depression of mysterious origin. Travelers have invented explanations, and scientific men propounded theories explanatory of this curious hole. It is circular in form, nearly three-quarters of a mile in diameter at the top, about a quarter of a mile across at the bottom, and 600 feet deep. The country consists of horizontal strata of sandstone and limestone; on the border of the depression these rocks have been shattered, and the particles of quartz in the sandstone have been partly fused. The material ejected from this excavation lies scattered over the surrounding desert. Small masses of native iron have been found in the talus within the pit, and these have the appearance of meteoric fragments. Indeed, Mr. George P. Merrill, curator of the National Museum, made an investigation of the curious occurrence, and suggested that it may have originated from the impact of an immense meteorite. Others apparently shared this view, for a company was formed to prospect for a body of iron big enough to constitute a profitable mine. Holes were drilled through the floor of the pit and, after penetrating 600 feet of débris, the drill reached solid rock. No masses of iron were discovered. The enterprise collapsed, and the facts ascertained warrant a new theory. Another geologist, who has recently visited the locality, suggests that the depression is really what it appears at first sight to be, namely, a crater. It is true, no volcanic rock occurs adjacent, but this may be explained on the supposition that an explosion of steam blew out the rock and scattered the fragments over the neighboring country. The presence of sedimentary rock under the débris raises a difficulty, but it is suggested that the drill-holes necessarily explored only a small portion of the area underneath, and small passages may have existed by which the superheated steam reached a horizon at which the sudden relaxation of pressure led to a violent explosion. It is a significant fact that some of the strata at the rim of the crater are bent upward, indicating the action of force from below, instead of impact from above. While the meteorite story appears more wonderful than that of crater formation by the explosive force of superheated thermal waters, the latter would be quite as remarkable a manifestation of nature's unrest.

Professional Customs.

THE questions offered in good faith by a young mining engineer two months ago have now been answered by no less than 25 mining engineers of varied experience. Our young friend has got all the illumination he needs and if, in his future career, he errs in the special matters discussed, it will not be for lack of counselors. To some of the cynics the discussion may have seemed unnecessary, for the replies to the ten questions are fairly obvious. Nevertheless, a good deal of character is to be read between the lines and if most of the answers indicate a decided honesty of purpose, it is also significant that none of those whose methods are contrary to established rules, dared to avow them in print. The comparatively simple matters discussed may not appear of monumental importance, but we venture to hope that the consensus of professional opinions will be beneficial to the younger engineers. The older men are beyond the ductile stage and the best they can do is to train their sons to observe a code better than their own, for unless we advance, why move at all?

The three chief points touched upon in this discussion of professional customs have been (1) the nature of the agreement with the client, (2) the character of the expenditures to be debited, and (3) the nice question as to incidental personal speculation. It is not possible often to choose your client; the choice is usually on the other side. Engineers have to take business men and speculators much as they find them. Consequently, any man of experience can recall contracts that were broken and reports that were never paid for. But such mishaps are less common nowadays than they were twenty years ago; in part, by reason of the greater publicity incidental to dishonorable conduct and, in part, because of the larger amount of money spent in preliminary investigations. Whether a young engineer can get a definite agreement with his client or not, he can at least obtain an exchange of telegrams or letters, sufficient to constitute a contract. Two bits of advice may be offered in this connection; never undertake work for a personal friend without a definite agreement in writing, for a misunderstanding with a friend is worse than the loss of a fee; and, secondly, never make an arrangement with a director, as such; let it be with the individual or the company. If things go wrong, a weak man—not to mention a dishonorable one—will waive responsibility and pass it on to his com-

pany, and the other directors may repudiate the transaction. Therefore, either make the director personally responsible or else his company, with the proper endorsement of the officials empowered to act for the said company. By so doing, you may avoid the experience of falling between two stools. Of course, we could give the advice not to do business with the man you cannot trust, but that is putting the smell before the automobile; every client is presumed to be honest until proved otherwise. Backsight would be better than foresight, if it were not back-sight. So the advice must be modified by saying: Have nothing to do with people known to be tricky, as long as a client of a better class is available. But beggars cannot be choosers and if the only client on the horizon is a spoofer, get him to advance the amount of your expenses, at least, and exact some legal assurance for the fee itself. If he really wants your professional advice, he can be made to pay for it. Luckily, men themselves tricky often know enough to set a high value upon an honest opinion. So much for that.

Now, as to traveling expenses and incidentals. The question as to the propriety of traveling second-class and charging for first-class accommodations, may have seemed ingenuous, but it has the merit of going to the root of the matter. Of course, no engineer should charge a cent more than he spends and in traveling he should put his client to exactly the same expense as he would himself, if the journey were made on his own recognizances. Engineers travel first-class simply because time and health are alike conserved by so doing; moreover, as has been suggested, by traveling first-class they are apt to meet other people, such as fellow engineers, possessed of information useful for the purposes of the particular investigation or engineering work to be undertaken at the end of the journey. It is not necessary to itemize every petty expenditure, but an engineer should be prepared to give satisfaction as to the manner in which the client's money was spent. Many engineers count the money in their pockets when they start on a professional journey and count the balance remaining when they return, debiting their client with the difference. If careful note is made of any expense not properly debitable to the client, this method is fair, for the client should pay any costs arising from the incidents of the journey, that is, expenses not incurred by the engineer when at home. But such a net result ought to be checked by a statement, not only for the satisfaction of the client, but of the engineer himself. Customs differ in this matter and, naturally, much will depend upon the standing of the engineer and the importance of the work undertaken. Good sense, not to mention good judgment, is needed. A man who makes a fool of himself or proves tricky in these smaller affairs is not likely to win a reputation for integrity or trustworthiness. We know of an engineer who examined a mine in Australia recently and spent eight months of time, besides £10,000 in expenses, not including his fee, and yet the result of the work was deemed satisfactory to the company that footed the bills; but an untried man that had taken half as long and spent one-tenth of the money in expenses, would have been severely criticised, simply because such a performance on his part would have been difficult to justify. Be true to yourself, do not juggle with your sense of honor, and you are likely to conserve the interests of your employer.

This is particularly true of the next problem, namely, that relating to speculation in the shares of the mine you examine, the taking of options, and the acceptance of incidental engagements for other people when visiting a district for a specific client. To young men in doubt as to these points, we say, unhesitatingly: No. Go to a mining camp with a single purpose, accomplish it to the best of your ability, and return home to write your report. Listen not to the lure of the share market or the promptings of the promoter. Speculating in the shares of mines with which you are in any way connected is unprofessional, though professional men do it. An engineer ought no more to dabble in stocks than a broker. Both do it, but many wrongs cannot make a right. Whatever the ethics of the problem, there can be no question of the expediency as it affects young men. A seasoned man may take a glass of brandy after his dinner, a stripling is spoiling a perfect alimentary system by doing so. That way lies intoxication. To young engineers the stimulant of a share gamble is the most insidious peril that they face in the early years of their career. It has spoilt many fine fellows; it has ruined twenty times as many good engineers as it has enriched. And as to the taking of options and dealing in mines while under engagement to do a specific bit of work, that also is best eliminated from the program. It leads to complications, it may cause a division of duty, and at best it is no part of a young engineer's prerogative. A simple way of avoiding wrongdoing is never to do an act the correctness of which you yourself question. When you are young you will decide against yourself, if honorable; as men grow older their sense of nicety in such matters is apt to be dulled by contact with the business world, in which right and wrong are divided not by a line but by a debatable tract large enough for the manœuvres of a cavalry regiment. "But," says the alert young man who wants to be rich and successfu, deeming the two synonymous, "if I observe all these fine points of the game, I can never make money or utilize my opportunities." To which we reply that tricky, or self-seeking, or disloyal young engineers are soon rated at their proper worth—less than nothing—and that while some of them have been known to succeed in the winning of wealth, such instances are exceptional and in their final history are pitiable, while on the contrary most such men lose the confidence of their clients and usually change their occupation. Virtue may not always be rewarded and dishonesty may occasionally flaunt its winnings—it is not for us to sermonize—but it is not necessary to be a Methuselah to see that among a body of educated scientific men such as that of mining engineers and metallurgists, any success that involves loss of self-respect and the absence of goodwill from others is as a Dead Sea apple, as a sawdust doll, as grit between the teeth.

Personal.

MARK L. REQUA has gone to New York.

MARK R. LAMB is now at Guadalajara, Mexico.

FRANK R. SHORT is now at Carson City, Nevada.

R. H. ROBERTSON has returned from South Africa.

G A. DENNY is on his way from London to Mexico.

B. M. NEWCOMB, of San Francisco, is at Mexico City.

E. M. HAMILTON is now at the Butters Salvador mines.

T. H. JENKS is traveling in Sonora and Sinaloa, Mexico.

BENJAMIN T. LOEB has opened an office in the City of Mexico.

A. A. HEER is manager of the Little Florence mine at Goldfield.

EMILE R. ABADIE has an office in the Pacific Bdg., San Francisco.

BEN S. REVETT visited Goldfield on his way from San Francisco to Denver.

FRED. B. REECE is with the Homestake Mining Co., at Lead, South Dakota.

M. J. HENEY, of Seattle, the railroad builder of Alaska, is at the St. Francis hotel.

CHARLES G. YALE has ceased to be statistician to the California Mining Bureau.

GEORGE B. PUTNAM has returned to Pilares de Nacozari, Sonora, Mexico, from Denver.

CHARLES C. GATES is to be superintendent of the Giroux mines at Ely, Nevada.

J. B. HIGGINS, lately on the Simmer & Jack mine, at Johannesburg, is at Reno, Nevada.

H. DEC. RICHARDS has returned to San Francisco from Orleans Bar, in Siskiyou county.

ROBERT H. RICHARDS is paying a professional visit to Great Falls and Anaconda, Montana.

CURTIS H. LINDLEY has changed his office from the St. Mungo to the Mills Bdg., San Francisco.

WAGER BRADFORD, lately at Johannesburg, is here for a few days, preparatory to returning to South Africa.

T. L. GREENOUGH, on his return from Arizona, was in San Francisco, on his way to the west coast of Mexico.

HOWARD A. POILLON, recently superintendent of the McCracken Hill mines, in Arizona, is here for a few days.

J. C. NIVEN and LYTTLETON PRICE have opened an office as mining engineers in the Dooly Bdg., Salt Lake City.

W. ROWLAND COX has resigned as assistant general superintendent for the American Smelters Securities Co., in charge of mines in Mexico, in order to engage in private work.

S. H. BALL is in the Congo Free State. A party under his command had a big fight with natives lately on the concession near the Kasai river; more than a hundred of the attacking party were killed.

WILLARD S. MORSE, member of the executive committee of the American Smelting & Refining Co., has established headquarters at Salt Lake City, and is to have general supervision over all of the American smelting enterprises in Utah, Montana, and Nevada.

Obituary.

HENRY BURROW VERCOE died on December 17, 1907, at St. Leonards-on-Sea, Sussex, England, after a long and serious illness. He was the eldest son of the late Captain John Vercoe, of Bodmin, Cornwall, a well known mining engineer in the early days. For many years Mr. Vercoe was actively engaged in mining in various parts of the United Kingdom, and for twelve years prior to his retirement he had been heavily interested in gold and copper properties in California.

Commercial Paragraphs.

C. O. BARTLETT & SNOW Co., of Cleveland, Ohio, report increased inquiries and sales for their dryers and elevating machinery.

THE ALLIS-CHALMERS Co.'s Bulletin No. 2027, entitled 'The Hydro-electric Plant at Trinity River, California,' contains information on an interesting power transmission system. This plant is one of those which has been constructed with an eye to the future rather than the present needs of the communities which it serves. It is situated in the central part of Trinity county, California, two miles below the town of Junction City, where Canyon creek, from which the water used for power is obtained, flows into the Trinity river, having a drainage area of 52 square miles. The dam, which is small, serves merely for diverting the water. Alternating sections of ditch and open flumes, with a total length of 5250 ft. and a tunnel 1821 ft. long are comprised in the system. An effective head of 600 ft., or working pressure of 260 lb. per sq. in., is obtained from two penstocks, each 1165 ft. long. This power-house is equipped with Allis-Chalmers electrical machinery, consisting of two three-phase, 25 cycle generators, each 750 kw., 500 r.p.m., 2200 v., seven step-up transformers, and auxiliary apparatus. The description of the entire plant is quite complete and will be found of interest by engineers and students.

General Mining News.

ALASKA.

Many prospectors have outfitted to prospect next season for quartz veins in the Knik Arm region; heretofore this district has been prospected chiefly for placer mines.——The Ready Bullion Copper Co. has moved an air-compressor to its mine at Lynx creek and intends to drive an adit.——Last season Hatcher & Carne found several quartz veins at Willow Creek, about 25 miles north of Knik Arm. Some of the ore is said to carry $200 to $968 gold per ton; another vein that they intend to develop this year is said to carry $5 gold per ton.——Bartholf Bros. have found a vein of gold ore and expect to erect a small stamp-mill next summer.——It is said that James Girdwood secured 200 lb. gold at his placer mines on Crow creek near the Alaska Central railroad.——Late arrivals from the Cache Creek district, at the base of Mt. McKinley, report that a very rich pay-streak has been found on the south bench.——Fifty tons of Matanuska coal will be sledded to Knik Arm during the winter, for the purpose of a test by the Government.——Reports from Eagle River indicate that a promising lode has been found there. It has been developed by surface cuts at six places, all of which are said to have good ore.——Tailing dumped into the sea by the Topkok Ditch Co. has caused the water to recede so far that by sinking shafts from the top of the tailing pile it has been possible to get pay-gravel that formerly was beneath the sea. William O'Brien has found good gravel in this manner; Louis Lane and Ernie Blanck have begun drilling at the same place.——Near Nome the known extent of the third beach line has been increased one-half mile by its discovery by W. West on his claim west of the Humboldt claim. This is considered an important discovery.——It is reported that N. Butler and J. Plein have reached better gravel at Dry creek than that formerly worked on the ground.——Carliss Bros. are drilling for coal near Sinook river on Seward peninsula.——At the Slisco antimony mine at Manilla creek, 25 miles from Nome, an adit has been driven 300 ft. into the mountain; recently the owners found a gold-bearing vein that carries, it is said, $25 to $30 per ton, in addition to the antimony.——Joe Kennedy has found a copper-bearing lode on Brooks mountain.——The second beach line has been found on the California group of claims, 3½ miles west of Nome.——Peter Esch is developing a large body of iron ore near Sinook river.

ARIZONA.

COCHISE COUNTY.

Timbers are being prepared at the Savage mine for timbering the new shaft.——B. M. Pattison has resigned as superintendent for the Denn-Arizona and Shattuck-Arizona copper companies; S. A. Parnell will take his place.——It is stated that an English syndicate is negotiating with the Arizona-Apache company for the purchase of the Foran group of claims in the Catalina district.—At the Mayflower mine in Johnson district an inclined shaft 65 ft. deep has been sunk; it is announced that the company has decided to sink a vertical shaft on the hanging-wall side of the vein, and that a contract will soon be let for the first 300 ft. of this shaft. J. D. Sullivan of San Francisco is president of the company.

GILA COUNTY.

The Arizona Commercial Co. has announced that it will soon resume shipping ore from the Black Hawk mine to the Old Dominion and Shannon smelters, and probably to the smelters at Douglas. Recent developments on the 500-ft. level of the mine indicate continuance of the vein to considerable depth. A general sample of ore exposed in a winze east of the shaft carried 10% copper, 4 oz. silver, and 0.02 oz. gold per ton. The new three-compartment shaft on the Eureka claim will be sunk to a depth of 430 ft.

GRAHAM COUNTY.

The cost of producing copper at the Shannon property, it is stated, has been reduced over two cents per pound in the last two months, through the installation of new machinery and other innovations. N. L. Amster is president of the Shannon company.

MARICOPA COUNTY.

Part of the machinery for a 150-ton mill has been received at the Fortuna mine; it is hoped to have the plant completed in three or four months. F. W. Bithell is manager.

MOHAVE COUNTY.

A Los Angeles company is working the Jim Blaine mine, near White Hills; a good strike of silver ore was made there recently.——At the Victor mine the ore has been given a thorough test in the new mill, and it is thought advisable to start the tube-mill and cyanide plant.——J. E. Rose is preparing to mine the bars and bank of the Colorado river at a point north of White Hills.——At the Expansion mine in the Union Pass district a large force of men is working. A mill is to be erected soon.——A shaft is being sunk at the Billy Bryan mine.——Foster & Murphy have a large force of men at the Atlantic and Pacific mines near Thumb Butte, in the Union Pass district.

PINAL COUNTY.

The Keystone drills at the Ray copper mine have, it is said, brought to light some fine ore. Seven carloads of coal have been received by the company to keep up the work.

SANTA CRUZ COUNTY.

A Tucson publication announces that there is no truth in the statement recently made in local papers that the Mansfield company is sinking a shaft to the 550-ft. level in the Sweet mine and is mining ore on the 250-ft. level. It appears that at the time no work was being done at the property unless by the watchman in charge.

YAVAPAI COUNTY.

It is said that the owners of the Octave mine are planning to increase the size of the mill to 120 stamps, and that there is sufficient ore blocked out in the mine to supply such a plant for four years. On the 1600-ft. level an orebody 4 ft. wide has been found in a cross vein; it is quartz carrying much sulphide and streaked with gold. At the 1100-ft. level of the Joker mine there has been found an orebody that averages $33 gold per ton. The 40-stamp mill and 250-ton cyanide plant are running day and night. As the result of two weeks' run, the mill has yielded 1213 oz. of bullion.——The Black Mountain Copper Co. has purchased a hoisting plant and air-compressor; it is planning to sink the 135-ft. shaft several hundred feet deeper. The vein carries gold and copper.——At the Snoozer mine the burning of 90 cords of wood nearly set fire to the buildings.

The Interior Mining & Trust Co. has between 50 and 60 men employed at its property in the Black Rock district; the 40-stamp mill is producing $10,000 worth of bullion weekly.——At the Unida mine a large orebody carrying gold and copper has been found at a depth of 300 ft. in the new perpendicular working shaft; George Margaretis is general manager.——The Haynes Copper Co. has received five carloads of lumber for the construction of a power-house and gallows frame.——At the Binghamton mine at Copper Mountain I. T. Stoddard has been directing the laying out of a site for a 500-ton smelting plant and the building of a new road from Humboldt to the new townsite of Stoddard.——Some high-grade ore is being taken out of the Cardinal mine; it carries gold, silver, and lead.

YUMA COUNTY.

Geo. W. Norton and the Mathis brothers, it is reported, have made a rich strike about three miles east of Mohawk station. In sinking a 10-ft. shaft for assessment work they secured five tons of ore which, it is said, carries between 100 and 200 oz. silver per ton. A road is now being constructed from the railroad to the property, so that ore may be shipped to a smelter.

CALIFORNIA.

AMADOR COUNTY.

The mill at the Defender mine, about 12 miles east of Jackson, is crushing ore which carries about $10 per ton, and the tailing is being saved for further treatment. The Defender and Tom & Dick mines have come into the possession of the Amador Gold M. & M. Co., which is largely controlled in Boston; arrangements are being made for vigorons development. Large bodies of pyrite-bearing ore below the water level carry sufficient gold and silver to make shipment to smelters profitable.

BUTTE COUNTY.

Work will be commenced soon in building a road to the diamond mine, and when completed the mine will be prospected. The owners propose installing a Keystone drilling plant to determine the extent of the supposed diamond-bearing pipe.——The Steifer Mining Co.'s mine near Magalia is filled with water, and operations have been stopped in the mine until the company can complete a power-plant to pump the water from the mine. P. B. Steifer is superintendent.

CALAVERAS COUNTY.

The employees at the Melones mine, about 65 men, a large majority of whom are non-English speaking aliens, went on a strike Dec. 10 for a nine-hour work day.——It is reported that a dredge will be constructed on the Calaveras river at the mouth of Chili gulch.

INYO COUNTY.

(Special Correspondence).—J. V. McConnell is developing his group of six claims, 18 miles easterly from Big Pine; there are several shafts and an adit 60 ft. long. The lode is 2 to 4½ ft. wide and is exposed at intervals for the length of six claims; it is at a contact between porphyry and granite. The ore from all the openings varies between 5 and 30% lead and $66.50 and $148 gold and silver per ton.——Colorado parties are pushing development work in a very systematic manner at Chrysopolis. ——R. H. Blake is developing his silver-lead mine near the Montazuma mine; the lode is fonnd larger as work progresses.——Joe Wright, in doing his assessment work on his silver-lead property, has found the silver increasing as depth is attained.——Systematic work will be commenced in the spring at the Priscilla Hill gold mine.—— J. W. Tracy intends to erect a 10-stamp mill and concentrators at his mine on the west side of Gold mountain; the mine is developed by a 285-ft. and a 275-ft. shaft connected by a drift 280 ft. long. The ore in the bottom of the shafts is 6 ft. wide and carries $20 gold and silver per ton. This property produced much high-grade silver ore in the early days.——A number of prospectors left recently for Deep Spring valley and most of them are reporting good finds. Johnson & Epperly have an 8-ft. lode with a 10-in. streak of high-grade gold ore.

Big Pine, Jan. 18.

MODOC COUNTY.

A nugget of gold worth $40 has been exhibited in Alturas by a miner from the Mountain Sheep group of claims; there is 5 ft. depth of snow at the property now.

NEVADA COUNTY.

The vein being developed in driving the lower adit of the Ancho mine is proving wider than where first opened; the 10-stamp mill is running regularly.——At the Niagara mine near Deer creek, five stamps are crushing ore from the shaft; this shaft is now 325 feet deep.——At the Dewey mine Matt and Dave Waite have been taking ont ore that contains $16 gold per ton; the vein is 10 to 12 in. wide.—— Prospectors recently located some promising quartz veins in the French Corral district and will proceed with their development. Another prospector exhibits a piece of quartz float that is very rich in gold.

PLACER COUNTY.

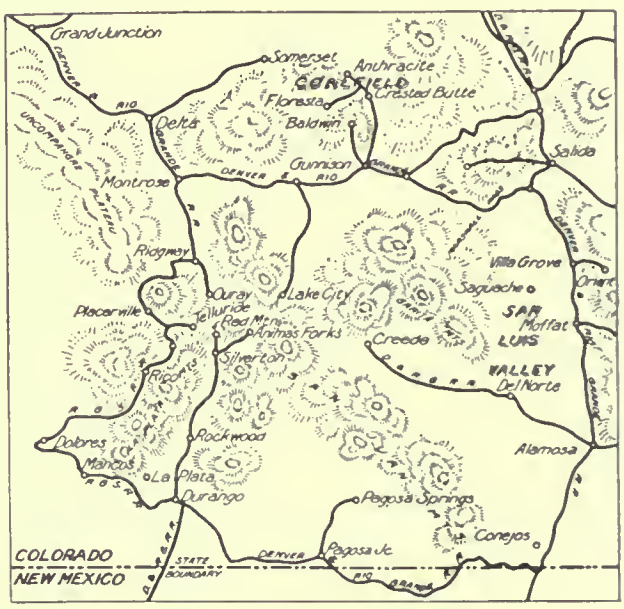
More machinery has been installed at the Dairy Farm mine.——The dredge at Cash Rock is to be in working order by March 1.——Forty men are working at the Slope mine near Forest Hill.——J. B. Patterson has started a new adit at his mine at Boulder Ridge near Penryn.—— At the Herman mine 20 men will be employed during the winter to finish the upraise and stope ore; the 10-stamp mill is running regularly.——At the Bellevue mine driving has begun on the 400-ft. level.——Preparations have been made for sinking a shaft at the Hathaway mine.——At the Orpheum mine the adit has been cleaned and retimbered.

SAN BERNARDINO COUNTY.

The Orange Blossom Mining Co. expects to install a stamp-mill at its property near Bagdad.——C. Ferguson has bought eight mining claims 3½ miles west of Kiinefelter station, and he proposes to commence work on them at once.——B. A. Jennings on Jan. 19 brought to Hart a sack of rich ore from the new strike at the Big Chief mine; every piece fairly glistened with free gold. Seventeen lessees are working on adjacent properties. A water-line is being laid from Malapai springs, four miles distant; telephone wires connecting with the Western Union wires at Barnwell, have been strung.

SHASTA COUNTY.

It is reported that on the 1100-ft. level of the Midas mine the vein has been uncovered for a distance of 200 ft. and that it is 18 in. wide. Sinking to the 1200 ft. level is now in progress.



Map of Southwestern Colorado.

SIERRA COUNTY.

The Sierra Buttes mine and mill have been closed by a strike of the miners, who demand recognition of their union. E. J. Olsen has a lease on the mine and will proceed to work it if the miners agree to accept 25c. per day less until May 1.——The Dead River Mining Co. has decided to resume development at the Wyoming mine in the Alleghany district; the lode is the one that created local excitement in November, as it was discovered in driving an adit to develop the Deep Blue gravel mine at Smith's Flat. S. M. Weiland is superintendent.

TRINITY COUNTY.

It is announced that work at the Bully Choop mine will probably be resumed as early in the spring as the melting of the snow will permit; dissention among the stockholders new perpendicular working shaft; George Margaretis is

TUOLUMNE COUNTY.

While no mill is dropping its stamps at Stent, 16 men are working at the Jumper mine, eight at the Santa Ysabel and six at the Mendonca mine.——At the App mine 140 men are employed.——Experts have estimated that the water in the Dutch mine is 850 ft. deep.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Creole and Argentine properties on Leavenworth mountain have been taken under bond and lease by Wm. Gibson, one of the pioneer operators. Mr. Gibson has started a new adit to cut under the old workings at a depth of 100 ft. In the breast there is showing a 2-in. streak of high-grade silver-lead ore that carries 149 oz. silver per ton.——Heavy shipments are being made from the Cram vein, intersected through the Doric adit, 2400 ft. from the portal. The ore is of a smelting grade and the first-class mills $134 per ton in gold, silver, and copper. Stoping is in progress and a streak of ore is being followed that measures from 18 in. to 3 ft. wide. The ground is being operated under lease by Gileen & Ecklund.——A rich strike has been made at the Hansbrough mine, Columbia mountain. In sinking prospect holes for the proving up of the ground a 6-in. streak of 400 oz. silver ore has been exposed. The ore carries considerable gray copper and glance. The adit is to be extended for the securing of additional depth, and the objective should be reached within 100 ft.——Work will be resumed in a few days on the Morning Glory adit on Saxon mountain. During the past several weeks a force of men has been engaged in cleaning out the workings and reducing the grade of the adit. It is understood that a compressor plant is to be installed. J. F. Puchert of Idaho Springs is superintendent.——The Linn Con. M. & M. Co. is employing a force of men in the construction of its new 50-ton mill. The building has been enclosed for some time, and a portion of the machinery has arrived. The balance has been shipped and should be here shortly. An aerial tramway is being constructed from the sixth level of the Mineral Chief workings, the terminus of which is at the mill bins. This tram will be 3000 ft. long. Frank Graham is in charge of operations.——The Raymond adit on Griffith mountain is being driven steadily forward, and according to surveys another vein should be intersected within the next few feet. Joseph Raymond of Georgetown is directing the work.——The Lincoln adit on Lincoln mountain, which was started to cut the Virginia City shaft workings at the 500-ft. station, is being advanced one to two feet per day. Within 90 days the objective will be reached, at which time the mine will be drained of its large bodies of water.——Enlarged operations have been put under way upon the Smuggler on Brown mountain. The third and fourth levels are being extended to the west and streaks of ore are being followed which are from 8 to 18 in. wide. A number of lessees are at work and steady shipments are being maintained. G. A. Huffman is manager of the property.——Louis Just, leasing on the Frostberg, is carrying a stope on a streak of $80 ore that is 18 in. wide.——At the Seven-Thirty mine Joseph Ebner is employing a force of men in steping upon an 18-in. streak of 240-oz. silver ore. Shipments are being made weekly. ——The Star property situated up Geneva gulch, is making a fine showing. Drifting is in progress upon a 6-in. streak of smelting ore that carries 140 oz. silver and 0.5 oz. gold per ton. Another adit has just been started for the gaining of greater depth. A force of men is now being employed in catching up a number of caves and in cleaning out the workings. John O'Dea is in charge of the work.——Steady shipments are being made from the Poorman mine in the Freeland district. This property is being operated by McKenzie Bros. and returns on the last shipment of 502 oz. silver per ton were received in settlement. Steping is in progress upon a 12-in. streak of mineral.—— The Rough and Ready adit in the same district, is being driven rapidly; it is being run on the vein, and in the breast there is exposed a 3-ft. body of mineralized quartz. ——A vigorous campaign of development is being waged on the holdings of the Atlantic M. & M. Co., situated in the Atlantic district. An adit tunnel has been started which will intersect the veins at great depth. A 6-in. streak of lead ore is showing which carries 52 oz. silver per ton and 55% lead.——The Tam O'Shanter group is being developed in a systematic manner. The adit, in 300 ft., is being advanced and another vein will be reached in another 30 ft.——'Bill' Young, the father of the district, is busily engaged in breaking ore on the lower level of the Smuggler. The ore carries $200 per ton in gold and silver. ——The Tyler adit has been advanced 300 ft. The last vein intersected shows a streak of heavy lead ore 8 in. wide. Drifting is now in progress for the proving up of the ground.

Georgetown, Jan. 18.

DOLORES COUNTY.

(Special Correspondence).—The United Rico Mines Co. held their annual meeting at Denver, on Jan. 14, and elected the following directors: David H. Moffatt, A. B. Roeder, Samuel Newhouse, Leopold Zimmermann, M. H. Hauser, Harry P. Scott, John E. Searles, Maurice P. Blumenthal, and Carl M. Owen. Resolutions were adopted commending the consulting engineer, H. A. Shipman, and the assistant general manager, A. Sheard, for the energy and fidelity which they had devoted to the interests of the company. The president's report and treasurer's report were presented, and they showed that the company was in a most satisfactory condition. In due course a financial statement will be sent to the stockholders. The president's report called attention to the fact that the showing from the first month's operations of the Pro Patria mill was excellent, and that shipments of both crude ore and concentrate had begun. Each week the company issues a statement in the local paper giving an account of progress.

Rico, Jan. 15.

IDAHO.

IDAHO COUNTY.

Development work at the Snowstorm mine near Red river was resumed early in the month; the intention of the management is to sink a winze near the face of the main adit.——The Dixie Royal Mining Co. is commencing operations on its group of placer and quartz claims, three miles below the town of Crooked Creek. A sawmill is being shipped to the property; lumber will be sawed this winter for the erection of a large mill in the spring. The ore consists of a porphyry dike 100 ft. wide that is said to carry $3.50 gold per ton; along one wall of the dike there is a vein 18 in. wide that is said to assay $100 gold per ton, while on the other side of the dike a quartz vein averaging 6 ft. wide is said to carry $35 gold per ton.——Scores of prospectors, it is reported, are hastening to a new camp near the head of the Middle Fork of the Clearwater river; they are attracted by a statement that B. C. Sweatt has there found a vein 12 ft. wide that carries $34 gold per ton.——The prospect of the building during this year of a large power plant, near the mining district along the Ten Mile creek between Orogrande and Buffalo Hump, has stimulated renewed activity there.

NEVADA.

ESMERALDA COUNTY.

The Nevada Legislature on Jan. 16 passed a resolution asking that the Federal troops be permitted to remain in Goldfield until the organization of a State constabulary or other police force sufficient to maintain law and order and suppress any domestic violence that may occur. President Roosevelt replied the following day that he will accede to the request, assuming that there will be all possible expedition in providing this police force. The charter of the Nevada Miners' Union, Incorporated, was filed with the County Clerk on Jan. 18. This is the union that is intended to displace the Western Federation in the Goldfield district, and has the moral support of the operators' association. None but American citizens are eligible. A portion of section three of the charter defines the purposes of the union as follows: "To secure the best wages possible for its members. To regulate the scale of wages between its members as well as between its members and other persons and corporations, and to make all necessary contracts to execute and carry out the same. And, as directed by its by-laws, to visit and comfort the sick, bury the dead, and care for the widows and orphans. This

corporation is not organized for profit and shall have no capital stock. A candidate for membership shall be a citizen of the United States or shall have declared his intention to become such."

The output of the Goldfield mines is very limited under present conditions; most of the working mines are simply developing their ore reserves. The Western Ore Purchasing Co. is receiving small lots of ore from the Florence Annex mine and from the Mohawk-Combination dump. The Combination mill is running at full capacity, treating 80 tons of ore per day, which is all taken from the Combination mine.——Within 60 days the Nevada-California Power Co. will have completed its parallel power-line from Bishop to Goldfield; 40 men are at work on the line.——The Florence-Gem lease has developed a 4-ft. vein of shipping ore which carries a 6-in. streak of ore that is plastered over with gold.——The Nancy Donaldson mine in the Red Mountain district, which produced high-grade ore two years ago, is to be developed on an elaborate scale.——The Diamondfield Red Mountain Mining Co. is sinking a shaft on its property; the ore developed by it carries from a few dollars to $664 per ton.——At the Idol's Eye claim in the heart of Goldfield a well-defined body of ore has been found.——A new district is that of Marlview, six miles from Thorne.——The Treasure Hill Mining Co. has 75 tons of high-grade ore ready for shipment from its mine near Silver Peak.——About 40 tons of ore from the Valcalde mine are being crushed daily; it yields $17 per ton. C. L. Knight is superintendent.——The Original Rawhide Mining Co. has about 50 tons of high-grade ore ready for shipment; the shaft is now 100 ft. deep.

LINCOLN COUNTY.

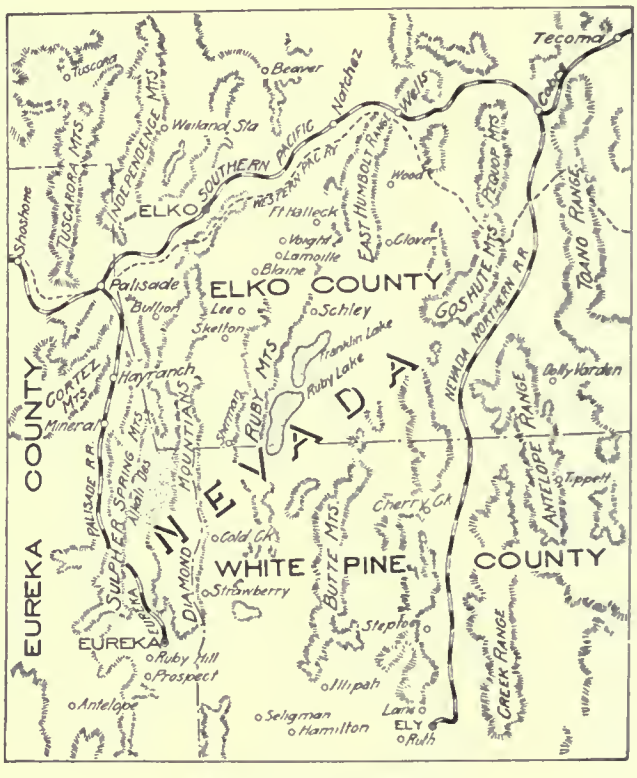
The New York-Searchlight Mines Co. is advertising for bids on 300 ft. of cross-cutting in its Waterspout mine, near Searchlight. The company will do the hoisting and to that end will install a 15-hp. hoist.——F. C. Perew has gone to Denver, Colo., to purchase a large mill for the Blossom mine in the northern part of the Searchlight district.——At the Colorado mine two large electric pumps, a 25-hp. hoist and a 50-hp. engine have been installed; vigorous development of the mine is shortly to begin.——The Nevada-Eldorado Mines Co., operating at Eldorado canyon, has developed down to a depth of 375 ft. a strong orebody of excellent milling grade.——Steady development has commenced at the Silver Dollar mine near Nob Hill; the mine has recently yielded some ore carrying 30% copper and much silver.——A 40-hp. hoist has been ordered for the Lodi shaft of the Philadelphia-Searchlight mine; a large body of low-grade ore is being systematically developed.——At the Blue Point mine there has been found an orebody 4 ft. wide which assays 2 to 20% copper; more energetic development is being planned.——A large body of ore that pans well in gold was found in doing the assessment work on the Florence group of claims. The ore is a heavy red-stained quartz; it is wider than the shaft at a depth of 30 ft.——A. J. Weeks and Walter Maxwell are driving an adit at the Alice mine to develop a lode that is 12 ft. wide and said to assay $5 per ton.——Smith & Bowman have installed a small hoist at the Shoshone mine, near Summit Springs, and have arranged to have ore milled by the New Era Co.; the ore they are now taking out is expected to yield between $12 and $15 per ton.——A carload of ore recently shipped by the Boston-Pioche Mining Co. from the Yuba East claim is estimated to contain a value of $110 per ton; shipping upon an extensive scale will be postponed until the shaft now being sunk is connected with the ore-shoot.

LYON COUNTY.

The 5-stamp mill at the Wheeler mine, which has heretofore been running for one shift per day only, is to be operated continuously hereafter; large bodies of ore are blocked out in the mine.——Two shafts on the property of the Yerington Copper Mountain Co. are said to be in good ore; the Lydia shaft has an 18-in. vein extending from the top to the bottom.——At the Mason Valley mine an adit is being driven to cut the lode at considerable depth. It is intended to resume operations on a large scale at an early date; the new power plant is completed.——The Wilson Gold Mines Co. has found a new body of rich ore in its mine in the Mountain View district; a contract has been let for driving a 100-ft. adit and at the same time the main shaft will be continued down.——At the Black Horse mine near Pine Grove an ore-shoot containing gold visible to the unaided eye has been found.——Wm. Richards and others have found on the Red Bird claim two well-defined veins that assay well in gold.——The McConnell shaft is still being sunk and is in the garnet-bearing limestone capping of the orebody; six men are working in it.——On the 550-ft. level of the Ludwig mine an orebody averaging 12% copper has been found.

NYE COUNTY.

The ore shipments over the Tonopah & Goldfield railroad for the week ending Jan. 16, as reported by the Western Ore Purchasing Co., aggregated 366 tons, divided as follows: Jim Butler, 175 tons; Tonopah Extension, 88; Midway, 103. The Tonopah Co. sent 2850 tons, the Belmont company 300 tons and the Montana-Tonopah 1100 tons to the mills, making the total shipments for the week 4616. The total output of the Tonopah mines was 4616 tons, of



Map of Eastern Nevada.

an estimated value (the shipping ore being valued at $50 per ton and the milling ore at $20 per ton) of $103,000.——On the lower levels of the Midway and Montana-Tonopah mines, work is being done under the direction of Mark B. Kerr to study the extent of the dacite intrusion that has given so much trouble in Tonopah mines. In the Midway mine the edge of one of the dacite tongues is being followed below the 800-ft. level; at the 900 ft. level the adjoining quartz body will be prospected, but sinking will be continued.——At the Tonopah Extension mine ore is being extracted on all levels above the 600 ft.; the north cross-cut on the 1050-ft. level is progressing satisfactorily.——Work is being pushed on all levels in the Jim Butler mine; the mill-dump is growing rapidly and the bins are kept full of high-grade shipping ore.——At the West End Consolidated mine the customary quantities of high-grade ore are being extracted; exploration is proceeding on the western extension of the 400-ft. level.—The clean-up of the Sunnyside mill in the Round Mountain district for December was $20,330.20; James McDonald is superintendent.

WHITE PINE COUNTY.

On the evening of Jan. 18, A. D. Bailey, Fred McDonald, and Pete Brown, the three miners who had been impris-

oned in the Alpha shaft of the Giroux mines for 45 days, were rescued; the entombed men had been working several hours in digging their way to freedom.——E. A. Harrington is developing the Columbia gold mine which is owned by W. D. Campbell; a small body of good milling ore has been found.——Lessees in the Black Horse district are sacking ore for shipment; some of this ore carries $800 to $900 per ton.——On Jan. 10 tracklayers reached the Veteran mine with the last rail of the ore line.

The management of the reduction plant which is being built by the Nevada Consolidated and Cumberland Ely companies has announced that work on the plant at McGill will proceed rapidly during this year; at least half of the great smelter and concentrator will be completed as soon as possible. Two units of the concentrating plant will be put into commission early, instead of one as previously planned.

NEW MEXICO.

SOCORRO COUNTY.

The developments in the Magdalena district during 1907 were of more importance than in any previous year. The Graphic company has exposed ore on the seventh, eighth, and ninth levels; the ore-shoot is about 400 ft. long and on the ninth level is 105 ft. wide. The ore is principally zinc sulphide, occasionally merging into zinc-lead sulphides, which require mechanical separation. Some of the ore carries 40% zinc, but most of it is low-grade, requiring concentration. The company has been experimenting with several milling processes and it is generally understood that it will soon install a concentrating plant.——At the Tri-Bullion mine a 250-ton concentrating plant has been installed; a large tonnage of both zinc sulphide and zinc carbonate ore has been developed in the Kelly mine.——The Mine Development Co. commenced shipping oxidized lead ore in September, but suspended about Dec. 1. It is now pushing the development of several mines along the Tip Top adit. The workings are all being driven in oxidized lead ore which contains about $1 gold per ton.——William Martin has been shipping lead carbonate ore that carried 8 oz. gold per ton.

WASHINGTON.

STEVENS COUNTY.

(Special Correspondence).—A new and important strike has been made in the First Thought mine, on the 200-ft. level.——Fresh capital has been obtained for development of the Chief & Butte mine and the working force will be increased. The products are bornite and azurite, and the value of the ore in copper is better than ordinarily found near the surface. There is considerable ore in reserve.——A new adit has been started on the Trophy mine.——The Katie mine on Toulon mountain is producing good copper-gold ore.——Work has been resumed at the Sure Thing mine, near Orient.——In Deer Trail camp considerable activity prevails; the Rosalie company is getting out tungsten ore of good quality.——The Germania Mining Co. is operating the Seal and Queen claims under bond and is ready to ship a carload of ore which carries 170 oz. silver per ton. The company is employing 23 men on these claims and getting considerable development work done.——The old Deer Trail mine is being operated under lease; a carload of ore was recently shipped.——The Togo mine is producing copper ore in small quantities.——In Chewelah district a 3-ft. vein of copper carbonate has been cut in the lower workings of the Copper Jack mine. In the Jay Gould mine a drift on the 200-ft. level has been driven 48 ft. in galena and copper concentrating ore; a cross-cut has been started on the lower level.

At the United Copper mine, on the 400-ft. level the vein has been followed over 200 ft. There are 150 tons of ore on the dump. A late report stated that 18 in. of gray copper had widened farther on to the full width of the drift, 6 ft.; an assay ran 16.3% copper, 150 oz. silver per ton, and a small value in gold. The working force has been increased from 15 to 30 men, and five more teams have been engaged, to increase the haulage and shipment of ore.

Republic, Jan. 17.

CANADA.

BRITISH COLUMBIA.

The enlargement of the lead plant at Trail now makes it unnecessary to ship any St. Eugene lead concentrate to Europe.——During the past five months the Granby Consolidated M. & S. Co. has added to its smelting plant a new line of coke and ore-bins 800 ft. long, and a new structural dust-chamber. In a short time it will be smelting 3200 tons of ore per day. It has plenty of coke on hand and can get all the men it wants at reasonable wages; unless something unforeseen happens it expects to treat its normal amount of ore every month.——The 200-ton mill at the Blue Bell mine near Nelson is nearly completed; in a short time the company will resume the development of its ore-bodies.——The Elmore Oil Process Co. is erecting a small mill for the reduction of ore near Golden.——At the Little Bertha mine a concentrating plant may be erected; the mine is to be operated to its full capacity.——The Providence Mining Co. is advertising for bids for an issue of $50,000 in bonds.——Hedley Miners' Union No. 161, it is understood, has accepted the lower wage scale which went into effect on Jan. 1, being that now in force in Phoenix, with some exceptions.——A 4000-ft. adit for the Krao mine at Ainsworth is proposed.——Sand from near Quesnel, tested in New York, gave 3 oz. platinum per ton; its working will be profitable if it can be concentrated. Work at the Slocan Bell mine has opened some small ore-shoots.——The shaft at the Orphan Boy mine near Kamloops is being deepened to 100 ft.——Delay in the arrival of tramway fixtures has prevented ore shipments from the Eureka mine in Star gulch.——At the Kokomo mine an orebody 6 in. wide has been found.

ONTARIO.

During 1907 the mines of the Cobalt district shipped 14,040 tons of ore, valued at between $10,000,000 and $12,000,000. The following are the shipments in pounds from the various mines: Buffalo, 2,208,820; City of Cobalt, 101,280; Conlagas, 4,798,710; Cobalt Central, 101,360; Colonial, 74,250; Drummond, 108,920; Foster, 611,806; Green-Meehan, 196,780; Hudson Bay, 243,170; Imperial Cobalt, 37,530; Kerr Lake, 644,800; King Edward, 62,250; La Rose, 5,706,875; McKinley-Darragh, 1,407,935; Nipissing, 4,788,249; Nova Scotia, 493,000; O'Brien, 2,666,360; Red Rock, 91,443; Right-of-Way, 258,220; Silver Leaf, 93,618; Silver Queen, 957,157; Tretheway, 1,710,438; Townsite, 234,278; Temiskaming, 430,611; University, 61,388. Total, 28,081,010 pounds.

YUKON.

News of three rich strikes in the Peel River and Sulphur Dome districts has reached Dawson. Indians have brought to Dawson from Peel river samples of decomposed rock abounding with gold.——At Haggard creek in the Sulphur Dome district placer ground yielding from 60c. to over $3 coarse gold per pan has been found. The alluvium along the creek has all been staked and will be thoroughly explored before spring.——It is also reported that rich placer ground has been found near the head of the White river, where many Yukon prospectors are spending the winter.

A rush of prospectors has followed the discovery of rich gravel on Black Hills creek, a branch of Stewart river; the alluvium has been staked from Sixty above to the mouth of the stream, 33 miles, the last claim being No. 164. Stampeders are staking the tributaries. The valley of Black Hills creek is not proved ground, but rich gravel has been found on No. 112 below, No. 7 below, Discovery, No. 11 above, No. 23 above, and a few other claims; over 100 men are working enthusiastically in the valley.——On the left fork of Little Branch creek near Dawson, 5c. to $1.40 per panful of gravel have been secured. A strike has been made by Tom Babcock, Al Lobley, and Nathaniel Mercer on No. 10 claim; the alluvium has been tested by a cross-cut 22 ft. long and rich gravel is present throughout it.

Engineers and Capitalization of Mines.—A Suggestion to the Institution.—Tanganyika Concessions.—The Frecheville Report.—Australian Smelting Corporation.—De Beers and the Diamond Trade.

In your issue of November 2, Mr. T. H. Leggett deals with a subject that is of considerable interest to English mining engineers. His letter was written with the purpose of showing that the engineers on the Rand have no voice in the capitalization of the mining companies, and he mentions that as a rule the engineer is never asked by London promoters for his opinion as to what capitalization a particular mine will stand. It is this point that I wish to enlarge upon. In London, mining engineers may be divided into two groups. In the first group there are such firms as John Taylor & Sons and Bewick, Moreing & Co., who not only send their engineers to inspect properties, but also form companies and raise capital to work them. The other, and larger, group consists of those who are purely engineers, who are deputed by financial houses either to examine mines or to manage them. Sometimes these engineers give their services entirely to one financial group, as is the case with the engineers employed by the South African houses, and in other cases the engineers enjoy an independent consulting practice.

The grievance, sometimes expressed, but more often not, of this second group of engineers is that, as Mr. Leggett says, they are never consulted about the capitalization of the companies formed to acquire particular mines. The consequence is that many a time a mining engineer who has reported favorably on a mine or who has been manager of a mine, finds that his report or work is used against him when the mine has proved unequal to the task of recouping shareholders for the capital sunk in the company. He naturally knows that his experience of mining has not been fully used for the benefit of the shareholders, but as yet he has no redress. The financiers and the Stock Exchange are too strong for him. Unless he deports himself as the 'City' requires, he is of no use. Pessimistically speaking, he is a mere hewer of wood and drawer of water. As a rule he says to himself: "I have come to the City to do business and I must make up my mind to pocket my own feelings and do as the City does." It is not only that the nominal capital of the company is placed at far too high a figure, but that the underwriters and Stock Exchange further inflate the price of the shares. The directors of such companies generally plead ignorance of the reason why such inflation has taken place and of the identity of the inflaters, but their protestations are usually insincere.

How engineers are to combat this incubus of overcapitalization and inflation is not quite clear, as the financiers occupy the citadel so strongly. But it is obvious that until the engineers are allowed to give their opinion on the subject, mining as directed from the city of London will not be as sound a business as it should be. Eventually I hope that engineers as a body, through the Institution of Mining & Metallurgy, will take some steps, slow but sure, toward making the engineers' opinion on the money value of a mine of greater weight among investors and shareholders. I put forward this suggestion to the Institution in all seriousness, for this, as much as anything, will elevate the profession and increase its dignity and influence.

A week or two ago I sent some information concerning the great copper deposits in northern Rhodesia, owned by the Tanganyika Concessions Limited, and I mentioned that everybody was looking forward to Mr. R. J. Frecheville's report. Your readers will remember that the earliest information about these deposits was received with scepticism on account of the unusually glowing nature of the reports. Subsequent information went far to confirm the first news. Recently Mr. R. J. Frecheville went out for the Consolidated Mines Selection Co., so as to advise his company on the desirability of taking up an interest, and I said that, for myself, I would accept Mr. Frecheville's views as conclusive. It appears, however, that there is very little chance of his report being made public. The position is somewhat humorous. Seeing that he was sent out at considerable expense by the Consolidated Mines Selection Co., his report will not be handed over to anybody else without the payment of a considerable fee. As a matter of fact, the amount asked is £4000. This amount, neither the Tanganyika Concessions, nor the Union Miniere Co. of Brussels, which is working in conjunction with the Tanganyika Concessions, is inclined to give, which is a pity. In the meantime it is interesting to note that the arrangements for smelting the ore are proceeding apace, and that Mr. Allan Gibb, the metallurgist, speaks very confidently. Mr. Gibb is a Royal School of Mines man and son of the late Thomas Gibb, who was for many years with the Broughton Copper Co. of Lancashire. Until recently Mr. Allan Gibb has been engaged in copper smelting in Queensland.

The troubles of the Australian Smelting Corporation are by no means over. A few weeks ago I gave some information, at the time when the first annual report was issued, and I sketched the history of this undertaking. The directors have issued a circular to the shareholders stating that the negotiations for the sale of new shares have fallen through and that there is no alternative but to reconstruct the company and assess the shareholders. It appears that the immediate reason for this crisis is the opposition on the part of some of the shareholders to the policy of the directors, and that in consequence the calls on £20,000 worth of shares cannot be collected. Legal proceedings are being taken by the board to enforce the payment of these calls, but the action will not come on for yet a while, and in the meantime the funds of the company are exhausted and progress in erecting the smelter at Port Kembla is interrupted. In order to raise further funds, negotiations were opened with certain parties in Australia whereby a block of 7% preference shares would be taken up. Unfortunately, however, the price of metals has fallen to such an extent that these people in Australia have changed their minds and withdrawn from the negotiations. It is impossible to create any more debentures, as the legal limit has already been reached. The directors have, therefore, no option but to ask the present shareholders to put up further funds in order to keep the company going. There are 140,000 shares, and a 5s. assessment will bring in £35,000, supposing that everybody takes up his quota. But as there are already some 20,000 recalcitrant shares, and as there is further discontent among shareholders, it is difficult to say how much money will be subscribed. The outcome of these proposals will be awaited with interest.

The London market has been paying a good deal of attention to De Beers and other diamond companies' shares during the last month or two, owing to various happenings. It is customary for the De Beers company to pay an interim dividend on the deferred shares at about this time. It came as a surprise, therefore, to find that no such dividend is to be paid this year. All sorts of rumors have been disseminated in explanation of the

event. Approaching exhaustion, competition of other producers, decrease in the demand, and other reasons are freely mentioned, but nobody outside the control knows the whole truth. The De Beers company makes up accounts yearly to June 30. The last report, for the year 1906-7, showed gross receipts £6,570,000 and dividends £2,550,000, both being an increase over the previous year. The directors state that the production and profits so far during the current financial year (beginning July 1, 1907) show no falling off, but that owing to the slackening of the demand they consider it best to make no disbursement in the way of interim dividend, preferring to keep large sums of money on hand. I believe that the American financial stringency has a good deal to do with this slackening of the sale of diamonds. It is probable, also, that the large output of the Premier mine is affecting the De Beers considerably. It is interesting to note that an agreement has been arrived at between these two companies for controlling the disposal of their products. Nothing is said in the recent reports about the present productiveness or the future prospects of the De Beers mines, but it is well known that the yield per load has been decreasing, and that the output of blue ground has been increased in order to maintain the output. At the present time the intention of the directors is to curtail the production to make it commensurate with the demand. Another worry that the directors have is the increasing pressure of taxation both in Cape Colony and in England. The taxes have been materially increased in Cape Colony and amount to something like £300,000 a year. In England the courts have recently held that the company, though registered in Cape Colony and operating there, is liable for the English income tax of 5% on the whole of its profits; this materially affects the profits.

Johannesburg, Transvaal.

Decline in Share Values. — A Comparison. — The Figures for November.—Better Supply of Kaffir Labor.—Labor Problem not Solved. —A Stope-Drill Competition.

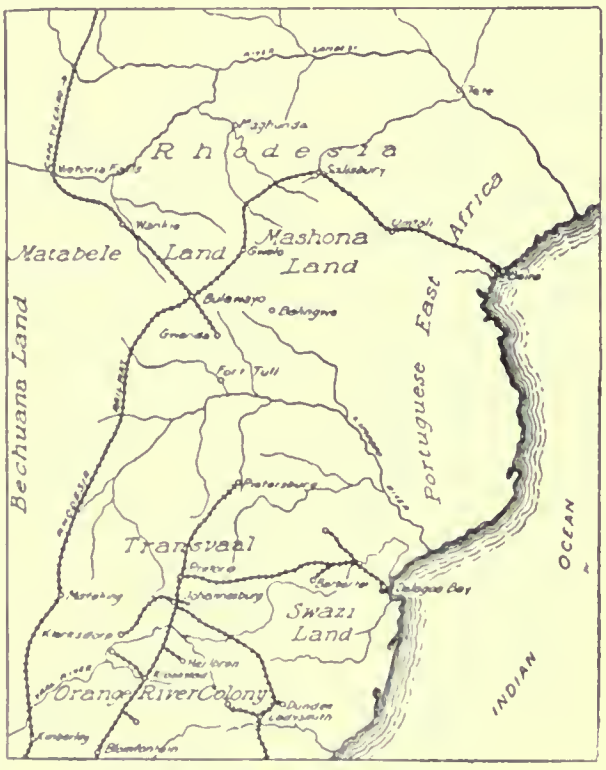
In looking over some old papers the other day, the writer came across a price list of shares of the Rand, dated October 13, 1902. A comparison of the prices prevailing today, with the values in 1902, shows what an awful shrinkage has taken place in the values of Transvaal shares during the past five years. Just after the war optimism ran riot, and it seemed possible to float any piece of land in the Transvaal as a gold mine. A few far-seeing hard-headed men warned the public that prices were entirely too high, and that a collapse was inevitable. But a veritable craze for 'deep levels' was raging, and people seemed to think it would be possible to follow the reef to the centre of the earth and make it pay all the way down.

But the prices of today show what a collapse has taken place. I pick out a few stocks at random, giving their prices five years ago and today:

Mine.	Price Oct. 13, '02. £ s. d.	Price Dec. 12, '07. £ s. d.
Rand Mines	11 9 0	5 4 0
Barnato	3 6 0	1 0 0
Jupiter	3 10 0	0 12 6
Albu	3 6 9	0 19 3
Anglian Mining	1 2 9	0 1 6
Cinderella Deep	3 0 0	1 15 0
French Rand	3 13 6	0 16 0
Randfontein	3 4 9	1 10 3
Simmer East	3 19 0	0 9 6
Robinson Central	4 5 6	5 0 0
Wit Deep	4 1 6	3 10 6

A striking feature about this depreciation is the fact that shares like Rand mines, which were spoken of as safe as the bank of England should have tumbled so disastrously. The 'safe' shares have had the same fate as the highly speculative ones, and in only one case, that of the Robinson Central Deep, is the valuation higher today than in 1902. Jupiters show the awakening of the public as far as the 'deep deeps' are concerned. While the 'deep level' fever was raging, this mine, which strikes the reef at about 4000 ft., was valued by the public at 70s., but in these days of reflection it stands at only 12s. 6d., a figure quite high enough. A few people here and there who have saved something from the wreck, are buying up some of the sounder shares on the Rand, as they declare that at the present prices they can get a good return for the money invested.

The performance of the mines for the month of November is highly creditable. In a month of 30 days the output shows only 3752 oz. less than for October, which had one day more. The total yield was 519,801 oz., valued at £2,335,406. During November three companies produced over 20,000 oz., while there were twenty yielding



Map of the African Goldfields.

10,000 oz. and over. On account of losing a large number of Chinese coolies during November, the Simmer & Jack mine, which generally heads the list, gave way to the Robinson company, which produced 25,300 oz., the output of the Simmer & Jack being 21,210 oz. The third producer was the Robinson Deep, with 20,621 ounces.

As regards native labor, there were 10,990 natives distributed during November, while 7091 departed, showing a net gain of 3899. There are now 107,556 Kaffirs at work on the Rand, probably the highest number on record. During November there were 4610 Chinese laborers lost by repatriation, death, etc., and there are now 37,728 indentured laborers in the Transvaal available for work on the mines. So far the replacement of Chinese by Kaffirs has been most satisfactory and as yet no trouble has been experienced in procuring sufficient labor. Of course Het Volk, the Boer party, is jubilant over this fact, and are never tired of rubbing it in that the importation of coolies was unnecessary. But they are crowing too soon. At present there is one of the worst depressions ever known in South Africa, and the natives are forced by the economic situation to

come to work. If prosperity ever returns, the supply of Kaffirs for the mines will fall off automatically.

The men who see the future clearly, such as mine managers, consulting engineers, and technical newspaper men, realize that the labor problem is by no means solved, but that we shall be "up a tree" if we don't look ahead. For this reason every effort is being made to find out the best small rock-drill to replace hand labor. There are many on the market, and in order to prove which is the best, *South African Mines* has started a competition, which is being patronized by all the small stope-drills on the market. This well known technical journal has shown the most commendable public spirit in this vital question of the finding a suitable power-drill for the small stopes of the Rand, and if it succeeds, the labor problem will be partly solved. It is because of the unsuitable underground conditions that so much hand-labor is necessary on the Rand. The extension of labor-saving devices, with the probable increased use of white labor, might yet solve the difficulties of the mining industry of the Transvaal.

Guanajuato, Mexico.

The Consolidated Co.—Description of the Mill.—Composition of the Ore.—Good Results.—The Mineral Development Co.—A Deep Shaft.—San Matias.—The Pinguico and Peregrina Mines.

The Guanajuato Consolidated Mining & Milling Co., controlled and managed by the MacDonald brothers, is mining and milling 300 tons of ore per 24 hr. A one-mile cross-cut equipped with facilities for electric haulage affords access to the main orebodies. The present active workings are all below the main haulage level, and the electric hoists used in lifting the ore from the lower levels are installed at under-ground stations. At the portal of the main cross-cut are the electrically driven air-compressors, crushing plant, and sorting tables. The ore, after being crushed to 1-in. size, is hauled to the mill in self-dumping cars by electric locomotives, the distance being 2800 ft. The mill has 80 stamps, 1250 lb. each, crushing the ore in cyanide solution, discharging from the mortars through 50-mesh screens. This is followed by cone-sizing, the slime passing to settlers, the heavier material to Wilfley and Standard tables. The table tailing passes to Frue vanners, the tailing from the latter to cone classifiers, in which the sand and slime are separated.

The sand is conveyed to leaching-vats and the slime to pulp-thickening vats. In the latter the slime is thickened to 68% moisture and sent to the leaching-vats where the pulp undergoes agitation for 24 hr. by mechanical agitators and centrifugal pumps, a stronger cyanide solution in the meantime being added. After settling six hours the enriched solution is decanted and passed to clarifying vats, thence to the precipitating room. The same material, from which the solution has been drawn, is again agitated in wash-water and the dissolved metals again drawn off. The company has installed a Ridgway filter-press, which is intended to handle the final slime that now discharges into the creek. This is of Australian design and has been successfully used in Australian mills. The machine is being tried, with the intention of adding others of the same kind if this one proves successful. The sand undergoes four days treatment in one set of vats and is then transferred to other vats in which it receives from eight to nine days additional treatment. The concentrate from the tables and vanners, which is sent to the smelters, carries about 50% iron sulphide and 5% silica. The ores carry about 85% silica, 4 to 5% iron, having a total value of P25 per ton, 10% of which is gold and 90% silver. The extraction is stated as 90% of the silver and 97 to 98% of the gold. By the use of filter-presses it is anticipated that even a higher extraction will be reached, especially as to the silver.

For sand treatment the solution is 0.035% cyanide, this stage terminating with a weak solution containing 0.01% cyanide and a final water-wash. In the slime treatment eight solution washes and two to three water-washes are given, the strength of solution being 1% cyanide. Lime to the amount of 1% is added to the pulp in the batteries and another 1% to the sand when it is transferred from the upper to the lower vats. The same amount of lime is also added to the slime when charging. To the slime is also added 0.15% of lead acetate and to the sand 0.05%. Ten tons of solution is used to one ton of ore; and seven tons of solution to one ton of ore is passed to the precipitating room. The consumption of zinc amounts to 1.37 lb. per ton of ore treated. The consumption of cyanide is 2.86 lb. per ton of ore. Bernard and Joseph MacDonald are concerned in the active management of the property. W. B. Timins is mining engineer and surveyor; Parish MacDonald, mill superintendent; R. Vaughn, superintendent of cyanide plant.

The Mineral Development Co., organized by mining men and engineers of New York, Philadelphia, and elsewhere is sinking a prospecting shaft on the Nueva Luz, adjoining the Valenciana, near Guanajuato. The shaft is three-compartment, 8 by 17 ft., is equipped with a double-drum electric hoist and an Ingersoll-Rand air-compressor. The depth already attained is 1000 ft. and the plan is to sink to a depth of 3000 ft., with the idea of cross-cutting from various stations to the Veta Madre. This company has a concession from the Mexican government whereby it is to receive a subsidy for depth attained below the 500-m. level. H. H. Miller, one of the stockholders, is the company's manager.——The San Gregorio Mining & Railway Co. was organized in New York to take over the San Gregorio mine and a local railway that starts at Marfil. This company purposes reopening the mine and prospecting other property.——The Mexican Milling & Transportation Co. is to build a standard-gauge railroad 36 miles long to afford transportation to practically all the mines and mills of the Guanajuato district. This is one of the Guanajuato companies of which Geo. W. Bryant is general manager.

Mexico.

The San Matias mill of the Mexican Milling & Transportation Co. has 40 stamps crushing the ore in cyanide

solution through 35-mesh Tyler slotted screens. This is followed by concentration over Wilfley tables, the middling passing to Frue vanners and the tailing to cement slime plates. The coarse tailing is re-ground in a 14-ft. tube-mill, the product of the latter passing to the cyanide plant, where the sand and slime are separately treated, the slime being treated in connection with agitation and Butters vacuum filters. The mill has a capacity of 5000 tons per month. C. E. Rhodes is superintendent of the San Matias mill and the San Prospero mine.—— The Pinguico mine and mill of the Guanajuato Development Co. are situated four miles from Guanajuato, on the rhyolite bluffs overlooking the valley and plain. What is now the principal Pinguico shaft is 800 ft. deep. It sinks in the foot-wall, the ore being opened by five levels running northward on the vein. These levels are 73, 103, 125, 145, and 185 m. respectively from the surface and they represent 1200 m. of drifts on the vein. The levels are all connected by raises and winzes every 50 feet.

The principal ore-shoot is stated to be 10 m. wide, the value of the ore averaging 2000 gm. silver and 20 gm. gold per ton. The vein matter is soft, requiring timbering. As the work proceeds north the vein becomes narrower and the ore hard, there being rich streaks 2 m. wide, assaying as high as 20 kg. silver and 200 gm. gold. This shaft is equipped with an Ingersoll-Rand compressor, electrically driven; a 150-hp. electric hoist, machine shop, sampling room, ore-bins, and a railroad track from the bins to the mill. A second shaft, 175 m. deep, situated a short distance from the one already described, is to become the main working shaft. The 40-stamp mill, which treats the Pinguico ores, is about one mile from the mine and is operated by electric motors. In addition to the eight 5-stamp batteries the equipment comprises two Chilean mills, one Bryan mill, Wilfley tables, Dorr classifiers, 30 sections of cement slimers, and cyaniding equipment. With the machinery and devices named, the ore is crushed, classified, concentrated, the coarse re-ground, the sand and slime separated and cyanided. R. L. Armit is general superintendent of the Pinguico mine and mill; G. M. Henderson being the mill foreman.

The Peregrina mine and mill, one of the numerous properties controlled by Mr. Bryant and associates, is about seven miles from Guanajuato. With 120 stamps in operation, the plant treats between 400 and 500 tons of ore per day. The Peregrina ores carry gold and silver in a gangue which in some parts of the mine is hard quartz and in others a decomposed material. In the former the precious metals are associated largely with pyrite; in the oxidized material much of the gold is in a free state and the silver a chloride. The mine is opened through a main haulage adit, 350 m. long, intersecting the series of parallel veins. The ore now being produced is hoisted by electric motors to the main haulage level. The milling method here does not differ radically from the general practice of the district. The table product, resulting from concentrating the heavy material from the batteries, amounts to about two tons per day. The table middling is re-ground in a tube-mill; the lighter slime, overflowing from cone-classifiers, goes to slime-collectors. The re-ground product from the tube-mill passes to cone-classifiers, in which a separation of sand from slime is made. The usual method of leaching the sand in large steel vats and cyaniding the slime in agitating vats follows. Butters filters are employed in drawing the solution from the flocculent slime material; Blaisdell excavators and belt-conveyors are used in discharging the sand after leaching. J. J. Hollister is manager of this property.

Butte, Montana.

The Smoke Suits.— An Injunction Unlikely.— Local Conditions Unchanged.— The Great Falls Smelter.— Schwab and the Corry Claims.—Rapid Shaft Sinking.—East Butte.

The modifications made in the smelter smoke injunction suit by Oliver Crane, Master in Chancery of the Federal Court, are much more favorable to the Amalgamated Copper Co. than the findings in the origiual draft were, and it is claimed that if Judge Hunt approves the findings he may well and consistently refuse to issue an injunction to close the Washoe smelter at Anaconda. The Master finds that no permanent injury has been done the land by the arsenical fumes from the smelter, and that if the smelter were closed for one year all the land would become free of the accumulations, for since September, 1903, when the big stack was completed and put in use, the precipitation in nowise damaged the land. There is a possibility that the present suspension of the Washoe smelter may therefore give the land time to absorb the accumulated noxious substance and solve the question of a permanent injunction. The findings on the question of no permanent damage to the land is emphatic. Judge Hunt is not likely to be able to consider the findings and give a decision within the year.

The condition of the copper market does not encourage the hope that there will be an early resumption of mining by the Amalgamated Copper Co. in the mines that have been closed for several months. While general business conditions appear to be improving there is nothing to justify an increase in production. The Boston & Montana Co., the only subsidiary of the Amalgamated that is mining, has not yet reached its operating capacity, although it was announced at the time of the suspension of the other mines that the Boston & Montana would be worked to full capacity, and would produce the same amount of copper as the other mines had been producing. The North Butte is shipping a limited quantity of ore to the Clark reduction works, but the Butte Coalition is not mining any ore at all. "The reduction works have been handling some of the North Butte ore, and additional converters being installed will make it possible for them to handle more ore, but the entire capacity of the smelter is not great enough for the North Butte normal output, let alone that of the North Butte and Clark mines together," said A. C. Carson, general manager of the North Butte. At the Great Falls smelter of the Boston & Montana Co. the half-time system is being worked, due to the desire of the Amalgamated to give employment to as many men as possible. Men are allowed to work only half time, and in that way twice the number usually employed are given work.

It is understood that the Davis-Daly Estates people are negotiating with an English syndicate for the placing of a lot of Davis-Daly stock, by which the company treasury will receive $1,100,000 cash at once, and $600,000 in deferred installments.—— It is learned that before the financial panic a representative of Charles Schwab was negotiating for the acquisition of the Corry group of copper claims in the district east of Butte, on the main range. The Corrys own a hundred or more claims in that district, and several claims have been opened sufficiently to disclose the copper veins. Schwab offered $1,000,000 for the property, agreeing to pay $250,000 in cash, and give stock for the balance in a company to be organized. The Corrys declined the offer, but it is understood that negotiations have not been abandoned, though they have been deferred.

The Butte-Ballaklava Copper Co., which capitalized six acres of ground for $6,000,000, is sinking a new shaft and also opening the old one on the Burke claim. In

the old workings, at a depth of 510 ft., it has opened a vein which the management claims to be the Edith May vein of the North Butte Co. The vein there is 28½ ft. wide. A cross-cut is being run north from the shaft, and has also intersected another vein. It is claimed that picked samples of the ore assays 18% copper, 30 oz. silver, and $1.20 gold. It is the intention of the company to drift east and west on the vein, the west drift to be carried 500 ft. to connect with the new shaft. The new shaft is down 300 ft., and fair progress is being made with the temporary plant. The company intends to install a new plant, and the equipment will include an electric plant for the operation of compressor and pumps.——The record for shaft-sinking in the Butte district probably belongs to the Pilot-Butte Mining Co., which sank a four-compartment shaft 250 ft. in two months. The shaft on the Pilot is now 515 ft. deep, and a station is being cut at the 500. At the 500 in the Elm Orlu, an adjoining property, a big vein of copper-silver ore has been opened by W. A. Clark, and on the 700-ft. level a big body of copper glance has just been found.

Salt Lake, Utah.

A Mine-Owners Association.—The Yampa Smelter.—Another Consolidation.—Dividends.—Shipments From Tintic.—Lower Mammoth Co.—Less Demand for Coke.—Boston Consolidated.—The Mascotte Adit.—Smelter Fumes.

The mine-owners have effected an organization which is to be known as the Utah Mine Operators Association. The president is John Dern, of the Consolidated Mercur Gold Mines Co.; Thomas Kearns, manager of the Silver King Mining Co., is first vice-president; W. F. Snyder, manager of the National Development Co., second vice-president; Harry S. Joseph, manager of the Silver Shield Mining Co., secretary; C. E. Loose, manager of the Grand Central Mining Co., treasurer, who, with Lafayette Hanchett, W. C. Alexander, George W. Riter, and Ernest Bamberger, comprise the executive committee. Various sub-committees have been named, and the organization has settled down to business. About 90% of the operating mines of the State are represented in the organization, which was affected amid much enthusiasm, as the mine-owners are unanimously of the opinion that the existing custom smelting companies operating in the vicinity of Salt Lake have made them victims of arbitrary smelting rates. The new organization has already placed itself on record as favoring the independent smelter movement launched in this city recently, and passed a resolution urging upon Congress to establish a government assay-office at Salt Lake City.

The management of the Yampa Smelting Co., operating a plant in Bingham canyon, has announced the intention of installing a two-stand converter plant, which will make this company entirely independent of all other local smelters. Heretofore the Yampa company has shipped its matte to the United States Smelting Co. for converting.—— The Tintic Mining & Development Co., of which the Yampa Smelting Co. is a subsidiary, will shortly begin work on its Tintic properties after a shut-down covering many years. Recent developments made in the Colorado and other mines has demonstrated that the Tintic property is well situated. It is the intention to sink the shaft to a depth of 1500 ft., and extend intervening levels.—— Negotiations are pending for a consolidation of the properties owned jointly by the Nevada Utah Mines & Smelters Co. and the Ohio Kentucky Co. at Pioche, Nevada. Representatives of both companies are now in the East for a conference on the matter.

Two Utah mining companies have posted dividends within the past week, namely, the Mammoth, for $40,000, and the Utah (of Fish Springs), for $3000.—— Ore shipments from Tintic last week were reduced to 46 carloads, the smallest in eight years, the shippers and amounts being: Centennial Eureka, 38; Tintic Iron, 5; Eureka Hill, 3 carloads.

At the annual meeting of shareholders of the Lower Mammoth Mining Co., operating in the Tintic district, a new board of directors was chosen consisting of A. C. Ellis, J. J. Stewart, John Dern, W. S. McCornick, M. P. Braffett, H. G. Williams, and E. C. Coffin. The mine superintendent recommends that the shaft, which is now down 1200 ft., be sunk to the 2000-ft. level, it being estimated that the orebody will be caught on its dip at about 1900 ft. The financial statement shows that the company sold ore to the amount of $123,467 in 1907, and that $57,000 was disbursed in dividends. It is estimated that the ore in reserve is double that extracted last year.

Owing to the shutting down of so many smelters and mines throughout the West during the past few months, there has been a great falling off in the demand for fuel, with the result that some of the coal companies have begun to curtail work. Some mines have been closed entirely, but as yet there has been no great reduction in the number of miners employed; however, in numerous instances, the men are working only about two-thirds time. The closing of the smelters in Montana and in the Salt Lake valley greatly reduced the demand for coke.

The Boston Consolidated has placed its new surface tramway in commission. It transports the ore to the new concentrator at Garfield. The starting of the tramway has been delayed by the accident to the pumping plant which resulted in the death of L. H. Wheeler, superintendent of construction.——The Mascotte adit of the Dalton & Lark mine which is to be utilized in the future by the Ohio Copper Co., has been pushed ahead to a point within 600 ft. of being directly under the vertical shaft with which it will connect. The adit is now draining the mineralized zone of the Ohio and work is about to be resumed in the shaft. For several weeks the adit has been driven through a well mineralized region, with encouraging assays for gold. The construction of the new mill is going forward steadily. The company recently cleared up its financial obligations and is now prepared to round out its enterprise as planned.

The smelter of the United States Smelting Co. is still being operated; and while the plant may go down for a time, it is claimed that the company is getting ready to go into court to show that if granted a modified decree, as was the case with the American Smelting & Refining Co., as regards its Murray plant, it will be possible to keep within the law; and that such devices have been installed to control the fumes that there is little danger of damage being done to vegetation. Negotiations have been resumed with the farmers with the object of getting them, for a consideration, to sign smoke easements on their lands as they did with the American Smelting & Refining Co. last year. The shutting down of the Utah Consolidated and Bingham Consolidated plants and the dismissal of so many men has had a salutary effect on the farmers and they are not nearly so hostile as they were a few weeks ago. Nevertheless, some of them are hard to pacify. The most recent smoke agitation started has been the filing of claims against the Yampa Smelting Co., operating in Bingham canyon, by the owners of farms ten miles distant from the works. The Yampa management, however, will fight the cases to the bitter end if they are taken into court. It is ridiculous to suppose that the fumes from this plant ever get down into the Salt Lake valley.

Denver, Colorado.

Land Frauds. — Water Famine. — The Portland and Mr. Burns. — Activity at Aspen.—Mining at Boulder.—Leasing Successful at Cripple Creek.

The Federal grand jury returned an indictment charging W. R. Mason and Joseph Vanderweide with conspiracy to assassinate Joseph A. Walker, the secret service agent, whom Vanderweide shot and killed at the Hesperus mine near Durango last November. Indictments were also returned against E. M. Biggs and W. W. Nossman on the charge of conspiracy to obtain 8000 acres of government land by illegal methods for the benefit of the New Mexico Lumber Co. This indictment is similar in import to the ones recently quashed by Judge R. E. Lewis, when he rendered his decision upholding the 'dummy entry' system. The government prosecution has been greatly hampered by the loss of Walker, who was the chief witness in these cases.

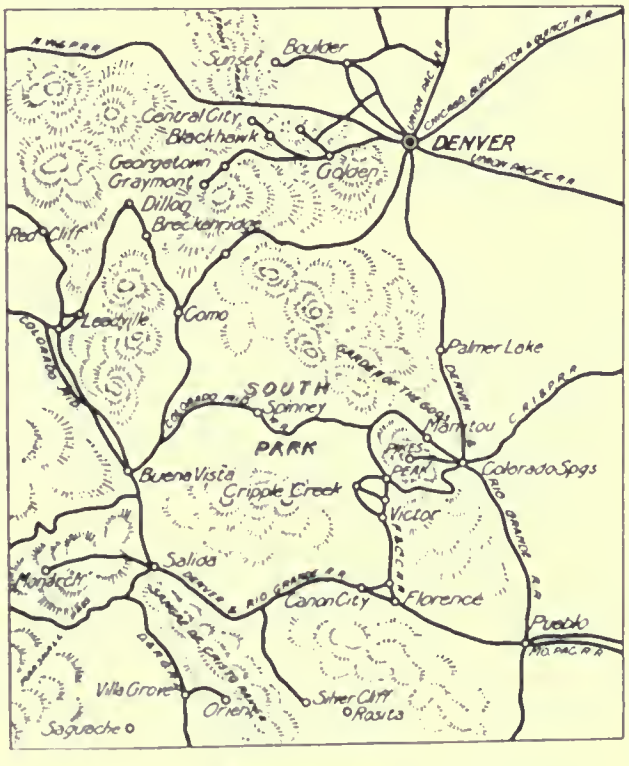
The City of Colorado Springs has given notice to all the industrial plants outside the city limits that by April at the latest they must obtain their water supply from outside sources. This will affect the big reduction plants especially. It was only after much consideration that the City adopted this course. Colorado Springs is growing so rapidly that in case of a serious fire under the present conditions the water-supply would be inadequate and the City would be liable for damages.

The latest development in the struggle for the control of the Portland Gold Mining company is the demand of J. F. Burns, made to the State Commissioner of Mines, that Deputy Inspector McCarty be removed from office. Inattention to duty and an unfair report about the Portland mine are the charges.

The Aspen district is showing renewed activity in prospecting and development work. The Smuggler and Durant mines have kept their pumps going and a small number of miners at work ever since the shut-down on December 7. These mines are now increasing their working force and are ready to start as soon as the market warrants. The machinery necessary to complete the mill at the Ruby mine is on its way. Everything is being made ready for extensive operations on this property in the spring. The Balarat-Smuggler mine at Boulder is being re-opened by H. S. Vaughn and associates of Denver. The property has been purchased for $100,000. This mine has been idle for several years, although it was once a famous producer of lead-silver ore. Men are now at work clearing out the mine and repairing the buildings. The Empire Zinc plant at Canon City has been closed until the market for spelter improves.

The Gold Sovereign Mining & Tunnel Co. of Cripple Creek is getting affairs badly mixed up. Litigation is now threatened by the Franklin Mining Co. of Denver. The deposed Rapp management gave a three-year lease to this company. The stockholders rescinded the acts of the Rapp management at their recent meeting and the new board of directors has given a two-year lease to the Colorado State Investment Co. In its endeavor to escape from poor management, the company seems about to be involved in litigation which may prove worse. The success attending the leasing system in the Cripple Creek district has made the lessees particular. They hesitate to take a lease that does not show ore in plain view. On the other hand, the owners are increasing the royalties. The El Paso Consolidated is finding itself in this difficulty. The lessees who have been awarded blocks of ground are for the most part ready to give up their leases because of the poor showings and the almost prohibitive royalties. Every mine in Cripple Creek is now operating with a full force of men, and it is the first time in many months that idle miners could be found in this district. The great influx of miners from Nevada has caused the executive committee of the Mine Operators' Association to be very watchful and they are now personally examining and passing on all applications for recommendation cards.

Dividends of record paid by mines of the Cripple Creek district amounted to $1,129,145, with an additional estimated earning of close companies of $250,000 for the year 1907. The production for the year was 608,459 tons, valued at $13,148,152, bringing the total value to the beginning of 1908 to $232,793,443. After the fire at the Golden Cycle mill, the output of the low-grade properties suffered, but December showed a large improvement, there being a net gain over November of nearly



A Part of Colorado.

6000 tons, and a profit of $100,000. With the new treatment charges from the smelters, and the resumption of the Golden Cycle mill the new year opens cheerfully. The number of men employed is at high-water mark, and the payroll for December was the largest in many months; there is a surplus of labor, although much new development work is under way, and many of the new comers are turning their attention to leasing. The Eagle Ore Co. is employing two shifts of millmen, handling an average of 800 tons per day. The record for an 8-hr. run at this sampler was broken on the 7th, when 510 tons of ore were handled. The Taylor & Brunton sampler is operating steadily on one shift, with frequent overtime runs.—— The Stratton's Independence, Ltd., Co.'s cyanide plant is under cover, and machinery is arriving daily, a very businesslike activity prevailing; a trial run will probably be made in March, depending on the prompt arrival of machinery.—— The Cresson property on Raven hill reports a strike of high-grade ore, from which shipments returned $10.50 per lb. on several hundred pounds; the strike is of interest also owing to the unusual character of the formation, being in granite in a region noted for its phonolite and porphyry. The Cresson has some large ore-shoots, and the new one appears to be as persistent as the others.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A FRESH WORLD'S RECORD for vertical shaft-sinking with hand labor was created in July, 1907, at No. 2 shaft of the Brakpan Mines Co., Transvaal; the shaft was sunk 201 ft. during the month.

THE most practical method for examining the quality of finished concrete work is by sampling the material by taking out a core with what is known as a shot-drill. With a small hand-power outfit, a hole can be bored into the concrete very rapidly, a core removed, analyzed, and the character of the mixture accurately determined; the holes can be easily filled and do not injure the strength or appearance of the work.

A METHOD for the extraction of petroleum from boreholes that is used by the Galician Carpathian Petroleum Co. at Kryg, in Galicia, consists of passing a continuous band of rope through the borehole; this absorbs the oil, and the saturated portion of the rope is then compressed between cylinders or rolls at the surface. The hemp-band employed is similar to a mine-cage cable, covered with a fibrous material to make it permeable to liquid. It is in three sections, jointed by stitching with shoemakers' waxed thread, which facilitates repairs. It is 80 mm. wide and 8 mm. thick. At Kryg, owing to local circumstances, the apparatus is worked by hand. The amount of oil poured into the tank by compressing the rope is about 415 gm. per current metre. It is said that the method can be utilized for acid-solutions, brine, or even drainage of mines.

To prevent the occasional occurrence of fire in air-compressor cylinders, due to oxidation of the oil used in lubricating, these cylinders should be cleaned frequently. This may be done by filling the oil-cup with soap-suds made of one part of soft soap to fifteen parts of water; the compressor may work a few hours, during which the solution should be liberally fed; then open the receiver blow-off and drain off the accumulation of oil and water. Care should be taken to feed with oil a half hour before shutting down, so that the parts may not be subject to rust. The intervals at which this cleaning process should be repeated depend on the service of the compressor. If on a light load and running for 8 to 10 hr. per day, once every month or two will be sufficient; but if running at full capacity for 24 hr. per day, about once every week or two is necessary.

THE commercial value of asbestos is determined by the strength of the fibre and by its length. Common varieties from localities in the United States are usually brittle, being easily broken in the fingers, while the best quality of Canadian chrysotile asbestos is tough and can be broken only with difficulty. If of the latter quality, a large deposit 20 miles from a railroad in the United States would have commercial value if occurring under average conditions as to mining and hauling to the railroad; but the 20-mile wagon-haul would prohibit the profitable working of a deposit of medium quality. The market quotations are for prepared asbestos. The preparation is expensive and requires a costly plant. Although asbestos occurs in many places in the United States, very little has been mined. The Hance Asbestos Co. in 1905 and 1906 worked a deposit at the bottom of the Grand Canyon in Arizona, and the American Asbestos Co. produced in 1906 a small amount of amphibole asbestos from its mines near Chestnut Fork postoffice, in Virginia. Canada yields by far the largest proportion of the world's production of chrysotile asbestos. The principal deposits are at Black Lake, Thetford, Templeton, Danville, and East Broughton, in Quebec. Italy, Russia, and South Africa produce some asbestos, but all of it is inferior to the Canadian.

A PARTICLE of placer gold, if flaky in shape, may be exceedingly light in weight and yet be readily seen against the black iron of a gold-pan. Near the mouth of the Torio river on the Pacific coast of the Isthmus of Panama, there is a deposit of beach gravel several acres in extent, which contains many exceedingly fine colors of gold. They are distributed with comparative uniformity; each panful of gravel yields about 200, as has been determined by occasional counting. About 1200 colors were weighed and found to aggregate only two cents in value; at this rate 60,000 colors would be required to make one dollar. The display of this flaky gold in the pan might lead the unwary prospector to think he had found a valuable placer deposit; in truth, the gravel probably contains a value of only 40c. per cu. yd., and on account of limited size, character of the gold grains, and other conditions, cannot be profitably worked.

BENZINE is used at the Komata Reefs mine, in New Zealand, in the place of the usual blacksmith forge for drill-sharpening. The storage-tank is situated in the mouth of a disused adit, about 100 ft. above the smithy, and this head gives ample pressure. The furnace, which is rectangular in shape, is in outside measurements about 32 in. long, 12 in. high, and 6 in. wide. It is made of cast-iron plates lined with ordinary firebrick. A Cary burner is placed at one end of the furnace and the blast is directed longitudinally through its centre; an opening at the other end is fitted with a 1½-in. pipe for carrying off the products of combustion. The furnace takes 18 drills on each side; they are introduced through slots and supported on light iron stands. The cold steel is put in at the end farthest removed from the burner and is gradually moved toward the other end as the heated drills are taken out. An average of 2700 drills sharpened during two shifts with three men on each shift has been attained. Either a 1¾ or 2-in. burner is used and the benzine-consumption is approximately 1 gal. per hr. This furnace has given no trouble although it has been running nearly two years.

A SIMPLE method by which the presence of tungsten in a rock may be determined is as follows: The ore should be ground to a fine powder; when it is of low-grade material the tungsten mineral should first be concentrated by washing away the lighter portion, as in panning gold ore, which is not difficult as the tungsten minerals are all heavy; then the concentrate can be dried and ground until fine. Some of the powder is then placed in a test-tube, hydrochloric acid is added, and the contents of the tube are boiled for a short time. If scheelite is present it will be sufficiently decomposed in one or two minutes, but wolframite and hubnerite may require boiling for five or ten minutes. If tungsten is present it is liberated as a yellow precipitate of tungstic acid. Frequently the precipitate assumes an olive-green color. Even when a yellow precipitate is present it cannot be relied upon as a test for tungsten as it sometimes consists of ferric chloride. Having boiled the contents of the tube for a few minutes, remove from the source of heat and add a little granulated tin, or a piece of tin-foil rolled up; this immediately commences to dissolve, and if tungsten be present the solution will within a minute or two assume a beautiful deep blue color.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

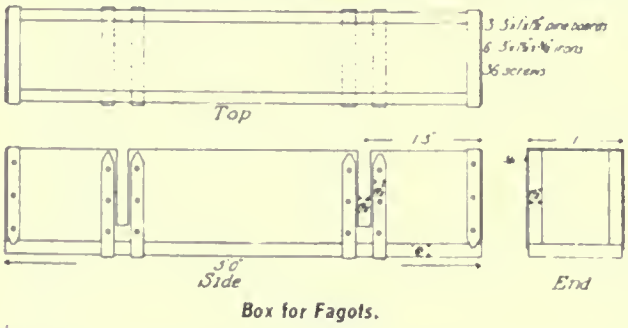
Use of Brush as Fuel in Roasting.

The Editor:

Sir—The photograph illustrates a load of brush fagots or *monojos*, as the Mexicans call them. To a great extent we have substituted these for first-class wood in firing our boilers, and are using them entirely as fuel in our hand reverberatory roasting furnaces. Our first-

Unloading Fagots at the Roaster of the Progresso Mining Company.

class wood costs about P11 per cord of 3.624 cu. m., delivered in the *hacienda*, and we effect a saving of about 20% in cost of fuel by using the fagots in roasting. Besides effecting this saving, the source of our fuel supply



Box for Fagots.

is greatly increased, as there is a heavy growth of *Uno de Gato*, *Palo Arco*, and various other kinds of brush in the immediate vicinity of the *hacienda*. It is advantageous also to clear the ground and give the grass a better chance to grow, giving the freight mules more freedom in grazing, besides being a safeguard against fires, which are rather frequent.

The brush can be burnt very green and gives a long flame, and is not as likely to burn out the grate-bars as is the case with the first-class wood, which makes very hot coals. The fagots are made as follows: Two pieces of fibre plant, such as *heniquen* or *datil*, are placed in the slots in the box, which is shown in the drawing. Then two short rawhide ropes, with iron rings on the ends, are laid across the slots. The brush is then jammed into the box and cinched at both ends (with the rawhide ropes) into compact fagots, and tied firmly with the fibre leaf. It is pulled out of the box, the ropes taken off, and is ready for use.

These fagots are made by contract at two centavos apiece, and we have 50 men employed at this work. Since the drawing was made, we have made a slight change in the design of the box, by using 2-in. planks, instead of 1½-in., and re-enforcing the boxes with 1 by 4-in. strips of wood, instead of with iron straps. Size of box inside is 9 in. wide by 12 in. high and 5 ft. long.

ARTHUR C. NAHL.

Triunfo, Baja California, December 23.

Iron Screen in Zinc-Boxes.

The Editor:

Sir—It will probably create some surprise among cyanide men to be told that iron screens in zinc-boxes are detrimental in as much as they facilitate solution of zinc both by cyanide and caustic soda. Some time ago I attempted to form sodium-zincate by dissolving zinc shaving in caustic soda. The action was not as rapid as I wished and expected, and on consulting Bloxam I found that contact with iron increased the rapidity of action. A simple test demonstrated this to my entire satisfaction. The action was increased a hundred fold.

The question instantly occurred to me: "Why use iron screens in zinc-boxes? There is always more or less caustic soda present." I have since run parallel boxes with and without iron screens. Conditions were maintained as nearly identical as possible with that exception. The results show a saving in free cyanide, as well as zinc. Average analyses over a considerable period show as 0.08 lb. cyanide and 0.05 lb. zinc per ton of solution in favor of new iron screens. It remains to find a satisfactory substitute. I used for the test burlap, perforated zinc sheet, and cocoa matting. None of these are satisfactory for permanent use. Perforated fibre-board would probably fill the bill.

The idea may not have a wide application, but where solutions contain as high as 0.1 to 0.125% free cyanide, it is well worth considering. I quote E. M. Hamilton in saying: "The principle has been proven beyond doubt."

JAMES S. COLBATH.

Torres, Mexico, November 16.

Cyanidation in Nevada.

The Editor:

Sir—The article by Mr. R. S. Browne in your issue of November 30 brings up a subject of extreme interest at this time when smelter rates have been raised so high and settlements deferred so long as practically to prohibit the shipment of ore, and it is to be hoped that those metallurgists who have studied the Goldfield ores will publish such data as they may have, that methods of treatment will be brought forward and compared, to the end that properly designed mills may be erected and independence from the smelters established.

In furtherance of this idea I am pleased to give some

data on tests recently concluded on ores furnished me by the Goldfield Con. Mines Co. and to outline the method of treatment that appeals to me as most economical.

The ore was the characteristic sulphide ore of the Mohawk vein, being very silicious and carrying about 8% sulphides finely disseminated throughout the matrix. These sulphides, besides the iron pyrite, contained tellurium in appreciable quantity, arsenic, and traces of copper. [Since writing the above I see that Mr. E. A. Collins questions the presence of tellurium. I can state for his information that in these samples the tellurium was determined positively by chemical analysis. Also that on a notable shipment of Bonanza ore the analysis showed 2.42% tellurium and 2.00% gold indicating the mineral calaverite, and I have reason to believe that the greater part of the gold in the low-grade sulphide ore is present as a telluride.]

Former tests upon the oxidized ores had given 94% extraction by simple fine grinding and agitation (as shown in a former article in your issue of August 25, 1906), and with this idea in view a portion of the ore was ground to 150 mesh, properly neutralized and agitated with 0.25% KCN solution. The extraction, however, was so poor that further efforts in this direction were abandoned.

A series of tests was then made using what Mr. Browne has seen fit to term the Nevada wet method, that is, the ore was ground to 40 mesh, amalgamated and then concentrated, the tailing was re-ground to 150 mesh, again concentrated, and passed to agitators with 0.25% KCN solution.

The results of these tests varied considerably and depended upon most careful and perfect concentration. The best results obtained by this method showed a final extraction of 92% on ore assaying 2.5 oz. gold, worth $51.67 per ton, distributed as follows:

	—Per ton of ore.— Oz.	Value.	Per- centage.
By amalgamation	0.108	$2.16	4.20
By first concentration on 40 mesh obtained 6.43% worth $398.07 per ton of concentrate, equal to		25.60	49.54
By second concentration on 150 mesh obtained 2.5% concentrate worth $188.07 per ton of concentrate, equal to		4.70	9.09
By cyanidation		15.08	29.18

Cyanide consumption 2.6 lb. per ton. Residue assay, 4.13.

The difficulty of getting regularly the perfect concentration so necessary to the success of this process, led to tests by roasting. A number of tests were made crushing to 10 mesh, roasting, and leaching. These showed extractions as high as 87.5% with a cyanide consumption of 1.6 lb. per ton. The ore in roasting lost 13% by weight.

The next tests were to re-grind to 30 mesh after roasting at 10 mesh and then amalgamating, concentrating any heavy oxides, and leaching the tailing with cyanide solution. Some of these tests gave good results, the best extractions being as follows:

Roasted heading assayed 2.82 oz. gold, worth $58.29.

	—10 mesh.— Extracted.	%	—30 mesh.— Extracted.	%
By amalgamation	$18.40	31.56	$26.04	44.67
" concentration	3.24	5.56	9.35	16.04
" cyanidation	32.50	56.80	21.25	36.46
Total extraction		93.92		97.17

Residues assay $4.13 on the 10 mesh, and $1.65 on the 30 mesh.

These were given four days leaching.

Another test without amalgamation and concentration, but re-grinding the roasted 10 mesh to 30 mesh, gave equally good results by direct cynanidation, the extraction being 97.2 per cent.

While these tests as regards extraction were all that could be desired, considerable trouble in leaching was encountered. The slime formed in re-grinding caused extremely slow percolation and a tendency to channel, and many of the tests showed great irregularity from this cause. It was evident that in practice it would be necessary to separate slime from sand and as this would complicate the plant, further tests were made by re-grinding the roasted 10-mesh ore to slime or to pass 80, 100, and 150-mesh screen, agitating in 0.25% KCN solution for 12 hours and obtaining the following extractions:

Ground to 80 mesh	95.8 %
" 100 "	97.6 "
" 150 "	96.4 "

KCN consumption being 2.0 lb. per ton of ore.

These last results were so regular and so satisfactory that unless mechanical difficulties, high costs, or other objections were found, I should consider it by all odds the best method of treatment.

Let us then consider the mechanical arrangement necessary for such a method of treatment and see if there are any well founded objections too serious to overcome. Such a scheme of treatment involves:

1. Coarse crushing in breakers.
2. Drying the ore. (This may not be necessary when grinding to 10 mesh.)
3. Dry crushing to 10 mesh.
4. Roasting.
5. Re-grinding to 100 mesh.
6. Agitating.
7. Filtering solutions.

The bugaboo of dry crushing and the prejudices against it are readily excusable if one considers the many attempts with the old jarring rolls and the endless trouble with screens and elevators, not to speak of the dust nuisance. But improvement in dry-grinding machinery has kept pace with other metallurgical improvements, and as we have taken from the cement works the tube-mill, so may we find there our intermediate grinder. I refer to a new class of ball-mill called the kominuter manufactured by F. L. Smidth & Co. This mill has been successfully used in many of our new cement plants. Their large capacity per horsepower consumed cannot be equalled by the best of our stamp-mills crushing wet to the same mesh, and, being self-contained, the dust is almost negligible and easily controlled. In one large cement plant in which these mills have been used for three years the costs for the year 1906 were $0.0107 per bbl. of 380 lb. taking a feed of hard clinker passing 1½-in. ring and grinding to pass a 20-mesh screen.

In a personal communication from Mr. John Tait Milliken, superintendent of the Golden Cycle mill, at Colorado Springs, where four of these machines were installed, he informs me that during the time they ran prior to the fire they obtained a "capacity of 17,000 lb. per hour for each mill when fed with a product that had been reduced by rolls to pass through an opening 1½ in. diam." (revolving screen ¼-in. steel plate). These were No. 66 kominuters and "were equipped with a diagonal slotted screen, size of opening 5/32 by ½ in. No. 8 steel plate. This opening gave a product varying in size from ¼-in. cubes to the finest slimes and when discharging this product at the above-mentioned tonnage, the consumption of power was 50 hp. at a speed of 22 r.p.m., the ball consumption being fourteen 5-in. forged steel balls weighing about 19.5 lb. each per day of 24 hours." Mr. Milliken estimates that "1 man per shift can operate and carefully watch 6 or more of these kominuters," and that the liners will last about 2 years. Mr. R. N. Diggles, metallurgist, who visited the Golden Cycle mill just prior to its destruction, tells me that they gave no difficulty from dust.

With these facts before us, may we not stop and consider before rejecting dry crushing?

The next step in our scheme is roasting. In the past, roasting has had two main objections, high costs due to expense for fuel and labor, and unreliability as regards the product, for cyanidation, above all other processes, requires a perfect roast. The prejudice against roasting is probably due more to imperfect roasting furnaces and the many resultant failures in the past than to any other cause. Many of the furnaces that gave most satisfactory results for smelting failed utterly when tried at the cyanide plant. But there are one or two furnaces that have been perfected in Australia and which are now rapidly finding favor in this country and Mexico. I refer to the Edwards and Merton furnaces.

On samples of roasted concentrate taken from the Edwards furnace at the Eagle-Shawmut mine, in California, the roasts were so perfect that less than a pound of lime was required to neutralize the acidity. This concentrate before roasting carried 35% sulphur and after roasting the calcines contained less than 0.25% sulphur. This was accomplished in a 57 by 6 ft. tilting furnace roasting 9 tons per 24 hours and using 13½ gal. fuel-oil per ton of concentrate.

At the Golden Cycle mill four of these furnaces of the Duplex style were operating most satisfactorily and four additional ones, I understand, are to be added to replace other types formerly used. Mr. Milliken favors me with the following data: "Each furnace has an effective hearth-area of 111 by 13 ft. The average sulphur content of ore fed to furnace is 1.8%. Each of these furnaces had an average capacity for the month of July of 107 tons per day of 24 hours, and required 280 lb. lignite coal per ton of ore roasting down to 0.11% insoluble sulphur, and 0.15% soluble sulphur. For the four furnaces the consumption of power was 15 hp. and required the services of one man per shift of eight hours for firing. So far as we can see from our period of operations the repair should not exceed, under ordinary conditions, five cents per ton."

The Merton furnace has also been quite successful in Australia, but I have no data in regard to it. However, I imagine that the dust lost in a Merton would greatly exceed that of an Edwards, in which it is almost negligible. Certainly the Edwards shows up well and answers all our requirements.

We have still to consider the cost of fuel. I take it that California oil is the cheapest fuel delivered at Goldfield, and though I have heard it stated that oil could not be obtained at any price, I have secured quotations on a two-year contract basis, delivered in carload lots f.o.b. Goldfield, and guaranteeing deliveries at the rate of 150 bbl. per day at $2.75 per barrel. Taking the heat values of lignite coal as used at the Golden Cycle mill, this would mean one-third of a barrel of oil per ton of ore. This is slightly in excess of the amount used at the Eagle-Shawmut on heavy concentrate with the small furnace. Assuming this to be correct, the fuel cost would be about 90c. per ton of ore; 35c. additional should easily cover power, labor, and repairs, or a cost of $1.25 per ton for roasting—which can hardly be considered prohibitive.

From the roasters, after cooling, it will be necessary to re-grind to 100 mesh. For this the choice of machines probably lies between the tube-mill and grinding pans of the Wheeler type. Metallurgists are divided as to which is the most suitable for re-grinding roasted ore. Australian practice seems to favor the pan, but this is probably due to the desire to amalgamate while grinding in order to eliminate the coarse gold. This brings up the question of Viator: "How to treat ores carrying some coarse gold as well as fine gold," as discussed in recent issues of the MINING AND SCIENTIFIC PRESS.

In the discussion on the 'Treatment of Desert Ores,' MINING AND SCIENTIFIC PRESS, August 25, 1906, I then advocated the elimination of amalgamation from the scheme of treatment whenever it was found necessary to fine-grind the ore to obtain the maximum profitable extraction and, to prove my contention, I gave the results of some tests conducted at that time. Since then I have had occasion to test the same thing on many ores and have as yet found no instance where I could not obtain just as high an extraction by fine-grinding to 100 or 150 mesh and direct cyanidation, as the total extraction obtained by both amalgamating and cyaniding. To give a particular example: Last summer I was working on a very rebellious ore containing coarse gold as well as fine gold. The ore consisted of a gangue of quartz containing about 5% arseno-pyrite and considerable arsenious oxide. It resisted all attempts at treatment raw, including amalgamation, concentration, and cyaniding. Roasting was therefore decided upon. After roasting at 10 mesh it was leached for four days, washed, then re-ground to 60 mesh, amalgamated, and concentrated to save any heavy oxides containing value. In this ore some of the gold particles were so coarse that they could be picked up with pincers, but they resisted amalgamation (due to a coating on the gold) and it was found to give a higher extraction when amalgamation followed rather than preceded cyanidation.

By this method the ore assaying 3.67 oz. gold per ton gave a final extraction of 96.1%, the residue assaying 0.15 oz. worth $3.10 with a cyanide consumption of ¾ lb. per ton of ore.

Another test without amalgamation and concentration, but re-grinding the roasted 10-mesh ore to 100 mesh and agitating for 12 hours with 0.25% cyanide solution gave an extraction of 98.8%, the residue assaying 0.045 oz. gold worth $0.92, with a cyanide consumption of 0.4 pounds.

It would seem to me, from these and many other tests, that amalgamation is only an added expense if fine-grinding is to be resorted to, and this being so the tube-mill offers more advantages than the pan, especially for large installations. I should take my cooled ore, feed direct to my tube-mill with full strength cyanide solution, and in the great majority of cases it would be unnecessary to grind finer than 100 mesh to obtain a maximum extraction.

This brings us to the agitators. Of the many means and appliances for agitating slime nothing appeals to me, for cheapness and simplicity, so much as the air-lift pump set in a conical-bottom vat. Under these conditions the air-lift is working at its maximum efficiency, that is, the down-take is practically equal to the up-take. This system is too well known to require description and has been successfuly installed to agitate not only slime but heavy concentrate finely ground. It presents the advantages of having no moving parts and requiring a minimum of power.

From the agitators we come to the subject of filters. At present the vacuum-filters seem to find favor in America and Mexico, though Mr. C. W. Merrill has accomplished wonders with filter-presses at the Homestake.

There are several good vacuum-filters on the market, such as the Moore, Butters, Kelly, and Ridgway, all of which do excellent work and would answer our requirements. But these filters have one serious drawback. As cloth is the filtering material used by them, at the commencement of each charge the filtrate is turbid and in many instances this turbidity persists all through the

operations owing to the presence of a small hole in one or more of the filter-cloths. Also an incrustation of carbonate of lime accumulates on these filter-cloths and this progressively impairs their permeability. For efficient working, therefore, a subsidiary filter has to be used to clarify the solution, and the cloths have to be periodically pickled in acid to remove the lime incrustation.

A machine to which these objections do not apply, and which appeals to me strongly on account of its simple effectiveness and low first cost is the invention of Mr. Bertram Hunt. In its simplest form this consists of an annular chamber, which can be made of concrete, the top of which constitutes the filter surface. This filter surface is Hunt's well-known triangular-slat-sand filter, carefully screened coarse sand being used. The inner and outer peripheral walls of the filter are continued three inches above the surface of the filter and constitute tracks on which a carriage revolves. This carriage has a scraper in front which removes the residue and is followed by a distributor for clean sand and one for the slime. Pipes distributing wash solutions and wash-water follow the carriage round the circle at proper distances. In operation, the pulp is preferably first roughly classified so that a portion of the sand in it is separated in a clean condition and this clean fine sand is fed onto the filter surface by the first distributor immediately behind the scraper and the slimy balance of the pulp follows from the second distributor. In this manner the slime is always distributed over a filter surface of fine clean sand which is continuously renewed and removed. This, being a continuous machine, requires little or no attention after it has once been adjusted as to feed of pulp and speed of carriage, and a small part of the time of one man is all that would be required. A machine 16 ft. in diameter has a rated capacity of 50 tons in 24 hours and requires less than 1 hp. to drive and 4 hp. to maintain the vacuum. The machine complete can be installed for a small fraction of the cost of a machine of intermittent type of equal capacity and has the advantage that sand and slime can be treated together on the same machine and at a less cost for repairs, labor, and power.

This completes our process except the precipitation and refining of the bullion, and in this I would follow the usual custom of zinc-box precipitation.

Let us now make a rough comparison of the dry and wet methods. From the data given, I believe it will be admitted that dry-crushing in kominuters to 10 mesh will be as cheap, if not cheaper, than wet-crushing with stamps, and when it is considered that one of these mills complete, with feeders, liners, and balls, costs less than $4500 f.o.b. factory, the comparison with the stamp-mill and its high cost of erection is still more in its favor. As against the cost of roasting we have the cost of concentration and the additional cost of marketing the concentrate. According to my tests 58% of the assay-value could be saved by a series of reductions and concentrations (and this, owing to the careful adjustments necessary and the close attention required, is not always obtainable in the every-day working of the mill). Of the 58% the smelters will pay but $19.50 per ounce of the gold contained as against $20.67 per ounce if shipped as bullion. This is equivalent to 95% of the value, that is, 5% of the 58% must be deducted from the total recovery of 92%, which reduces it to 89.1%, a total difference in the extraction as compared with the method I propose of 8.5%, which on $50 ore amounts to $4.25 per ton. To this must be added a freight and treatment charge of at least $35 per ton on 8.9% of concentrate, amounting to $3.10 per ton of ore, or a total charge against the wet method of about $7.35 above the actual cost of treating the ore. As against this the principal additional cost by the dry method is the cost of $1.25 for roasting. There is also to be considered the greater capacity of tube-mills grinding 13% less weight (loss in roasting) on material made softer by roasting.

In advocating a process against which such strong prejudices have been entertained, I have felt it incumbent upon me to go quite fully into details.

LOCHIEL M. KING.

San Francisco, December 16.

COPPER PRODUCTION.—The American Smelting & Refining Co. and its affiliated concerns, the American Smelters Securities Co. and the Guggenheim Exploration Co., is a growing factor in the copper world. This is apparent from the following figures of production by the American company's smelters during the past three years:

Year.	Short tons.	Refined copper. Lb.
1907	47,300	91,600,000
1906	42,905	85,810,000
1905	36,476	72,952,000

This copper production has come from custom ore. Had it not been for the reverses to the mining industry in the last quarter of the year the copper output of the Smelters trust would have been well above the 100,000,000-lb. mark. The production of copper from the American company's smelting plants during 1908 should be materially increased, as this year it will get the full benefit of the production from its big Garfield smelter in Utah. This is the only copper smelter now operating in the State, and is now turning out copper at the rate of about 72,000,000 lb. per annum, much of it from the treatment of the Utah Copper Co.'s concentrates. The copper production of the American Smelting & Refining Co. is sold in part by the United Metals Selling Co., but the major portion is sold by the American Smelters Securities Co. direct to the trade.—*Boston News Bureau.*

MAGNESITE MINES OF CALIFORNIA.—The only State in the Union thus far producing magnesite in commercial quantities is California, whose output is about 4000 tons per year. This comes chiefly from the group of veins four miles northeast of Porterville in Tulare county, which are being worked by the Willamette Pulp & Paper Co. The veins occur in a brown serpentine. The American Magnesite Co. in 1906 worked a deposit 32 miles southeast of Livermore. The veins stand out prominently and as they are almost dazzlingly white, they can be seen from the higher hills, miles away. One outcrop is 40 ft. wide and traceable through a distance of several hundred feet. Mining is carried on by means of an open-cut. The Walters magnesite mine on the east side of Pope valley in Napa county has made no production for several years, but with improved transportation facilities might become an important source of this mineral. The veins stand up boldly and can be seen from any part of the valley not hidden by hills. One vein at its widest exposure is 10 ft. thick, of which about 5 ft. is solid white magnesite. In another vein 18 in. to 5 ft. of clear magnesite is exposed. Three of the veins can be definitely traced for distances of 140, 250, and 230 ft., respectively. Besides the mines mentioned there are in California several dozen known magnesite deposits, but most of them are too far distant from railroad lines to be profitably worked.

PROSPECTING at the Napa Consolidated quicksilver mine in 1906 was carried on largely by boring with the Calyx drill. Forty-one holes were bored; the results were unsatisfactory as a whole although some indicated good orebodies and it was proposed to prove these indications by further development.

Puddling a Wet Shaft.

Written for the MINING AND SCIENTIFIC PRESS
By HENRY BOURSIN.

The followiug account of how one mine manager puddled a wet shaft is submitted as being of interest to those who have similar work to do.

The Willow River Mining Co. is operating a drift-gravel mine near the head of Willow river, six miles from the town of Barkerville, in Cariboo district, British Columbia. The pay-gravel in this mine is on, and near, the bedrock in the deep channel of the present stream. The depth to bedrock being 107 ft., and the surface gradient of the valley very flat, the mine is worked through a shaft.

In the autumn of 1905, this three-compartment shaft, 7 by 16 ft. in the clear, had been sunk 91 ft. through gravel, and a few feet into rock; and two tunnels had been run out at that level to exploit the channel. Of course, the bedrock was lost in these tunnels, and, by sinking two blind shafts, or winzes, was found at 13 ft. in the deeper one; but the quantlty of water encountered made it impracticable to determine exactly the depth of the channel by this means. That the main shaft was not deep enough for a drift therefrom to bottom the channel, was the inexplicable error of a former manager, who had drilled the ground with an American well rig to ascertain the position and depth of the channel, and sunk the shaft, presumably, on the data obtained in drilling. The error havlng been dlscovered, it became necessary to sink the shaft deeper, and, the depth of the channel not belng known, the additlonal depth of shaft decided on was 25 feet.

The equipment at this shaft lncludes two 18-in. Cornish pumps, driven by a 28-ft. overshot water-wheel, with 7-ft. breast, and, on November 14, when the work to be described was begun, they were on the maximum (8-ft.) stroke, and running 10 strokes per minute, that is, raising approximately 2000 gal. per minute.

With half the inflow stated, deepening the shaft without puddling would have been exceedingly slow and costly, but with the pumps working nearly to their capacity, the shaft could not have been deepened at all without puddling. There was one of two things to do, namely, either resort to puddling, or cease underground work until the cold weather of winter had materially lessened the inflow of water. Therefore the pump compartments were puddled and the centre compartment sunk dry, as shown in the accompanying plan and section.

The first preparatory work was to overhaul the pumps so as to avoid, as much as possible, delays caused by repairs during puddling and sinking. Then the weight of the pumps was put on the shaft-timbers by yokes placed under the flanges of the pump-column, so that the rock beneath the pumps would have the least possible weight to support.

The underground force was then apportioned into two shifts instead of three, working from 7 A. M. to 11 P. M., to enable the manager personally to direct that part of the work requiring the most care. The men were loyal—none more so—but this was the first puddling any of them had ever done; and, as there seemed to be only one man who believed it could be done there and then, it was up to him to see that it was done exactly as he wanted it; hence, with the exception of time for lunch and supper the manager was down in the hole from about 8 A. M. to 11 P. M. until sinking began.

The rock was favorable, being Cariboo schist, compact, and medium hard; that taken from the sides to make room for the troughs, and the first four feet of sinking, was gadded almost entirely, powder being used only when streaks or bunches too hard to gad were encountered, and not more than ½ in. to a shot. Of course, the amount of powder was increased as it became safe to use it. The under edges of the two-inch planking, placed horizontaly to enclose the improvised sumps and help retain the puddling, were carefully filled, as were all joints. The planking was nailed to posts spiked to the bottom sets. The sawed lagging completing the partitions were 'sniped' to one inch thickness on the points, and a neat mat of burlap nailed on the tips.

It is impossible to clean all the sediment from the bottom of a sump containing 18 to 24 in. of water, and the lagging were 'sniped' so as to be driven to the solid rock, and then nailed to the planking. The bottoms and sides of all puddling spaces were lined with burlap—after the crevices between the rock and lagging, below the troughs, had been calked with the same material. All rock was removed from the clay used in puddling, which was the most tenacious that could be found; it was put in dry (there being no lack of water where it was placed!) and was vigorously worked to an even consistence, and as thick as possible, mainly by tramping. This part of it was hard fast work, so as to stop the water as quickly as possible when once begun. The clay was sent down in gunny-sacks for convenience and quickness in placing it. A gate was made to fit the outlet of the troughs conveying water to the pumps, so as to divert all the water to one pump when necessary.

The puddling, and preparation for it, consumed 22 days, exclusive of delays; the labor cost was $851.75; the number of underground men varied from six to nine; wages per man, from $3.75 to $4.25 per day. The blacksmith and two hoist-men received $4 per day each. As the centre compartment was sunk, puddling and small troughs were put in 16 ft. below the first troughs to catch the splash and spray coming from high in the shaft, and to intercept the water should a leak develop in the puddling above.

The water was lifted from the lower troughs by an Edson diaphragm hand-pump. When the bottom was reached, in 23 days, there was still too much water for one 18-in. pump to handle, so a drift was run out 52 ft. toward the channel; this occupied 17½ days, by which time the water had decreased so that one pump could take it all. The men were then (February 5) put at work enlarging the sump to full size and raising in the shaft. On February 7 one shift distinguished itself by sending up 118 buckets of muck, and the other shifts did nearly as well about this time.

When the sump sets had been put in and lagged, a set nine feet higher was put in and lagged with five and six-inch poles. The bottom of the sump was then cleaned, and boxes for the pumps to stand in were placed by plumbing from the pump-bobs, and braced down to prevent floating. A tight platform was then put on top of the 9-ft. set, and raising continued under No. 1 pump. All the water was diverted to No. 2, and No. 1 was disconnected, overhauled, and made ready for lowering.

The rock was broken out under No. 1 on February 17, and the lowering of that pump and making the pump-column and spear-rod connections, etc., occupied seven shifts. With No. 1 taking all the water on the 6-ft. stroke, No. 2 was disconnected, overhauled, and made ready for lowering, and the men began taking out rock under No. 2, timbering as they raised. On March 2, No. 2 pump had been lowered, all connections made, the shaft timbered, and both pumps were working slowly on the 1-ft. stroke. The shaft-sinking and raising, and pump-work occupied 19 days exclusive of delays; the labor-cost was $2286.87. The labor of the whole job cost,

therefore, $3138.62. The cost of explosives, candles, timbers, lagging, and management, would give the total. The drilling was by hand, there being no machine-drill equipment.

One day while sinking was in progress a little dirty water was seen coming from one of the improvised sumps, and one shift of three men put in the shift finding and stopping the leak; with this exception the puddling stood as tight as a bottle, and the only water getting into the little trough was from the splash and spray from high in the shaft.

The men worked in undershirts during the latter part of the shaft-sinking, while driving the tunnel, and all the raising except breaking out.

The work described in the foregoing was designed and managed by Laurent Muller, at that time mine manager for the company mentioned. Considering the difficulties, and how they were met and mastered, it serves as an excellent example of how such work may be done.

RECOVERY OF COPPER FROM NITRATE SOLUTIONS.—Until recently the acid liquors containing nitrate of copper produced in etching the copper rollers used by calico printers have been allowed to run to waste. The recent high price of copper has induced the Calico Printers' Association of England to experiment on the possibility of recovering the copper from these solutions. The method which they have adopted consists in adding metallic lead or litharge to the solutions, so reducing the copper to metallic form and producing nitrate of lead, which is a commercial product of some value. In carrying out the process, the spent solutions, which vary from 1.3 to 1.4 sp. gr., are diluted with an equal volume of boiling water, and during vigorous stirring, lead or litharge is gradually added until no more will dissolve. The clear solution then contains nitrate of lead and copper. It is decanted and allowed to crystallize. The crystals so produced are re-dissolved by boiling in a saturated solution of lead nitrate obtained from a previous operation. The liquor is again allowed to crystallize, when crystals free from copper are obtained. A sheet of lead is then inserted in the liquor that has been used in cleansing the crystals in this way, and the copper is thus thrown down, leaving the solution available again for treating the next set of crystals. The mother liquor from the treatment of the acid with litharge contains nitrate of lead and copper. This is diluted to 1.275 sp. gr. and sheets of lead are inserted in it. After standing for some days all the copper will deposit on the lead. The clear liquor will contain nitrate and nitrite of lead.

PETROLEUM LOCATIONS ON PUBLIC LANDS.—At present petroleum locations are made under the placer law, but the Los Angeles Chamber of Mines desires that changes be made in this law as applied to petroleum claims. It recommends that 160 acres of land be considered a petroleum claim, and that only this amount of land be open to a single individual; drilling for oil is to begin within 90 days from the date of the location, and shall be diligently continued until a discovery of oil is made. Then application for a deed to the land under the present Government regulations shall be allowed. Another provision which the chamber desires adopted is that a prospector be permitted to pay $1 per acre rent on his holdings in place of doing actual development; this is to assure his right to the land for a period not exceeding one year. The intent of these recommendations is to render the prospector secure from having his territory usurped by homesteaders or mineral claimants before actual discovery of oil.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

A person located a placer claim, and subsequently received a patent for a lode claim, which was located so as to conflict with the placer claim. Thereafter he sold and conveyed by deed a portion of such lode claim, and the deed was held to convey so much of the placer claim as was within the part of the lode claim conveyed by the deed.

Collins *v.* McKay, (Mont.) 92 Pac. 295, Nov., '07.

Where the land intended to be conveyed by a deed to a part of a mining claim could be identified, it was held to be immaterial by what name the grantor described the property in the deed. And as between the parties to a deed to a part of a lode claim described by name, it was immaterial whether the location was a valid one as against others or not.

Collins *v.* McKay, (Mont.) 92 Pac. 295, Nov., '07.

Where a deed conveyed a portion of a mining claim, describing it by a particular name, the purpose of the name was to identify the property; and the presumption of law is that the grantor intended to pass the best title he had in the premises.

Collins *v.* McKay, (Mont.) 92 Pac. 295, Nov., '07.

The owner of a coal vein leased the same for mining for one year and as long thereafter as the lessee should continue to mine the same; the lessor was to receive 10 cents per ton for all coal mined, payable at the end of each 30 days; the mining to begin the next day. On failure to begin mining for two years and three months, it was held that equity would cancel the lease at the suit of the lessor.

Starn *v.* Huffman, (W. Va.) 59 Southeast. 179, Oct., '07.

The words "necessary to hold claims" in the statute providing that the certificate of location and of labor and improvement need not be sworn to, did not refer to "certificates of location," but only to the words "labor and improvements," which referred to the statute requiring the expenditure of $100 annually in labor and improvements in order to hold a mining claim prior to the issuance of patent.

Ford *v.* Campbell, (Nev.) 92 Pac. 206, Nov., '07.

A mining claim was located and the locator performed certain work which on survey was discovered to be on conflicting territory, whereupon the locator posted a re-location notice to the effect that such work had been abandoned. The first notice was not removed from the location monument, and the notice of re-location stated that the claim was re-located in order to better describe the place of the lode claim. These facts were held insufficient to indicate an abandonment of the rights under the prior location.

Ford *v.* Campbell, (Nev.) 92 Pac. 205, Nov., '07.

The senior location was held to take the entire width of the vein on its dip, where the apex of such vein was partly within two or more adjacent lode mining claims.

Lawson *v.* United States Co., 28 Superior Court Reporter 15, Oct., '07.

In mining leases, giving the lessor a share of the product or a tonnage of ore or other product, even where there is no covenant to begin work within a certain time, there is an implied covenant to begin in a reasonable time, because the consideration in contemplation of both parties otherwise fails. This rule prevails where no time is fixed in the lease for the work to begin, where it appears from the lease that time was the essence of the contract; and under the further rule that in such contracts where no time is expressed, the law implies a promise to perform within a reasonable time.

Mining in Panama.

Written for the MINING AND SCIENTIFIC PRESS
By SCOTT TURNER.

Some mining has probably been carried on in Panama, in a desultory fashion, for over 300 years. Traditions of early production and remains of old workings lead to the belief that at one time a substantial amount of gold was produced, almost entirely by placer mining, during the era of Spanish occupation. At present there is but little activity in mining anywhere in the Republic, the one important property being the well known Darien mine at Cana, 150 miles to the south and east of the city of Panama. This was an *antigua*, re-discovered after a good deal of prospecting; the ore ran well in the upper levels, but is becoming poor with depth, which has led to the use of the caving system of mining, in place of square-setting. There is practically no placer work being done in Panama at this time, although several schemes for dredging have been considered.

Manganese mines on the Atlantic coast produced some ore for shipment to the States, but they have been closed down for several years. These mines were developed by American capital, but became unprofitable. Mining companies have been organized to exploit properties at various points along the present Canal Zone, but they have been failures. The same may be said of the districts west and north of the city of Panama. During the past ten years, four or five attempts have been made by American organizations to operate properties in the province of Veraguas, and while this district has thus far proved disappointing, it is perhaps the most promising place to prospect in the Republic, although that is not claiming much for it.

To reach this district, it is necessary to travel by coasting steamer to Aguadulce or Sona, thence overland to Santiago. The distance from the city of Panama to Aguadulce is about 90 miles, including a six-mile trip up a narrow estuary to the new Government dock that lies about three miles from Aguadulce and Pocri, in the province of Coclé. Three years ago the trip into the interior from this point was an unpleasant one, starting with disembarkation from the steamer into a muddy salt marsh, through which it was necessary to wade, often waist-deep, for a couple of miles. But since the payment by the United States of $10,000,000 for the Canal Zone strip, a good deal of money has been spent—much of it foolishly—in the improvement of highways into the interior, so that now a wide roadway has been built to the water-front, and a straight and level road leads through a flat open country for 12 miles to the Santa Maria river, a swift stream about 250 ft. wide, over which General Jeffries, a professional soldier of fortune, has recently completed a steel-girder bridge. With the exception of some *caliche*, the prevailing soil is red clay, the result of the weathering of the andesite country, which is the principal rock. Some small patches of limestone are reported along the coast, but for over 100 miles, with the exception of a small fossil-bearing bed of sandy shale near Santiago, nothing is to be seen but a vivid red clay; black sand glistens in every gully and ravine. To the left, on the peninsula to the east of Montijo bay, the Boston-Panama company owns 500 square miles of ground on which it is doing some prospecting in a crude way, in the region about Pesé and Los Minas. There is a small company operating near Los Santos.

Numerous streams have to be crossed by ford or ferry, and across the Kanaka river is a novel swinging bridge, the passage of which causes a little flurry among the sluggish pack-horses. This trip from Aguadulce to Santiago is made once each week by ox-cart freighting caravans, but in the wet season transportation of this kind is extremely unreliable, and a pack-train is more expeditious.

Santiago is the terminus of the regular mail service and of the Government telegraph line. It is connected by trail with the ports of Montijo, Sona, and Puerto Mutis, but the Aguadulce route is the most traveled. From Santiago to Cañazas, the country is more broken, as the foothills of the main mountain range that forms the backbone of the country are here encountered. A cart-road, branching to the right a few miles beyond Santiago, leads to the Remance mines, owned by a corporation financed in Scotland. This company has operated for 20 years, developing and stoping a six-foot vein standing nearly vertical. The ore is a hard vitreous quartz, filling a probable fissure in an andesite country, and averages about $7 per ton. The mine has never been a dividend-payer. Stamp-milling was tried, but discarded in favor of dry crushing and cyaniding. The mill has a capacity of 50 tons per day, but the mine is seldom able to supply this amount. The frame of the mill-building is steel; the crushing is done by a jaw-crusher and two sets of rolls; the extraction is about 75%. Half a dozen white men are employed, the underground work being done by native laborers on the contract system. The supply of labor is quite irregular, and frequent shut-downs of two or three months, waiting for roll-shells or other supplies, would seem to indicate rather lax management.

Cañazas, a native village of 400 inhabitants, is situated at an altitude of about 800 ft., and may be considered the centre of the recent mining activity in Veraguas. Five miles to the southeast, at a property known as La Guaca, stand the remains of an old 20-stamp mill, the mortars bearing the name of the Pacific Iron Works. A concrete dam collected water to run the water-wheel, and an old engine and boiler show that auxiliary power was necessary during the dry season. This mine was originally located in 1833, but not worked much until the early 'eighties, when an *arrastre* was constructed. In 1887 a company was formed in New York City to operate the property, and a mill was ordered from San Francisco. Louis Janin Jr. had charge of the mill, which only ran a few weeks. The vein is a flat impregnation zone, slightly rolling, between andesite walls. On the foot-wall is a streak of hard, iron-stained quartz; above this, the silicification decreases and the ore grades gradually into the barren overlying porphyry, the pay-streak averaging about three feet wide, the amount of iron stain being indicative of the degree of silicification and the amount of gold. Several thousand feet of work still stand open, and a good deal of ground was stoped, all operations being carried on through adits. Samples from the old stope-walls gave assays varying from $1 to $65. No work has been done on the property since 1894.

Two miles west of Cañazas, the Detroit-Panama company started operations about three years ago. This company cut a wagon-road from Santiago, brought in an engine and boiler, and some new inventions in the way of coarse and fine crushers and amalgamating devices; as the work was done without reliable technical advice or direction, the mill only ran a short time. The company was floated on the strength of a report of a large deposit of $15 ore, but careful sampling after the mill had been built revealed nothing richer than $2.50, so the project was abandoned. The gold occurs in seams in a jointed andesite, and apparently there is a mountain of low-grade material. While old prospectors had been able to clean up a little bullion by running a diminutive three-stamp mill on ore secured by 'candle-stick mining,' it is

impossible to stope anything rich enough to treat on a large scale.

The district to the north of Cañazas, marked by the two peaks of Viriguas that rise to an altitude of about 3500 ft. and are visible for a radius of 20 or 30 miles, is perhaps the most interesting region in Panama, not as much from any chance of successful mining in the future as from the evidence of work that has been done there in days gone by. Viriguas is about 30 miles from Cañazas, over extremely rough trails, and three good-sized rivers, the Cañazas, Piedra, and San Pablo, must be crossed, together with many smaller streams. This is easy enough during the dry season, which lasts from December to May, but during the rainy season the trip is hazardous. The streams all have their sources in the main Cordilleran range, whose peaks are forever enshrouded in clouds. A heavy rainstorm in the mountains, of which the traveler may know nothing, in a few hours will cause a quiet peaceful stream to become a roaring raging torrent. If the traveler is caught between two streams, he must sit down and smoke, curbing his impatience for perhaps a few hours, perhaps several days, until the water subsides. In the beds of these streams are rounded boulders of granite, brought by floods from the granite core that forms the backbone of the main range. Granite and andesite are the only rocks encountered. The country is steeply rolling, cut with heavily-timbered steep-sided ravines, the ridges being barren of tree or shrub, but covered with long grass that affords excellent grazing for the long-horned sleek cattle that roam at will over the ranges. The export of beef is the only industry that the country has. Once or twice each year the herds are rounded up, driven to some port, and shipped to Panama.

Test-Pits in the Bed of Corutu Creek.

A Prospector's Camp. West Viriguas Creek in the Background.

Open-Cut on Viriguas Peak.

A Ford on San Pablo River.

On the more northerly of the twin Viriguas peaks, the remains of an elaborate system of ditches and reservoirs are visible, and at several points open-cuts and pits show where a good deal of ground was sluiced. Work of this sort was done years ago, all the way from the upper portion of the north side of the peak, to the San Pablo, Tolerica, and Viriguas rivers, which lie about 1500 ft. lower and three or four miles distant. The gravel in the beds

of two creeks, Corutu and Limon, which have their sources on the peak, have been worked for nearly their entire length. Between these two streams and around the peak, the ridges have been worked in spots. The material here, however, is of rather peculiar character, being a stiff, iron-stained, residual clay, and not gravel at all. The method universally employed by the original operators was ground-sluicing, probably through bedrock sluices, most of the ground being so stiff as to necessitate breaking with a pick. As a result, there are large cuts standing open, with their sides often 50 or 60 ft. high and nearly vertical. Nearly all this clay shows some gold in the pan, but not enough to encourage mining on a commercial scale. Along the banks of the streams, small hand *arrastres*, made from granite boulders, are to be seen; they were probably used in cleaning up the black sand.

Within the past five years, two companies have been formed in Michigan to work this placer ground, and to develop a quartz vein at the head of Corutu creek. As is often the case, the directors had the mistaken impression that ground that could not be profitably worked a century ago could be made to pay with modern methods. They neglected to consider that work was formerly done by enslaved natives, the labor costing nothing, and the old methods for this kind of placer work were every bit as efficient as any that could now be applied. Test-pitting and prospecting with open-cuts and a tunnel proved the supposed quartz vein to be an irregular lens of granular chert, lying in andesite, that averaged $1.30 per ton in gold, and all work was abandoned. Several foreign companies have prospected in this region, and, while some traces of copper, lead, and zinc are to be found, nothing of importance has as yet been unearthed.

Three possible sources of the placer gold are apparent. The andesite in the vicinity of the peaks always carries some finely disseminated pyrite, which undergoes surface concentration on a rather rapid scale, as the igneous rock carries no quartz whatever, and weathers easily. Another possible source of gold is the small seams with calcite, quartz, and zeolite minerals, which are sometimes found in the andesite; and occasionally small irregular veins of quartz are found in the unaltered country, all carrying traces of gold.

The petrographic features of the Viriguas district, and, as I have said before, of this whole part of the Republic, are extremely simple. There is but one rock of wide occurrence, and that is an augite-andesite, showing typically as a hard, compact, crystalline rock of blue color and porphyritic texture, with phenocrysts of striated plagioclase feldspar, no quartz, some augite, and always some pyrite. This typical rock grades in alteration phases, through the intermediate stages of green and hard, then gray and soft, spheroidal boulder forms, then a soft red rock still showing a porphyritic texture, to the ultimate stage of the decomposition of all the feldspars and the oxidation of most of the iron, making a deep-red, soft, and talcose rock, with the original texture almost unrecognizable. Some few modifications of this typical rock occur, such as an occasional amygdaloidal form of what is probably a more basic phase, the amygdules being filled with quartz or some hydrous silicate, usually a zeolite. Also, rarely the more acid phase occurs in limited areas, possibly approaching a dacite. One of the most common forms of andesitic weathering is in rounded boulders, of a green color. The surface of these boulders is dark; they show concentric weathering, with shell-like layers, looking, as they lie scattered about, not unlike the concentric basalt bombs of volcanic origin found in the Cinder Buttes region of Idaho. These masses weather out at the surface, or even lie imbedded in the residual clay.

This lithological sameness gives rise to a topographical monotony throughout the entire region, there being no sedimentaries, intrusives, or extrusives to modify the landscape by their differential weathering. Across the broad trunk valleys, and for a radius of 30 miles from an observation point on an exposed peak, the topographic features are seen to be everywhere the same.

Labor, throughout the Veraguas province, is scarce and inefficient. The standard of living is so low that the native has no use for money. The inhabitants are ignorant, speaking broken Spanish, and are indifferent workers. A wheelbarrow is an unsolvable mystery to them, and they gingerly attack a muck-pile with a shovel with about the same motion that a billiard player uses in making a massé shot. Twenty-five cents per day, without board, is the standard wage, and it would be impossible to carry a payroll of any size, as the population in the mountains does not exceed five men to the square mile, with no villages near-by. However, workmen often come as far as 25 miles and work a few days, or at most two or three weeks, to get a little money with which to purchase a new *machete* or a few gallons of *aguardiente*. Considered as a whole, the Republic of Panama does not offer a very attractive field for the prospector or the promoter. Many tales may be heard concerning the richness of spots in inaccessible regions and there is popularly supposed to be rich dirt at the headwaters of the Chagres river, but most of these points have been prospected at one time and another by intelligent prospectors, who deny that any rich fields have been overlooked.

ASSAY OF MERCURY ORE.—The following method of assaying mercury ore is given by Holloway in the *Analyst:* Mix the ore in a crucible with 10 gm. of iron filings, through 60 mesh, and cover with 5 gm. of iron filings through 30 mesh. Set the crucible in a hole in a tin plate or asbestos board in such a way that the bottom of the crucible may be heated by the flame, while the top remains cool. Cover the crucible with two pieces of clean silver foil which have been weighed, and which are of unequal size, the upper piece being the larger. Set on top of the silver covers a copper or metal vessel through which cold water may be passed in order to keep the plates cool. Heat for 20 min., allowing only the bottom of the crucible to become red hot. Cool the crucible, dry, and weigh the covers. If tarry substances appear on the foil, they may be rinsed off with alcohol before drying. The amount of ore to be taken for assay depends upon its richness. For less than 1% of mercury use 2 gm.; between 1 and 2% mercury, use 1 gm., and so on.

GOLD IN ALASKA.—Although gold is universally distributed along the coastal mountains of southeastern Alaska in lodes, and less commonly in placer deposits, there are relatively few localities which show a sufficient concentration of auriferous minerals to make valuable ore-bodies; in these few places the ore is usually low-grade. The possibility of mining such ores, however, is obvious when one considers the available water-power and the favorable means of transportation that the country affords. In the gold-quartz veins or lodes, the gold is found both in the native state and also combined with metallic sulphides, which usually penetrate into the inclosing country rock. These quartz-filled fissures were formed subsequent to the general metamorphism of the coastal mountain range and after the intrusion of the granodiorite; their content is in genetic relation to the intrusive rock.—Alfred H. Brooks.

Progress in Southeastern Alaska.

Mining development in southeastern Alaska during 1907 has been greatest in the Ketchikan district, where several copper mines on Prince of Wales island are being exploited, says Mr. C. W. Wright, of the United States Geological Survey, who has recently returned from Alaska. Mining was actively advanced on this island in the spring and early summer, and considerable low-grade ore was produced each month, but most of the mines suspended operations in September and October, with the fall in the price of copper, and the expected increase in the copper production for 1907 will not be realized. Many of the mines that were forced to discontinue operations were in good condition for profitable production at the time they closed, and at some it was not the price of copper alone that caused suspension, but unfavorable conditions as to labor and transportation.

The copper occurs in the form of chalcopyrite, either in irregular masses associated with magnetite, garnet, and epidote at the contact of intrusive rocks with limestone, as at the Mamie, Mount Andrew, and Jumbo mines, or in the form of lenticular bodies associated with pyrite, quartz, and calcite along shear zones in the slates and greenstones, as at the Niblack and other mines. Developments at the Mamie mine disclosed new orebodies on the lowest level, and considerable ore was ready for extraction in the upper levels at the time operations closed. A similar condition existed at the Mount Andrew mine, where large ore reserves were being developed and plans for more extensive operations had been made. At the Rush & Brown mine the copper deposits were being explored 100 ft. below the present working level, which is 90 ft. in depth, and the results were encouraging. Though the developments at the Jumbo mine and Niblack mine are still being advanced and good orebodies are being opened, shipments have been temporarily suspended. Work has been discontinued for the winter at most of the prospects which gave promise of becoming copper producers.

In the Juneau mining district, to the north, where gold is the predominating metal, there has been a steady advance in mine development. At the Treadwell group, on Douglas island, the use of oil instead of coal has been introduced for the steam-plants, and the capacity of the water-power plants has been increased, thus materially reducing the cost for power. The gold production for 1907 from these mines was less than in 1906. This decrease is attributed to the inefficiency of labor, a condition which has affected the entire region. At the Perseverance mine a 100-stamp mill has been completed and 50 stamps have been in operation most of the summer. Work at the Alaska-Juneau mine was continued from June until November and results similar to those in former years were attained. The Ebner mine suspended operations early in June and the mine has been idle since that time. Some exploratory work was done at Sheep Creek, but no actual mining. At the Eagle River mine developments have been vigorously advanced in search of the main vein, which is displaced by a fault. The developments now show both the character and the amount of this comparatively wide zone of faulting, and the vein is being developed at points further in the mountain, beyond the fault. Considerable interest has been shown in the prospects north of Eagle River, at Yankee Basin and at the head of Cowee creek, where auriferous quartz veins are being explored. The Jualin mine, which was being operated under a lease during the summer, was the only mine in the Berners Bay region where mining was in progress. Except a limited amount of prospecting and small scale operations at the Crystal mine, near Snettisham, no work was done in the mines south of Juneau.

In the Sitka district the only active mining operations during the year have been at the DeGroff mine. At this mine a 4-stamp mill was installed to treat the ore from a gold-quartz vein and some gold was produced.

The Shipment of Supplies and Freight by Rail.

When property is delivered to a railroad company or other common carrier for transportation, the carrier must transport it to its destination with reasonable dispatch at the agreed or published rate, and deliver it to the consignee in the same condition as that in which it was received. If it fails to do so, the carrier must pay the owner, if lost, or compensate him for damage, if any is done. Nevertheless the consignee is generally anxious to receive the goods, and in order that he may do so, the shipper should take certain precautions to ensure correct transmission. And, first, he should see that the property is properly crated to stand transportation, and clearly marked with the name of the consignee and the destination. Next, he should make out (preferably in triplicate on a shipping receipt of the road by which the goods are to go) the name and address of the shipper, the name and destination of the goods, the number of packages or pieces and their weight, and note that they are in good condition when delivered. When the freight agent takes over the property he signs the receipt, which is in evidence of a contract, and, like a note, is good for the property it calls for. It is well to see that the agent checks these quantities and notes the condition of the shipment. In case the goods, as ore, grain, etc., are shipped in carload lots, the shipper before loading should examine the interior of the car, if necessary cover with pieces of board any holes by which the ore may leak out, and, after loading, see, if possible if the doors are locked and sealed by the agent. The shipper should also tack to the car at opposite corners printed cards showing the name of the shipper, the name of the consignee, the destination of the car, and its number. In case freight is wrongly way-billed by the agent, this will serve to correct, or at least to call attention to the error. Through carelessness, thoughtlessness, or ignorance the following mistakes can be made by the agent of the railroad company:

A. Receipting for more freight than has been actually received, or receipting for it as in good condition, when in fact it is in bad order.

B. Way-billing freight to a wrong consignee or destination.

C. Loading freight in one car and way-billing in another.

D. Failure to see that all packages are marked with the name of the consignee or destination.

E. Transferring freight carelessly.

F. Improper loading and crating of freight, and rough handling of the cars when switching.

G. Delivering freight to the wrong person, or without an order from the consignee.

H. Delivering freight to a party who is to receive it, and who has failed to present an order from the party to whom it is consigned.

At the Cariboo hydraulic mine, situated at Bullion in British Columbia, the men work close to the overhanging face of the bank, from which large masses frequently fall, but one of their number is detailed as a lookout; so expert has he become in judging the condition of the face of gravel that ample time is given the men in which to seek protection.

Ore Testing at Salt Lake.

Written for the MINING AND SCIENTIFIC PRESS
By ERNEST GAYFORD.

The testing plant of the General Engineering Co. at Salt Lake City, Utah, is in many respects the most complete and up-to-date establishment of its kind in existence. Although it has only been in active operation a little over a year, it has already been instrumental in solving several metallurgical problems, thus saving thousands of dollars, as compared to attempts to solve similar difficulties in the mill itself.

From the accompanying illustration it will be seen that the main plant is so arranged that tests in carload quantities can be made by any one of the following processes, or by combination of any or all of them:

Amalgamation. (Plates and Pierce amalgamator.)

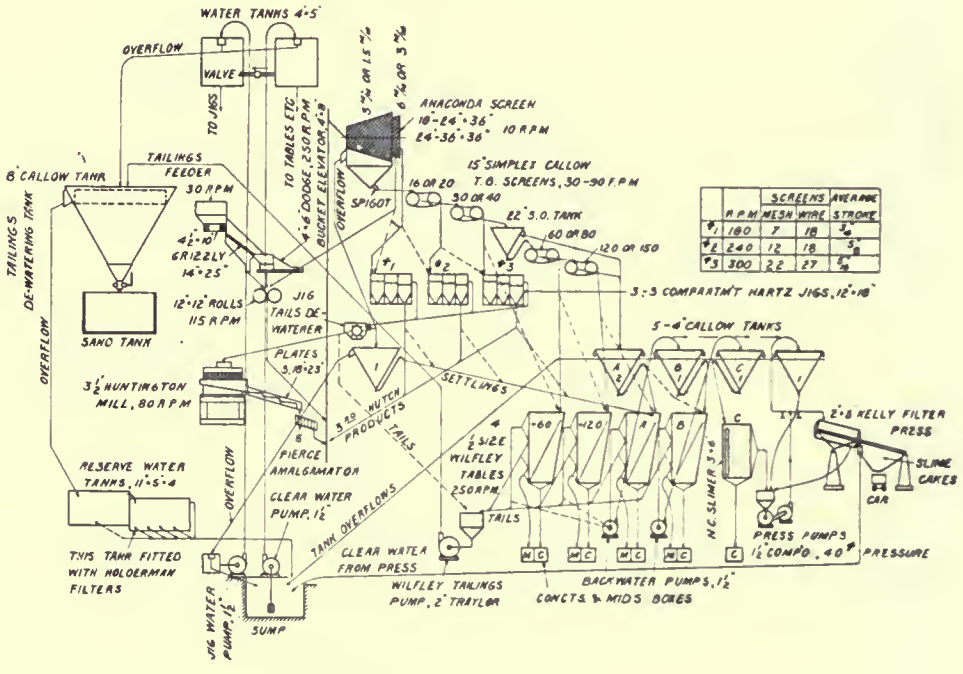
Water concentration. (Jigs and tables.)

Magnetic separation. (Ding's or Wetherill's.)

Cyanidation. (Sand and slime treatment in conjunction with filter-pressing.)

Besides the main plant, which is equipped to handle ore in 10-ton lots, a miniature plant has been installed where all these methods can be adapted to smaller tests of a few hundred pounds each.

From the flow-sheet, it will be seen that in designing the plant J. M. Callow, the president of the company, has carefully borne in mind the need for elasticity in a testing plant, and that products from the different machines can be diverted, by a change of launders or spouting, to their correct destination.



After the material to be treated is once in the feeder at the head of the Dodge crusher it is handled mechanically throughout the whole plant, and no hand-feed, with its inherent errors, is resorted to. The floors, piping, and launders are so arranged that during the operation of a test nothing can escape, all waste material finding its way by gravity either to the sumps or tailing-pump; it is possible thus to account for every pound of feed that has been used, and to ascertain, by actual weights, the proportions of different products into which the ore has been divided.

In the installation of every machine care was taken by the designer that, wherever necessary, accurate time samples could be taken; this is chiefly accomplished by a swinging pipe or launder and a stop-watch; in this way not only can reliable pulp samples be obtained, but also, where wet crushing is employed, the correct proportion of water can be determined, which is one of the most important factors in ore dressing.

The General Engineering Co. recommends that the carload of test ore should be first sent to a public sampler; this allows not only of a thorough mixing of the material, but also enables an average sample of about 500 lb. to be sacked separately and marked at the sampler. The sampler otherwise handles the car in a manner similar to that pursued had it (the car) been sent them for sale on the open market, a head sample being sent to the shipper, one to the ore-testing plant, and one reserved for reference.

Previous to starting operations in the main testing plant, a series of tests are made in the miniature plant, on the 500 lb. that the sampler has sacked separately, the ore being treated by any number of different methods that its physical nature justifies, accurate weights and samples being taken, results systematically recorded, and comparisons made, with the idea of ascertaining the best metallurgical process for the ore in question, care being taken to give due weight to local conditions at the mine; in other words, the idea is to choose the particular treatment that will yield the highest net returns.

After a careful comparison of the results from the preliminary tests the main plant is adjusted to suit the method chosen and the carload is run through. It is of interest to state that the results from the preliminary tests check closely with those obtained from the carload test, 5% being an extreme variation; this is due to the fact that even in the miniature plant, in which the preliminary work is done, the plate, table, or jig is fed mechanically and not by hand.

The best result in milling does not necessarily mean the highest extraction. Supposing the preliminary work on a carload of test ore showed that by amalgamation, concentration, and cyanidation a 95% extraction could be obtained, but by amalgamation and cyanidation alone only a 90%. The point then to be decided is whether the extra 5% obtained by concentration is going to cost more than it is worth, and if the expense of converting the concentrate into money is going to exceed the yield from such extra extraction. The grade of the ore, local conditions at the mine, and good judgment are the factors employed in reaching a decision.

Again, supposing the ore in question is purely a concentrating ore, the points to be threshed out in the preliminary work would be the initial crushing, where to start jigging and where tabling, what products need recrushing or re-treatment, whether final products be made by gravity methods, or whether a magnetic or chemical process is required before a finished product is made. Here, also, the commercial question comes in; if an 80% saving can be made and a rejection made at each jig, it may be better than an 85% extraction, obtained at the

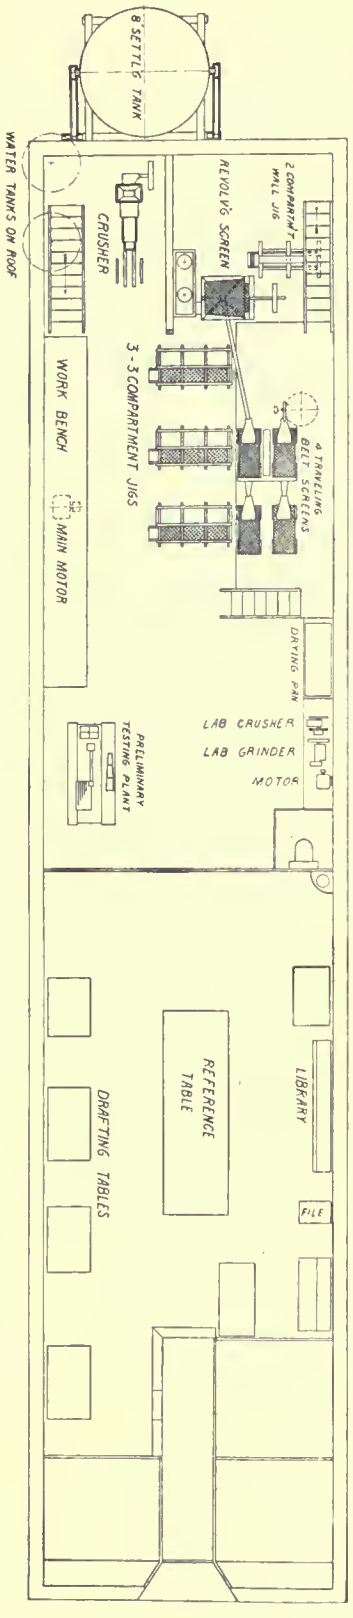
expense of re-crushing all the jig tailing instead of a small quantity of jig middling. Further, conditions at the mine may call for a high-grade concentrate and a high ratio of concentration, and while this may have to be obtained at the cost of a small loss in the tailing, the process must not only fit the ore but also the mine from which the ore is taken.



The report sheets employed by the General Engineering Co. (a sample of which is shown in the accompanying cut), while elaborate, are concise, inclusive, and easy for the lay mind to understand, they show the saving of the different minerals at each stage of treatment, the proportion that each saving bears to the total amount of that mineral in the head sample, and finally a number of different combinations are worked back to the actual net returns.

The question is often asked whether results in a testing plant can be duplicated in a mill. Yes, provided the sample on which the test work was done is representative of the ore that will be sent to the mill, that the design of the mill incorporates the system that was found most applicable to the ore in the test, and that when the mill goes into operation it is in charge of some one familiar, at least, with the fundamental principles of ore treatment.

A well-known mining engineer remarked to the writer recently that it was extraordinary, but nevertheless a fact, that no man would think of buying a suit of clothes without first taking the precaution to fit them on, but that the same man might not hesitate to place an order for machinery for a $50,000 mill, and be surprised when it went into operation that it did not fit the ore it was built to treat.

REMARKS

THE GENERAL ENGINEERING CO

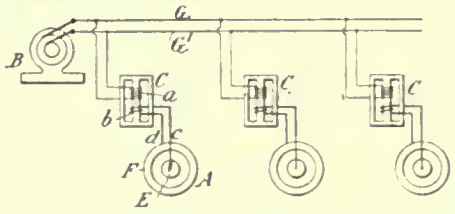
By J. H. Callow

Assays of sea dredgings indicate that the bed of the Atlantic ocean carries appreciable amounts of gold and silver, and that the deep-sea bottom is relatively richer in gold than that nearer the shore-line.

MINING AND METALLURGICAL PATENTS.

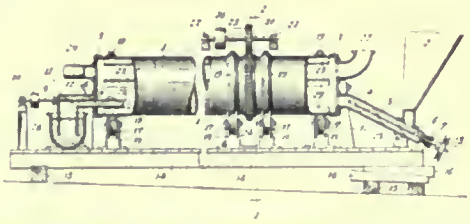
Specially Reported for the MINING AND SCIENTIFIC PRESS.

ART OF ELECTRIC SMELTING.—No. 874,944; Frank Creelman, New York, N. Y.; assignor to The Willson Carbide Works Company of St. Catherines, Limited, St. Catherines, Canada, a Corporation.



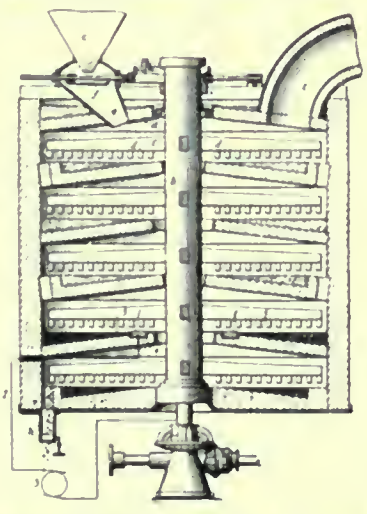
The process of electric smelting which consists in subjecting the material to be smelted to the heat of an electric current of substantially uniform amperage notwithstanding variations in the internal resistance of the furnace, and regulating the furnace to restore the normal internal voltage and maintain an approximately uniform expenditure of energy.

PROCESS FOR TREATING SMELTER SMOKE AND EXTRACTING VALUES FROM ORES OR METALLURGICAL WASTE PRODUCTS.—No. 875,222; Stanley S. Sorensen and George C. Westby, Murray, Utah.



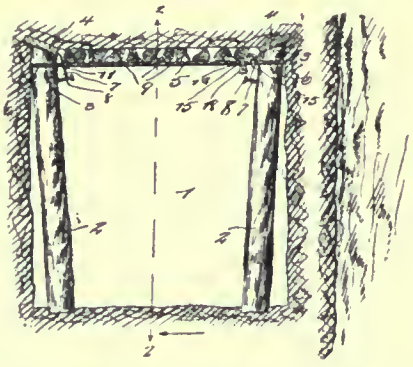
The hereinbefore described process of purifying smelter smoke and extracting values from ores or metallurgical waste products consisting in preparing the materials to be treated by comminuting the same, and then causing sulphurous smoke to come in contact with the materials in the presence of moisture or water while they are being agitated, whereby the valuable bases or metals of the slag are converted into sulphates, thionates, thionites, and sulphites by means of the sulphur dioxides and sulphuric acid of the smoke.

FURNACE FOR DESULPHURIZING AND AGGLOMERATING ORES.—No. 875,331; Andrew J. Dull, Harrisburg, and Joseph Weatherby, Jr., New Cumberland, Pa.; said Weatherby assignor to said Dull.



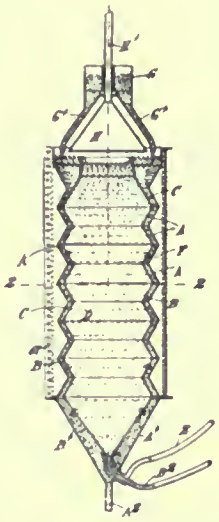
An ore roasting furnace having means for heating the ore to desulphurize the same, an electrode arranged in the furnace, a second movable electrode co-operating with the first-mentioned electrode to produce an electric arc to the action of which the heated ore is subjected, said movable electrode being adapted to move the agglomerated ore beyond the radius of action of the arc

MINE-ROOF SUPPORT.—No. 875,182; Frederick C. Keighley, Uniontown, Pennsylvania.



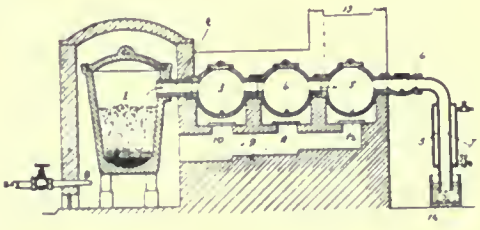
In a roof support for mines, a plurality of standards arranged in opposite rows, timber-supporting means connecting opposite standards, and wedges to prevent downward displacement of said means. In a roof support for mines, a plurality of standards arranged in opposite rows, timber-supporting tie rods or stretchers connecting opposite standards, and wedges to prevent downward displacement of said tie rods or stretchers.

PROCESS FOR THE TREATMENT OF ZINCIFEROUS ORES AND METALLURGICAL PRODUCTS.—No. 875,424; James H. Gillies, Auburn, Victoria, Australia.



An improved process for the treatment of zinciferous ores and metallurgical products consisting essentially of first roasting the ore, second feeding such roasted ore through a current of dilute sulphuric acid moving continuously in an opposite direction, and finally, continuously separating the solution of zinc sulphate from the slimes and undissolved particles by settlement, substantially as described.

PROCESS OF TREATING COMPLEX ORES CONTAINING ZINC AND OTHER VOLATILIZABLE METALS.—No. 875,381; George M. Rice, Worcester, Massachusetts.



In the art of reducing complex zinc ores direct from the raw ore, the process step which consists in supplying to the ore a quantity of finely divided metallic iron in large excess of the amount required to combine with the sulphur from the volatilizable metals in forming monosulphide of iron (FeS) and an additional amount sufficient to form slag, with the silica contained in the ore during the melting operation

Mineral Resources of the United States.

The twenty-third annual volume of the series 'Mineral Resources of the United States,' published by the United States Geological Survey, is now passing through the press. This volume contains a statement of the production of mineral substances during 1906.

Practically the same form of arrangement has been preserved in all of the 22 preceding volumes of the series, and it has become so familiar to the mining fraternity as to render any description unnecessary. But for those to whom this volume comes as a new book of reference it may be explained that the book is divided into chapters, each of which treats of a separate mining industry. The student who consults this report to find a combined statement of the mineral resources of a given State is referred to the tabular statement of output by States in the summary, and to the index, in which, under each State, is a list of the minerals produced therein. The effort is also made to show the conditions of the domestic industry in relation to foreign conditions in the same mineral industry.

It is important, also, for the new reader to know that this volume is simply the consolidation of the separate chapters after they have been published in pamphlet form, frequently months in advance, and that these pamphlet reports, and not the final volume, mark the dates at which the reviews become available. Further, for greater statistical promptness, it is the custom of the Survey to give the principal figures to the public press in advance of the publication of the chapters in pamphlet form.

Several new names appear as the responsible authorities in charge of individual chapters. This is in pursuance of the policy of the Geological Survey announced in the volume for 1905 of assigning all subjects to members of the Survey staff who, in this work and in allied problems, are employed solely in the Government service. The report on iron ores for 1906 was prepared by Edwin C. Eckel, who, in past years, has made a special study of the iron ores of the South. The series of iron ore reports for the United States owes its statistical development entirely to John Birkinbine, of Philadelphia. Under his direction the statistics of iron ore production have been developed to an exceptionally high degree of accuracy. This has been due, fundamentally, to the great confidence given him by iron ore producers, among whom Mr. Birkinbine has developed a spirit of fraternity similar to that which James M. Swank, the general manager of the American Iron & Steel Association, has evoked among the iron and steel manufacturers. The reports on copper, lead, and zinc in preceding years have likewise been developed entirely by Charles Kirchhoff, of *The Iron Age*, New York. These reports have become classic for their statistical accuracy and for their keen and fair analysis of the trade situation. The report on copper for 1906 was made by L. C. Graton, and those on lead and zinc by J. M. Boutwell.

This volume also records the change of the administrative head of the division of Mining and Mineral Resources from David T. Day to Edward W. Parker, Dr. Day devoting his time to the important work of preparing the reports on petroleum and natural gas. The change of administration includes the placing of the statistics of metal production (except iron ores) under the supervision of Waldemar Lindgren, who has, as chief assistants, Charles G. Yale, of San Francisco, Victor C. Heikes, of Salt Lake City, Chester Naramore, of Denver, and Messrs. Boutwell, Graton, McCaskey, and Siebenthal, of Washington. This arrangement has materially strengthened the work of the division. It is designed, also, to supplement the statistical data with the results of geological and chemical research in so far as they pertain to the economic development of our mineral resources. The division of Mining and Mineral Resources has been for some time an integral part of the geologic branch of the Survey, this incorporation having been accomplished when the present plan of organization was adopted.

By way of brief review and summary of the series, it may be said that in the 27 years covered by these 23 reports, the scope of the work has remained practically the same—an annual review of the mineral production of the United States, and of the state of knowledge of the mineral deposits from which the products come. But the work involved has multiplied in two directions. In the beginning the statistical feature of the work was satisfied by an estimate as to the total output of each useful mineral. This estimate was based upon the best commercial estimates available, and the statistical correspondence was limited to a few hundred letters each year. When the control of the work passed into the hands of Dr. Day, he took it with the intention of developing each statistical inquiry from an estimate into an accurate annual census through confidential reports at first hand, as rapidly as facilities would permit. This result has now been achieved with every industry except petroleum, and to this particular and difficult task he will henceforth limit his work. The correspondence necessary for this annual census of the mines of the United States has grown from a few hundred letters to an average of three written or printed communications a year to every known mine operator of the United States, more than 150,000 in all. In order to make such correspondence successful, it has been necessary to send agents to the mines themselves, both for scrutiny of the statistical returns and in order to acquaint the operators with the nature of this inquiry, and thus to secure the co-operation essential to success.

This growth of statistical work would have been necessary even if the mine development had remained stationary. Instead, the rate of increase has been far beyond all reasonable prophecy. In the 27 years from 1880 to 1906, inclusive, the value of the mineral output of the United States has increased over five times. This marvelous growth is of additional interest in that it shows approximately by its fluctuations the financial ebb and flow of the whole country. From $364,928,298 in 1880, the value has risen gradually to the immense sum of $1,902,517,565 in 1906. This is the value of the mineral products in their first marketable condition, as shown in the first large tabular statement of the summary, where all unnecessary duplication is excluded.

It is of interest to note in passing that Pennsylvania produced nearly $600,000,000, or about 30% of the total value of the output of 1906; Ohio about $200,000,000, or 11%; Illinois, $117,000,000, or 6%; New York and West Virginia, $81,000,000, or 4% each; Montana, Colorado, and Michigan, 3.5% each; Arizona and Missouri, 3% each; Alabama and California, 2.5% each. The value of the mineral output of each of the twelve States named was in excess of $50,000,000. If the combined value of output of 11 of these States ($905,000,000) be deducted from the total ($1,902,000,000), the value of output of the twelfth State, Pennsylvania ($583,000,000), exceeds the combined value of output of all the remaining States of the United States by more than $150,000,000. Keeping pace with this growth has been a strain, and it is gratifying that the system has so expanded that the statistics of this wonderful production continually increase in completeness and accuracy. This attainment is largely the result of the hearty co-operation of the producers, due to their faith in the Survey.

In carrying out the plan of co-operation with the other divisions of the geologic branch, a twofold advantage is secured. It brings to the statistical work on the one hand a corps of trained men whose field observations have developed a keen appreciation of the geologic and economic importance of each mineral product. This has been particularly illustrated in the reports made by Mr. Lindgren and other mining geologists on gold and silver in the volume for 1905, and the reports on the same subjects and also on copper, lead, zinc, and quicksilver in the present volume. On the other hand, the mining geologists have obtained and will continue to derive from their statistical work an insight into the industrial and commercial conditions which so largely affect the demand for the different minerals, and lead to the search for, and development of, the mineral deposits with the geological relations of which their field work makes them acquainted. The bringing together of these two classes of study of our mineral resources, that of their geology and manner of occurrence, and that of their statistics and economic conditions, is to be one of the special features of the future work of this division.

MINING AND SCIENTIFIC PRESS

Editorial.

ON ANOTHER PAGE we publish a letter from Mr. Claude Sachs, editor of *The Mining Investor*, criticizing a recent article by Mr. J. H. Curle. It is well that the other side of the case should be stated and while we disagree with the opinions expressed by Mr. Sachs, we appreciate his courtesy in contributing to our columns, and leave Mr. Curle to submit a rebuttal.

MANY of those who read the President's dispatches to the Governor of Nevada will have remarked on their peremptory and rather rough tone: this seemed to be contrary to diplomatic usage. The explanation is: the President knew the Chief Executive of the Sovereign State of Nevada was carrying a load in excess of the factor of safety usually allowed in good engineering practice.

IT IS ESTIMATED that the mines of the Lake Superior region produced 223,800,000 pounds of copper in 1907, as against 228,400,000 pounds the year before. Calumet & Hecla produced about 84,000,000 pounds. Osceola and Tamarack decreased their production, and were the main factors in making the total less than that of 1906. But this is not due to any marked curtailment of output after the price of copper declined toward the close of the year, for it is characteristic of the Lake Superior companies that they pursue the even tenor of their way, while other people take orders from the metal selling agencies and get entangled in market complexities.

BY THE COURTESY of Mr. E. Jacobs, the secretary of the Western Branch of the Canadian Mining Institute, we have received an account of the first meeting of that organization, as held at Nelson, British Columbia, on January 15 and 16. The attendance was good, it was representative, and keenly interested in the proceedings. Mr. Frederic Keffer, the president of the parent Institute, was in the chair. On the first day Mr. A. B. W. Hodges was elected president of the branch association. It was decided to hold three meetings each year. Many new members were elected and it is expected that the organization of the branch will result in a large addition to the membership of the Institute. Owing to the fact that the mining districts of British Columbia are distant from the central points at which the Institute usually meets, it was argued that a local auxiliary organization would be of great service both to the mining industry of British Columbia and to the Institute itself, stimulating both. A good start has been made. We shall watch the experiment with interest, for it may suggest a simi-

lar departure on this side of the boundary, with the formation of a Pacific branch of the American Institute of Mining Engineers.

The Goldfield Strike.

THE march of events in Nevada has been rapid. By request of the Governor of the State, the President ordered Federal troops to Goldfield on December 4; a week later three commissioners were sent from Washington to ascertain the facts; they arrived on December 16, and upon the presentation of their report the President telegraphed to the Governor that the troops would be withdrawn on December 30, unless he called the Legislature in special session to provide means for policing the disturbed district. Thereupon the Legislature was convened for January 14. On the opening of the session a resolution was passed asking the President to permit the troops to remain at Goldfield pending the organization of a State constabulary. The President acquiesced. On January 24 the Nevada Senate passed the bill creating a constabulary, to consist of a force of 250 men, and on the same day a majority in the Assembly voted to request the Mineowners Association of Goldfield to abolish the card system, by which the members of the Western Federation of Miners are proscribed. This demand being accepted, the Assembly passed the bill creating the State constabulary, and it became law by the signature of the Governor. It is recognized now that the operators at Goldfield made a mistake in lowering wages and issuing a ban against the Western Federation at the very moment when the troops arrived; it was this coincidence that led to the Federal investigation. By withdrawing the card system and requiring only a proof of competency and reliability on the part of those applying for work, the operators have recognized the force of public opinion. Black-listing is the complement of boycotting, both are tyrannical and unfair. An employer has the right to refuse to engage any workman he does not want, but he has no right to discriminate against a man on account of his membership in any club, church, or association until such organization has been declared illegal by proper process of law. The open shop is a snare and delusion unless it means the absence of discrimination as between union and non-union men. A man is as much entitled to be a member of a union as an employer has to be a stockholder in a corporation or a member of an operators association. If the mine-owners want to free themselves from the tyrannical interference of the rowdy element in the Western Federation they will do so best by giving fair treatment to those members of the Federation who themselves object to such of their leaders as are responsible for the brutalities and atrocities perpetrated in Colorado, Idaho, and Nevada during the last ten years. By trying to be just and fair, the mine-owners will get the support of public opinion and this in the end will give them more of protection than any constabulary such as is now to be organized. We have no great confidence in this volunteer police. The men are to receive $20 per *week*, a fact worthy of mention in contrast to the $13 per *month* paid to the enlisted men of the regular Army. The higher pay recognizes that the force is to be recruited from among a community accustomed to high wages, but the members of the constabulary will be, like the militia of neighboring States, efficient for defence against a foreign foe but incompetent as a protection against domestic turmoil. They have not the military instinct of the regulars and are half-hearted in their obedience to orders requiring them to proceed against their friends and acquaintances, whether mine operators or mine workers. So, after a brief and unsatisfactory experiment, we expect to see the Governor of Nevada and the Legislature appealing again to Washington for Federal troops and the eventual establishment of an Army post in Nevada.

In the meanwhile conditions at Goldfield are steadily improving. Many miners are returning to work and a few have come into the district from Utah and California. The new arrivals have not been intimidated by the pickets of the Western Federation, for local opinion is opposed to lengthened inactivity at the mines. It is the general belief that 75 per cent of the members of the Federation will be glad to return to work if they can be assured of protection, and the abrogation of the card system will encourage these more desirable men to break away from the extremists. We hope soon to be able to report that the strike at Goldfield is at an end.

Inventions and Patents.

HUMOR is the salt of literature and the savor of it makes digestible even technical contributions. A little of it is as welcome as sunshine after rain, for this is a dreary world and only the man of pleasant fancy and delicate wit can lighten the gloom of industrial depression. At least that is what Mr. Arthur DeW. Foote has done, for his letter on tube-mills and slime-filters is so seasoned with Attic salt that we find even the cyanide process deeply interesting and patents positively funny. All our cyanide experts will chuckle at the simple story he tells and some of them will even be generous enough to see that the joke is against them. The facts are clearly stated and in a courteous manner; no harm is done to anyone; some enlightenment is vouchsafed to those entangled in the battle of the processes; and, finally, a moral is pointed. With that moral we cordially agree. Patents are the outward and visible sign of inward and technical inventiveness, it is in the application of them that they are justified. To fight over priority of patents in a world running over with clever lawyers is to play into the hands of that one-eyed devil of litigation who too often usurps the place of blindfolded justice. If inventors will cease their bickering and set to work to show the managers of mines how to apply their new metallurgical and mechanical ideas, with the adoption of new devices and processes, we shall soon see a notable stimulus to industry. Moreover, the money that might otherwise be wasted in

litigation will become productive in the hands of our energetic engineers.

One paragraph in Mr. Foote's letter is particularly pleasing. Here is an engineer, in charge of one of the most notable mines in America, almost a veteran in years and more than a veteran in experience, who has hit upon a new idea and put it into mechanical shape. He is told—by our genial friend from Salt Lake—that his patent has been anticipated, but that the scheme will work. Is he chagrined? No. He says: "As we cared nothing about the patent, it was enough for us to have the assurance that the machine would work." That is it, let us have machines that will work and fuss less about the patents; let metallurgical specialists make money not by collecting—or threatening to collect—royalties on inventions, but by manufacturing special machinery and showing others how to use such machinery successfully. Not that we deny the right to a royalty on a basic patent. Once more we see demonstrated that in the evolution of scientific ideas and in the invention of the devices that embody them, there is a wireless telegraphy which conveys messages to those least intended to receive them and that one of the best tests of the value of a new idea is the fact that it occurs to the mind of more than one man at one time.

Two Copper Mines.

USUALLY we avoid discussing the market value of mining stocks, for accurate information is difficult to obtain and the subject is traversed by treacherous undercurrents. But on another page we give an analysis of the data obtainable concerning the production of the Anaconda and the Calumet & Hecla mines. The contributor to whom we owe this analysis is one well informed in such matters and without any financial interest in either of these two enterprises. As for ourselves, this is a fitting opportunity for stating that the editor of this journal has no dealings whatever in mining shares, directly or indirectly, believing that such aloofness from speculation is essential to unbiased judgment.

As to the Anaconda, the figures show that the mine has returned to the shareholders an annual dividend of $2.39 per share of $25 par value, that is, 9.52 per cent per annum. The average yearly profit per pound of fine copper has been 2.83 cents. There is some surplus of cash and supplies, the total liquid value of which is not known to the public. Each share is annually represented by an output of 84.4 pounds of copper. The value of the ore produced has fallen in ten years from $15.93 to $10.54 per ton, while costs have diminished much less, namely, from $9.30 to $8.01 per ton, the margin of profit being $6.63 in 1896 and $2.53 in 1906. It may be interesting to our readers to know that the cost of mining, transport of ore to smelter, and reduction there, with refining and marketing of bullion—that is, the total operating cost was in 1905, 12.4 cents, less 2.4 for precious metals, making 10 cents; while in 1906 it was 13.3 cents, less 2.2 for precious metals, making 11.1 cents per pound of fine copper. On 14-cent copper the profit is not quite 3 cents and of this over 2 cents is in precious metals, so that the profit on the copper itself is less than 1 cent per pound. As to ore reserves, the amount of them is not known; as to these and other matters the shareholders are not informed. If the reserves are such as to warrant the continuance of the past average production for a further 20 years, then the present value of the stock, giving an income of $2.39 per share, would, if capitalized at 5 per cent, be $29.30 as against the present quotation of $33. It is not likely that any investor would care to do business on such a basis, in a mine subject to the usual risks and in one that has already shown a diminishing ratio of profit. Of course, people that buy Anaconda shares are not investors, scarcely speculators, more properly gamblers, for the information given is too scant for guidance and like the Amalgamated, this stock is a blind pool of the kind dearly loved by manipulators. As a matter of fact, we believe that more money is made out of the ups and downs of Amalgamated and Anaconda stocks than in any exploitation of copper ore in the mines at Butte. The financial coterie controlling them can afford to keep these stocks far above their real value, even in times of panic, because of the use of the shares as counters in a game thoroughly under their control.

Turning to the Calumet & Hecla, the prospect is more pleasing. We note that the average annual dividend during the last ten years has been $52.50 per share, the average annual production per share has been 855 pounds of copper, and the average profit has been 6.1 cents per pound of fine copper. The present yield of $52.50 per annum, if capitalized at 5 per cent for 20 years, is $654. The market price of the stock just now is $665. Moreover, as the data quoted by our contributor show, the Calumet & Hecla company is building up a handsome reserve, both of money and of new mining property. The Calumet & Hecla mines are bottomed, that is, the conglomerate lode passes at the bottom into the Tamarack ground, so that further possibilities in depth are barred, but by exploratory work on the Osceola amygdaloid lode and by purchases of the control in the Allouez and Centennial mines, the future capacity for production is ensured. The affairs of the Calumet & Hecla are wanting in the publicity that is reasonably to be expected of all corporations that exist under the laws of the State and in virtue of the protection given by those laws; and this obligation exists despite the fact that speculation in Calumet & Hecla shares is confined mainly to the five or six hundred shares that are on the market, the large holdings being entirely non-speculative. While Messrs. Agassiz, Shaw, and Livermore have exhibited a secretiveness, as to technical matters, that bespeaks an unprogressive and rather selfish spirit, yet we are glad now, as in the past, to emphasize the honorable character of their business management and the fact that they do state the main facts to their shareholders, and we believe that the Calumet & Hecla is deservedly to be regarded as one of the best conducted mining enterprises in existence at this time.

Personal.

HENRY W. TURNER is here.

WALTER HOVEY HILL is at Seward, Alaska.

ARCHIBALD A. C. DICKSON is on his way from London to India.

GEORGE KISLINGBURY has returned to Los Angeles from Pioche, Nevada.

S. H. BRADY is superintendent of the Belmont mine at Tonopah, Nevada.

EDWIN H. DAVISON has left for Mexico in the interest of an Oakland syndicate.

GEORGE C. CARSON, of Vancouver, Wash., has gone to Shasta county, California.

F. M. KIRSCH, of the Pacific Tank Co., has returned to Los Angeles from Arizona.

W. T. HOLBERTON has been appointed manager of the Llallague tin mines in Bolivia.

W. A. CARLYLE has been appointed consulting engineer to the Le Roi Mining Company.

THOS. HUGHES, Jr., is superintendent of the Chesterfield mines, near Tucson, Arizona.

JOSEPH MCGILLIVRAY is preparing to operate a large hydraulic mine in Trinity county.

H. G. HEFFRON has been appointed manager of the Gold Road mine, at Gold Road, Arizona.

FRANK HOLMES is manager for the Palmarejo & Mexican Goldfields Co., at Chinipas, Mexico.

W. A. WILLIAMS is here, on his return from a two years engagement in Chihuahua, Mexico.

CHARLES BUTTERS sailed on the *City of Panama* on January 25, on his way to Copala, Mexico.

H. P. ROBERTSON is now manager for the Gwalia Consolidated Company, in Western Australia.

L. D. MILLS, of the Homestake Mining Co., is in San Francisco, on his way to Goldfield, Nevada.

ROBERT HAWXHURST Jr. is examining the Miño silver mines, in the province of Tarapaca, Chile.

W. W. ELMER, of Sumpter, Oregon, is manager for the Consolidated Mining Co., at Santa Barbara, Mexico.

S. SYKES, of Johannesburg, passed through San Francisco on his way from London to China and India.

EMILE R. ABADIE has moved his office from the Union Savings Bank Bdg., Oakland, to 422 Pacific Bdg., San Francisco.

EMILE R. ABADIE Jr. has returned to San Francisco from the mines of the United Mines Corporation in Tuolumne county, California.

F. M. LELAND resigned from the staff of the Risdon Iron Works recently to become manager of the Washington mine at French Gulch, California.

J. B. FLEMING has left the employment of the Joshua Hendy Iron Works to join the staff of the Goldfield Con. Mines Co. at Goldfield, Nevada, as mechanical engineer.

W. A. HEYWOOD has returned to London from Siberia. He goes shortly to South Africa to investigate the metallurgy of the Namaqua Copper ores.

GORDON F. JANNEY, who is operating a dredge on Clear Creek, in Shasta county, was here this week.

W. H. WEED is at Chilpancingo, Mexico.

GEORGE O. BRADLEY, chief engineer to the Utah Copper Co., has been tendered the position of general manager for the Pittsburg Silver Peak Mining Co., operating at Blair, Nevada.

ARTHUR L. WALKER has severed his connection as advisory metallurgist to the American Smelting & Refining Co.; he has opened an office as consulting engineer at 71 Broadway. On January 25 he left for Bermuda on a short holiday.

Nails, per keg	$3.20

General Mining News.

ALASKA.

(Special Correspondence).—Since the close of navigation several new and important placer discoveries have occurred on Seward Peninsula. Two of these are known as 'submarine beach pay-streaks,' (found in frozen ground below present sea-level) and have already developed into rich, paying properties. All are being tapped at about the same level by a continuous line of shafts on the divide between Penny and Snake rivers, west of Nome, and three-quarters of a mile south of the foothills. Kennedy, Brown & Bruner Bros. have located the pay-line at a depth of 112 ft. The submarine beach found by Seiffert, Gibson, Elliott and others, west of Nome is being followed in a continuous line to Penny river; heavy pay-dumps are manifest along the route. In places good pay-ore of great extent and value has been blocked out.——Halla & Webb are the fortunate discoverers of another rich beach-line that equals if not surpasses the famous 'third beach.' It was recently located about 360 ft. south of the former line, which ran through the Portland Beach, Bessie, and Cyrus Noble claims; it runs east and west, apparently paralleling its older rival.——A strange thing happened on Nov. 25. Volcanic ashes fell to such an extent over all parts of Seward Peninsula, from Kotsebue sound to Norton bay, that it covered the snow in many places like a great dark-brown blanket. The ashes were so gritty as to impede travel by sleigh and dog-teams everywhere. Natives from the Kobuk region arrived in Candle City yesterday and reported the disappearance of a prominent mountain near Cape Blossom, which sank amid "much noise, steam, and smoke" on Nov. 22. Thousands of tons of sandy ashes fell in Nome and vicinity, fully 250 miles south from the reported disturbance. A local chemist has promised an analysis of the strange substance, which, though very fine, greatly resembles the ruby sands found along the beaches of Bering sea.——The labor situation at Nome is growing acute and, although the Western Federation of Miners has practically won its closed shop regulation, a rigid adherence to this rule may prove very difficult. The latest move of this organization has been productive of great friction between the labor unions of this section. The cause of this difficulty is the persistent refusal of the Western Federation of Miners to recognize the cards of any of its local sister unions that are affiliated with the American Federation of Labor, except the Industrial Workers. An allied Trades Assembly has been formed in Nome to combat these conditions, and an attempt will be made to stop the Industrial Workers from 'scabbing' on members of the other unions. The latest addition of a number of Japanese, Russians, and Italians, into the ranks of the Industrial Workers has caused much comment and excitement among the laboring element, of which Nome has already an oversupply.——The Government has erected a Federal jail on the city square and a new edifice for the District Court, is in course of construction. Twelve acres of ground in the city of Nome have been requested from the trustees for the erection by the Government Telegraph Co. of a permanent wireless station, which will connect Nome direct with the States next summer.——The action of the Juneau Republican convention in repudiating Governor Hoggatt and Banker Whitehead, is generally acceptable to the people of Nome, who are nearly a unit for Cale and territorial government.

The pay-streak on the Lakeview claim, on the third beach-line, is without question the richest ever found in Alaska. Pans from $60 to $100 have been found and there is an extensive body of pay-gravel which readily yields $1 per pan without picking. The rich strike was made recently by Niebuhr & Bounds who are working the ground on a lease.

Nome, Dec. 7.

The indications are that 20,000 miners and prospectors will go to Alaskan camps during this year. The steamship *Saratoga* left Seattle, Wash., on Jan. 25 with 200 miners for Valdez and Cordova. The Tanana Mine Owners' Association is sending north 150 miners. Beginning in May, 8000 to 10,000 men, it is expected, will go to Nome and other Seward Peninsula camps. Prosperity and high wages obtain in every mining camp in Alaska.

ARIZONA.

COCHISE COUNTY.

The Supreme Court of Arizona has decided to compel J. N. Gaines, the tax collector of Cochise county, to collect in full the taxes assessed against the Copper Queen Co. for 1905; Gaines and the board of supervisors had compromised with the company for a considerably less sum than the amount due.——Rex McEwan has brought suit against the Denn-Arizona Mining Co. for $15,000 and costs of suit; he alleged that he has been crippled for life by injuries received from an accident in the shaft when the cage dropped onto the chairs at the 1100-ft. station with great velocity.—The Empire Copper & Gold Mining Co. has resumed sinking its two-compartment shaft at its mine near Johnson.

GILA COUNTY.

The Old Dominion company was forced recently to close one of its four furnaces on account of shortage in the supply of sulphide ore, but this will only be temporary, as sulphide ore from various outside camps has been contracted for and is now on the way to Globe. Work is being rapidly pushed on the 16th level of the Old Dominion mine; from this level the management hopes in time to extract sufficient sulphide ore to make shipment from the outside unnecessary.——Considerable excitement was caused in Globe by the reported gold strikes in Lost gulch and in the Pinal foothills 7 miles southwest of the city; rich samples were displayed in the city.——The National Mining & Exploration Co. has bought the Fumarole mine in the Gila mountains near Safford; a steam hoisting plant has been ordered for the property and a shaft will be sunk to a depth of 2000 ft.——The orebody exposed on the 450-ft. level of the Iron Cap mine is 30 in. wide; it carries 20% copper.——At the Gem shaft of the Globe Consolidated mine a crosscut is being driven on the 12th level.——At the Gibson mine 50 men are at work and shipments of ore are being made daily to the Old Dominion smelter.——T. E. Farish is developing the Independence mine; he is making shipments of high-grade sulphide ore.——It is said that a sample of the dump of a winze at the Black Hawk mine yielded at the rate of 10% copper, 4 oz. silver, and 0.02 oz. gold per ton.——It is reported that Charles E. Finney has secured $1,200,000 in Boston with which to build a 600-ton smelter on the property of the London-Arizona company near Winkelman on the Phoenix & Eastern railroad.

GRAHAM COUNTY.

It is announced that the directors of the Arizona Copper Co. have appropriated $100,000 for improvements in the smelter at Clifton; John W. Addies has been appointed consulting engineer and will have charge of the work on the improvements.

MARICOPA COUNTY.

It is reported that the Grand Traverse & Arizona Mining Co. has found a body of good ore at its mine in the Cave Creek district; C. F. Smurthwaite is general manager.——The Copper Top Co. has contractors at work on some of its claims.——Machinery is now enroute from Denver for the working of 2000 acres of placer ground near Wickenburg. The ground has been prospected by Barth & Holden, who claim that the gravel carries about $1 per ton.

PINAL COUNTY.

The new Imperial smelter, south of Red Rock, has been completed and blown in.——The Copper Butte Mining Co., it is expected, will resume work at once on its properties.——John McCabe is planning to build a 15-mile aerial tramway from the Silver King mine to Price station, where a 50-ton smelter is to be erected.

YAVAPAI COUNTY.

Th directors of the Jesse Mines Co. have decided to erect a 50-ton reduction plant; it will comprise stamps, concentrators, and a cyanide plant. The Jesse mine has a record in gold production of over $750,000; it is opened by a shaft 657 ft. deep, and it is said to have a large tonnage of ore ready to be stoped and treated as soon as the new mill is ready for operation.——Three tons of ore from the bottom of the 200-ft. shaft of the Square Deal mine in the Cherry Creek district were milled for a test; they yielded a bar weighing 5.34 oz. The shaft is on the hanging-wall of a large porphyry dike that contains several veins of gold ore.——The Majestic Mining Co. is unwatering the Lion shaft. It is also driving adits on other claims of the group; good ore is being mined from two of these adits.——The Climax Mining Co. recently made a test mill run of its ore; it is said the mine has a large tonnage of ore in reserve, and needs a larger milling plant.——Morgan Tillinghast of Philadelphia has made the final payment on the Monica group of mines; he has had this property under development for two years. The vein is cut at a depth of 1100 ft. by an adit 1300 ft. long. The vein is opened a distance of 1500 ft., the orebody being continuous the entire distance. The property also has a mill.——Ore averaging $100 gold per ton is being mined from an adit of the Wren mine in the Hassayampa district. High-grade ore has been found at a depth of 40 ft. in the Jayhawker mine, which is owned by the company that owns the Wren mine; R. A. Sweet is general manager.——It is reported a very promising gold strike has been made on an extension of the Rockefeller mine on the divide between Big Bug and Lynx creeks.—— At the United Verde smelter three furnaces are at work; the installation of new machinery with which to work the large new furnace is rapidly proceeding.

YUMA COUNTY.

A. W. Womble has been investigating the Amavista strike; he is reported to have said that it looks better with every additional foot of development.——E. Holden and T. J. Carrigan will put a force of men at work developing the Northern Light mine near Bill Williams Fork river.

CALIFORNIA.

AMADOR COUNTY.

Charles E. Hussner, who has been experimenting with the tailing from the Argonaut mill has arranged to install a plant and work this tailing; he hopes to catch the floating gold and amalgam that are now escaping from the mill.

CALAVERAS COUNTY.

The Melones mine was closed on Jan. 11 by a strike of the 175 employees, who demand a 9-hr. workday. The management is determined to make no concessions and it is generally expected that the struggle will be a bitter one. ——At the Boston mine an 1800-ft. three-quarter-inch steel cable has been put in; unwatering the mine is proceeding rapidly.——The work of repairing the Cross shaft of the Utica mine, which was damaged by a recent explosion, is advancing satisfactorily; the management expects to have the mine in operation in a few days.——Charles Hogan was assaulted and cruelly beaten by a gang of non-citizen miners at his home in Melones on the night of Jan. 19. His offense to them was that he would not unite with the strikers at the Melones mine. A citizens' protective association has been organized in Melones; this has let it be known that it has ropes and that trees are handy.

EL DORADO COUNTY.

Fred Schmeder has begun working his Barney mine.—— P. C. Drescher has purchased the Montauk Consolidated mine, in the northern part of the county; he intends to restore the mill and resume work in the mine.——Louis Koerber is working on his claim north of the Taylor mine. ——Preliminary work is to be begun at the Collins-Bacchi mine near Garden Valley for the sinking of a shaft 500-ft. deep; buildings will be erected and machinery hauled to the mine as soon as the roads are in good condition.

INYO COUNTY.

P. Calderwood and H. Scott have 12 men driving a 500-ft. adit at the Ubehebe mine; this adit will cut the vein 760 ft. below the outcrop.——At the Black Canyon mine an orebody has been cut by a drift 25 ft. long; it carries more gold than any other in the mine.——Al Stevens has a small force of men at work on his lease at the Brownie mine at Buena Vista.——Stocking & Denison are employing 15 men. ——The 3-stamp mill at the foot of Queen canyon is running on ore from a lease in the Buena Vista district; this ore carries $30 to $40 per ton.——The Bishop Creek Gold Co. spent in 1907, $91,107.33 in labor, machinery, and material.

KERN COUNTY.

B. Ostick and associates have secured $1200 in a three weeks' run of the Kinyon 2-stamp mill on ore from the G B mine.—Peter McMahon has taken a new lease on the Butte mine and has some men at work.

NEVADA COUNTY.

(Special Correspondence).—Good ore was recently struck in a winze in the Brunswick mine. Developments are going on at several points and a large force of men are employed; the mill is running on a fair grade of ore.——Sinking continues at the Central shaft; rapid work has been retarded by falling rock, but good progress is now being made and the shaft is considerably below the 5000-ft. point.——A full force of men is working at the Empire mine and a large tonnage of excellent quartz is being handled. Exploration and development work is going on in the lower levels. A large reserve of milling ore has been developed apart from the main lode.——Several men are working at the Conlan mine in accordance with a private agreement with the company. It is understood that they are working on a royalty basis. It is reported that good ore is being extracted.——The ore-shoot recently encountered at a depth of 800 ft. in the Idaho-Maryland is continuing to show well. Several men are employed and good ore has been extracted. The Sultana M. Co. is working a large force of men at its properties. Most of this work is being carried on through the Presscott Hill shaft. Good ore has been opened up at several points. C. K. Brockington is superintendent.—— The C. C. Mitchell ranch, lying near the Idaho-Maryland and Brunswick mines, has been acquired by the Lily G. M. Co., a Nevada City corporation, and will be extensively worked. There are three north and south lodes and an east and west vein. A shaft will be sunk and other work carried on. The ore assays from $1.60 to $20 per ton. The veins are from a few inches to 3 ft. wide.——About 40 men are working at the Pennsylvania mine; considerable exploration work is being carried on.——W. P. Martin and associates are developing a small body of good ore in the Golden Gate mine. The shaft is being sunk to enable the deposits to be worked at depth.——The Champion Mining Co. has a large force of men at work; a large tonnage of ore is being treated. Most of the high-grade ore is coming from the vicinity of the Home shaft, while a large quantity of lower grade has been developed in the old Champion workings.——The 10-stamp mill at the Ancho mine is running on good milling ore. The vein in the lower adit is showing improvement in size with depth. The working force has been increased.——Good results are being obtained from the working of several placers in the Washington district. Several men are employed and the season promises to be a very successful one.——The copper slump has forced the suspension of work on the copper prospects in the French Corral and Spenceville districts. It is reported that work will be resumed as soon as the market re-adjusts itself.——Robert Johnson reports that the antimony lode recently struck on his ranch, a few miles below Grass Valley, is showing up well with limited development. The lode is being prospected by Johnson and sons, who believe that they have the makings of a valuable property.——The present winter has been moderate and the mines have not been forced to use the large pumps which were installed last fall in anticipation of a

severe season. While the rain-fall is considerably less than that of last season, there has been heavy snow-falls in the adjacent mountains. This assures an adequate supply of water for the coming year.

Grass Valley, Jan. 27.

PLACER COUNTY.

R. L. Fletcher has four men at work at the Paragon mine; Tom Brown is in charge.——At the Three Star mine, stoping continues on the 1200-ft. level.——The adit at the Hidden Treasure mine is still being driven along the blue lead toward the old Mountain Gate mine.——The lessees of the Big Dipper mine are taking good gravel from new ground.——The Peckham Hill property has again been bonded.——The Bellevue company has decided to prosecute work on the 400-ft. level of its mine.——The Home Ticket mine at Last Chance is yielding good gravel; the manager is still following the Pennsylvania system of blocking out the gravel.

PLUMAS COUNTY.

A new company has recently overhauled the mill at the Plumas-Eureka mine and has built a tramway from the upper workings of the mine to the mill. The company has 25 or 30 men working, mostly stoping and driving.——The Little Jamison mill is temporarily closed down on account of shortage of water; 50 to 60 men are employed in the mine. S. W. Cheyney is superintendent.

SHASTA COUNTY.

The Summit group of 30 copper mining claims near the Mammoth mine has been sold by the Phoenix Securities Co. to the Stauffer Chemical Co. for cash.——Ore is now being taken from the Mammoth mine to a smelter over the new rail-track haulage system; the capacity of this system is much greater than that of the old aerial tram system.——The track of the Sacramento Valley & Eastern railway has reached Copper City. This will permit the shipment to Delamar of the great heaps of coke that lie at Pit station.——The oil storage tank for the Delamar smelter has been completed; the steel furnace stack is nearly finished.

SIERRA COUNTY.

While sinking a winze in the long adit of the Telegraph mine in search of a lost quartz vein, very rich gravel has been found. It is 3 ft. thick and is supposed to be a continuation of a gravel channel which was worked several years ago.——Piping has begun at the McNulty placer mine at Balsam flat; W. W. Tiner is superintendent.——A full force of men is at work again in the Young America gravel mine near Forest.——The Omega Gold Mining Co. has purchased a 3-stamp mill to treat the cemented gravel in its mine near Forest; Chas. H. Brown is superintendent.——It is reported that at the Ruby mine the vein has been cut in the adit and the company is now driving on it to get quartz for a mill-test.——At Sierra City a good deal of development work is being done in mines other than the Sierra Buttes; at the Cleveland mill eight stamps are dropping.——At Poker flat the Freeboroughs have finished a run of ore through their Huntington mill; the result is said to have been satisfactory.

SISKIYOU COUNTY.

Con Sullivan and William Ackers have found a gold-bearing porphyry dike in the Scott Mountain region, 9 miles south of Callahan; it is 20 ft. wide and ore taken from a 6-ft. shaft sunk in it carried $12 per ton.——Fifteen teams are hauling timber from the Manly saw-mill to the new dredge being built near Callahan by the Brownell & Mayhew Co.——S. R. Gardner and Abner Weed have merged their mining interests in the Quartz Valley district and they are expected to make a successful run this season.

TRINITY COUNTY.

Surveys for ditches and flumes have been commenced at the Quimby mine in the New River district. J. A. Brent is manager.——The Abram-Karsky Co. has won its suit against the Bullychoop Mining Co. to recover about $7000 claimed to be due the mercantile company for goods furnished to the Bullychoop company.

TUOLUMNE COUNTY.

It is reported that eastern parties have deposited a sufficient sum of money to practically assure that they will buy the Dutch Mining Co.'s property for a sum ample to pay every creditor 100 cents on the dollar.——The machinery for the United Mines mill is on the ground ready to be erected; the Lady Washington adit is being cleaned out.——Good ore from the New Albany mine is being crushed in the old Grizzly 20-stamp mill.

YUBA COUNTY.

Machines are to be installed at the Blue Point mine to work the dumps for the platinum that they contain. G. L. Holmes of San Francisco is selecting the site for the plant.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—A rich strike has just been made at the Columbia mine, situated on Silver mountain. The streak measures from 18 in. to 2 ft. wide, and carries $39 per ton in gold. Driving is in progress and as soon as the ground has been opened for 50 ft. stoping will be started. J. Graham, of Empire, is operating the property under lease.

Map of Northern California.

—Report is current that the Doric adit holdings will shortly be consolidated with those of the Capital M. & T. Co. The Doric adit is in Saxon mountain 3008 ft., and by running a lateral to the west the heading would cut the veins controlled by the Capital company at a depth of from 500 to 700 ft. under the present workings. The Capital company is being financed by four millionaires of Pittsburg, Pa., with Wm. M. Cooper of Georgetown serving as general manager.——The Hoery group of claims on Griffith mountain is being developed in an energetic manner. The adit is being driven steadily forward, and a cross vein will be reached within the next few feet. Considerable scattered mineral is showing in the heading, which carries much silver and lead.——Shipments have been inaugurated from the Gambetta vein, intersected through the Joplin adit. Stoping is in progress upon a streak of ore measuring from 12 to 15 in. wide; average returns of 70% lead and 48 oz. silver per ton are being realized. B. J. O'Connell of Georgetown is resident manager.——The adit being advanced to intersect the 700-ft. level of the shaft workings of the Shively mine is nearing the objective. There yet remains 75 ft. of ground to be broken, but headway is being made at the rate of from 3 to 4 ft. per day. With this work completed the old workings of the mine will be drained of their great bodies of water, while at the same time a good circulation of air will be obtained. B. J. Martelon of Silver Plume is superintendent.——The

Silver Leaf adit on Brown mountain is being advanced at the rate of 3 ft. per day, a Temple electric drill having been brought into use. Two veins have been passed, but no driving carried forward on them.——Work will be resumed in a few days upon the Charter-Raton group of claims, situated on Breckenridge mountain. The La Moe adit is to be continued on into the hill and according to surveys the Charter vein will be reached within 150 ft. A compressor plant was installed a few months since. J. J. Bonner of Georgetown is resident manager.——Chas. Carlson, leasing on the Lucky Hesperus mine, on Democrat mountain, has encountered a streak of 700 oz. silver ore and shipments will soon be started. The discovery was made in running a cross-cut to get under the old workings, whence some of the richest ore ever mined in the Georgetown district was taken a few years ago.——A carload shipment of smelting ore was made last week from the Sidney adit workings. The product was delivered at the Santiago sampler and settlement was made at the rate of 88 oz. silver per ton and 44% lead. Stoping is under way upon a streak of ore measuring from 4 in. to 2 ft. wide.——Chas. Jones, leasing on the Bellevue-Hudson mine, on Columbian mountain, has found a 14-in. vein of 147-oz. silver ore. The discovery was made in sinking a winze from the sixth or main level. Considerable water has been encountered and it will be necessary to install a pump at an early date. ——A night shift has been put on at the American Sisters 50-ton mill. The mill is to be fed upon the higher grade ore, as it has been decided to discontinue the treatment of the lead and zinc until the price of those two metals has advanced. The last shipment of concentrate after being run in two classes brought returns of 300 and 97 oz. silver per ton and 25% lead. Over 300 tons of smelting ore awaits shipment; it will mill better than 300 oz. silver per ton. J. J. White of Georgetown is general manager.

Georgetown, Jan. 27.

IDAHO.

BLAINE COUNTY.

Sinking has been suspended in the shaft of the Idaho Consolidated Mines Co. until the completion of the electric power plant. Work on the mill is being hurried, with the intention of completing the plant before the middle of April. Aldred & Smith, the contractors for the Idaho Consolidated dam, are importing teams and men from Utah.

IDAHO COUNTY.

A good body of free-milling gold ore has been found at the Star mine.——It is reported that the owners of the Butte-Orogrande mine intend to resume operations in the spring. The cyanide plant is to be replaced by a mill using a new process for reduction of ore.——A five-stamp mill will be erected at the South Fork mine as soon as the weather will permit.

LEMHI COUNTY.

(Special Correspondence).—The Lemhi Smelting Co. has been organized by D. E. Coughanour, H. L. Fisher, A. E. Carlson, H. E. Neal, and C. M. Stolle, of Boise, to erect a one-furnace lead smelter at a place between Spring mountain and the Gilmore mine, 70 miles west of Dubois station on the Oregon Short Line. It is stated that the ore supply will come from the Iron Mask, High Ore, Russell, Bruce, Forrester, Lemhi, Gilmore, and other mines. The ores of the locality comprise lead carbonate and galena, accompanied by silver and gold.

Salmon City, Jan. 25.

OWYHEE COUNTY.

Ore has been found in the upraise at the Village Blacksmith mine; several tons of it in a bin at the mouth of the adit contain $100 per ton.——At the Potosi mine a station is being cut preparatory to driving on the lowest level where the vein has recently been found in a cross-cut.——The Banner mill building has been completed and a transformer building is being erected. Two batteries, a 35-h.p. motor, pans and settlers have arrived at the property. A body of high-grade ore has been cut in the mine.

SHOSHONE COUNTY.

It is announced that the Panhandle smelter will resume operations about Feb. 1; it is to handle 6000 tons of ore per month. The Pennsylvania Smelting Co. will have a one-third interest, several of the producing mines in the Coeur d'Alene will have one-third and J. H. Anderson and associates the remaining interest in the ownership of the smelter.

NEVADA.

ELKO COUNTY.

Much development work is being done at Gold Circle.——W. D. McClelland and John Slaven have found at their Water Witch claim an orebody 18 in. wide; the ore is said to carry $75 per ton.——B. S. Tracey and associates are working the Elko Prince group of claims; they have found a lode 4 ft. wide containing ore carrying $5 to $114 per ton.——Some good gold ore has been found at Frazer creek and between Frazer creek and Scraper spring, five miles northeast of Summit townsite.——Two shafts on the property of Henderson & Pixley, 20 miles north of Carlin, develop an orebody 18 in. wide, that is said to carry 407 oz. silver and $2 gold per ton, besides a high percentage of lead.

ESMERALDA COUNTY.

The Nevada Legislature's police bill, which provides for a superintendent, inspector, sergeants, 25 subordinate officers, and 250 privates, was passed by the Senate on Jan. 24. It was then held up by a committee of the Assembly, pending a decision by the Goldfield Mine Operators' Association to abolish the card system, which required all employees to sign an agreement renouncing the Western Federation of Miners. On Jan. 27 the open-shop policy was adopted at the Goldfield mines; on the same date the Assembly passed the police bill. A bill was introduced in the Senate on Jan. 28 which will make it possible for the Attorney-General to remove the District Attorney at Goldfield, who, it is alleged, may have failed to perform the duties of his office.——The Combination mill is treating 90 tons of ore per day and there is a sufficient force of men at work in the Combination mine to keep the mill supplied with ore and further the development of the orebodies.——At the Mohawk mine men are opening up the orebodies on the lower levels and sinking the main shaft; no ore is being broken for the market.——Grading for the big new mill of the Goldfield Consolidated Mines Co. is progressing; 35 men are working at it.——The Gotwaldt lease on Combination No. 1 claim is expected to be the next shipper from Goldfield Consolidated ground; at a depth of 94 ft. the vertical working shaft has cut what is presumed to be the old Reilly lode. An electric hoisting plant is being added to the lease's equipment.——The Goldfield Mine Owners' Association announced on Jan. 24 that it could find places for 1000 miners at once. Local miners will be given the preference, but if the requisite number is not obtainable, men will be brought in from Utah.——More rich strikes are reported from the Rawhide district. On the Grutt lease there has been uncovered a body of ore that may be very large. One piece a foot long and 6 in. wide fairly bristled with gold.——Frank Boehme and others have bought the Murray lease and the Drew group of claims north of Grutt hill.——The Stinson lease on the Tiger group of claims has been sold to Colorado and New York capitalists.——On the Vickers property at Stimler, 28 leases are being worked; 18 of them are in ore. The shaft at the Irwin-Watson lease is 83 ft. deep; 40 to 50 sacks of ore carrying $150 per ton are being shipped daily. ——A hoisting plant is being taken from Goldfield to Rawhide to be installed on the Balloon lease.

HUMBOLDT COUNTY.

Copper stains are appearing in the ore of the Seven Troughs mine; this is considered a good indication; 35 men are employed.——The Glasgow & Western Exploration Co. is working a large force of men at its mine and mill near Golconda.——Active work has been resumed at the Signal Peak mine near Vernon.

LINCOLN COUNTY.

The Mizpah Mining Co. has installed a 6-h.p. hoist and will resume sinking its shaft to the 200-ft. level.——On Jan. 15 water was struck in the new vertical shaft of the Blossom mine at a depth of 280 ft.; good ore extends across the bottom of the shaft.——At the Chiquita mine, 20 miles south of Searchlight, the mill is crushing high-grade ore.——W. R. Groff and E. S. Beeson, it is reported, have made a strike of very rich gold ore on the Esther group of claims.——The Nevada-Utah Corporation has added 30 men to its force at the Day mine; J. P. Gaskill is general manager.

NYE COUNTY.

The ore shipments over the Tonopah & Goldfield railroad for the week ending Jan. 23, as reported by the Western Ore Purchasing Co., consisted of 80 tons from the Tonopah Extension mine. The Tonopah company sent 3130 tons, the Belmont company 880 tons and the Montana Tonopah 1100 tons to the mills, making the total shipments for the week 5190. The total output of the Tonopah mines was 5190 tons, of an estimated value (the shipping ore being valued at $50 per ton and the milling ore at $20 per ton), of $106,000.——At the Montana Tonopah mine a large body of ore has been uncovered at the 600-ft. level; it is 5 ft. wide and much of it carries $35 per ton. The 40-stamp mill is running steadily, with satisfactory results.——The West End Consolidated Co. is prosecuting systematic work on the apex of the big vein to enable it to prove its connection with the MacNamara vein in the suit which will come up for trial in the district court next April.——The North Star company is driving westerly on the fault-plane encountered at the 1250-ft. level; ore is being stoped at the 900-ft. level.——At the Midway mine the winze which is being sunk from the 800-ft. level on the big vein that was encountered about 800 ft. north of the shaft is now down 90 ft. Arrangements have been made for the erection of a mill at the Golden Sceptre mine at Rhyolite.——The cyanide plant at the Gardner mill at Goldfield is to be removed to the Bullfrog Pioneer mine.——The Gold Bullfrog mill is in full operation; H. W. Preston is manager.——Five carloads of machinery have arrived for the Homestake King 25-stamp mill.——Another carload of concentrate has been shipped from the Shoshone mill; the covering for the cyanide vats is nearly finished.——Excavation for the 50-ton Springdale mill has been commenced.——John Lindblom has men working on the claims of the Lulu Mae Mining Co. in the Funeral range.——At the Solid Gold lease at Round Mountain pockets of wire gold encountered every day are extracted by hand.——Placer ground has been found in the vicinity of Silver Point.——A rich strike at Baxter Springs consists of a stringer ½ in. to 14 in. wide probably carrying $150 to $200 gold per ton; it was made on the property of the Baxter Springs M. & M. Co.——The big mill at the Johnie Consolidated mine is finished; it has 16 Nisson batteries. The capacity is 150 tons per day.——R. W. Sparling has taken a contract to treat the dump of the National Bank mine at Rhyolite and has begun work on the plant he proposes to erect.——Ten men will be added to the working force at the Bullfrog West Extension mine.——At the Hayseed mine near Lee, the drift on the 100-ft. level is 380 ft. long; it exposes ore supposed to carry $60 to $100 gold per ton.

Montana-Tonopah Mill.

The Midway Mine.

near Northport is giving employment to two shifts of men, driving on the vein on the 200-ft. level for the pay-shoot which goes down from the 100-ft. level.——The North Star Mining Co. promises to start active work on its mine on First Thought hill near Orient as soon as snow disappears. J. E. Pierell and George Sisler of Spokane are directors of the company.——The Spokane Lead Mines Co. at Metaline has nearly completed the installation of machinery for the concentrator and expects to have the mill running in a week or two; the mill building is finished.

Republic, Jan. 22.

WASHINGTON.

STEVENS COUNTY.

(Special Correspondence).—In the United Copper mine, in Chewelah district, a streak of ore about 2 ft. wide has been developed on the footwall of the vein in a drift about 300 ft. from the end of the adit; it is highly impregnated with native silver, an unusual occurrence in the district. At the end of the south drift the vein is 6 to 8 ft. wide, the full width being copper-bearing ore of good payable quality.——It is reported that good ore has been found at the bottom of the shaft of the Kettle River mine, near Rockcut. Manager E. W. Scothorn is arranging with his company for more extensive operations.——A shoot of ore carrying gold, silver, and copper is under development in the Twilight mine, on Jumbo mountain. The vein is at a contact between granite and porphyry.——The Sunset mine

CANADA.

BRITISH COLUMBIA.

The ore shipments from the mines of the Rossland district for the week ending Jan. 18 were as follows: Centre Star, 3330 tons; Le Roi, 1588; Le Roi No. 2, 463; total, 5381 tons. The shipments from the Boundary district were 16,359 tons; from the Slocan-Kootenay district, 2911 tons. At the smelter at Trail there was received during the week 4867 tons of ore. Besides that sent from Rossland, shipments were received as follows: St. Eugene, 332 tons; Ruth, 113; North Star, 90; Vancouver, 81; La Plata, 69; Nugget, 64; Arlington of Erie, 52; Rambler-Cariboo, 44; Standard, 38; Ferguson, 30; Whitewater Deep, 23; Canadian Group, 22; Emerald, 21; Sunset, 21; Reco, 20; Keystone, 20; Sunshine, 20; Hewitt, 20 tons. The receipts of ore at the Le Roi smelter at Northport consisted of 1609 tons received from mines as follows: Le Roi, 1588 tons; First Thought, 21 tons.

Special Correspondence.

LONDON.

Gold Mining in Egypt.—Stratton's Independence.—Broken Hill Mines.—Record of Concentration.—Australian Smelting Corporation.

It is not altogether a surprise to hear that the recently created Department of Mines in Egypt is to be suppressed at an early date. The Egyptian Government and its English advisors have never been very friendly to the mining industry, and prospecting and development have never been free to any comer. Instead of letting the poor but practical prospector scratch the earth and roam about at will, they mapped out the country into sections and the right to prospect was sold to corporations or to individuals who could put up a good deal of money. Up to the present time most of the prospecting has been done by three influential groups, represented respectively by John Taylor & Sons, Lake & Currie, and C. J. Alford. Such gold mines as have been reopened, have proved lean and patchy, and have scarcely been successes. A few years ago a Department of Mines was established as a branch of the Ministry of Finance, and Mr. Wells and Mr. Greaves, who had previously been in the service of the Lake & Currie group, were appointed as chief and assistant. Money was liberally spent with the alleged object of popularizing Egypt as a country for mining operations. It was not a surprise, however, to hear that the Government, finding their schemes unsuccessful, had decided to drop the matter. At the present time the irrigation of the country absorbs the attention of the Government and its engineers, and great advances are being made in utilizing the waters of the Nile for the purpose of enriching the soil of the adjacent desert. With regard to the gold deposits, it seems to me probable that they were mined and exhausted thousands of years ago. History and tradition point to the riches of the country in by-gone ages, and the engineers who were capable of building the Pyramids may have known something of gold-milling and extraction.

The annual report of Stratton's Independence has been published this week. It gives the financial results of the operations during the year July 1, 1906, to June 30, 1907, and it contains a more recent report by Mr. Philip Argall relating to the prospects of the new plant for treating the low-grade and dump ores. During the twelve months, the operations were entirely done by lessees. They produced 38,880 tons of ore, of which 13,951 tons were shipped to the smelters and the remainder added to the dump. This ore realized £124,219, or, after deducting freight and treatment, £91,842. Of this sum £58,254 was paid to the lessees and £33,588 retained by the company. After paying £15,515 for mining and general expenses and paying other items, the net profit of the company for the year was £14,144, which, added to £25,090 balance brought in from the previous year, makes a total of £39,235 balance in hand. At about the time when the financial year closed the company took hold once more of the mine with the object of examining the bodies of low-grade ore still remaining in the stopes, so that at the present time there is little being done by the lessees. Owing to the methods of mining pursued by the lessees, involving the extraction of ore without doing any timbering, the mine is caved at many points, and it is probable that the caving system will have to be adopted in removing the remaining low-grade ore. The wet mill for treating the dump is in course of erection, and the first unit for handling 5000 tons per month should be in operation by the middle of February. When some of the dump is cleared away, there will be sufficient space available for erecting the second unit, say in six months time. The combination mill for treating the better-grade ore from the mine should be completed by the first of March. This mill has a capacity of 50 tons per day, but at small expense it can be doubled. The breaker for treating the low-grade ores from the mine is under construction. This breaker will reduce the rock to cubes of three or four inches. The friable ore occurring in very thin veins in this rock will be released as fine, which will be sent to the other mill, while the coarse rock will be thrown away. Mr. Argall estimates that on the dump and in the mine there is ore enough to last for eight or ten years at the rate of 10,000 tons per month, and that the profit should be $1 per ton.

A week or two ago I mentioned the case of the Sulphide Corporation, owning the Central Mine at Broken Hill. This week the reports of two other Broken Hill companies, namely Block 10 and Block 14, have been issued. Block 10 has been a regular dividend payer since 1890, and Block 14 has also paid good dividends, though not so uniformly successful. The two reports just issued cover the six months ended September 30 last. Block 10 company made a working profit of £57,790 and received £10,000 as an installment on the payment for its zinc tailing. Dividends amounting to £50,000 were distributed out of the profits. With regard to the concentration of the ore, it is noteworthy that more stuff now goes over tables than jigs, thus showing a change in the nature of the ore. The lead concentrate obtained showed a recovery of 67.66% of the lead contents of the crude ore, and 36.16% of the silver. The latter is allied chiefly with the zinc and will be recovered with it when the zinc tailing is treated by the zinc people. A very good idea of the nature and duty of the concentrating plant is given by the following statement.

CRUDE ORE TREATED, 73,816 TONS.

	Tons.	Silver, Oz.	Lead, %	Zinc, %
Lead Concentrate	11,596	31.59	60.02	9.86
Zinciferous Tailing.				
Jig Tailing	21,953	6.62	4.11	15.73
Vanner Tailing	6,167	10.39	6.19	22.24
Jig Middling	16,799	9.94	6.18	22.05
Wilfley Tailing	1,751	7.73	4.89	18.96
Wilfley Extension Tailing	1,360	9.15	5.92	19.0
Re-ground Tailing	2,183	8.39	3.6	22.82
Slime	12,043	14.78	10.79	22.8

Block 14 company treated 46,197 tons of sul-

phides and 10,622 tons of carbonate, and made a net profit of £72,490. The average assay value of the sulphides was 12% lead, 9 oz. silver, and 10% zinc. A recovery of 64.9% of lead and 41% of silver was obtained. The lead concentrate was 5924 tons, assaying 61% lead, 29 oz. silver, and 5½% zinc. The zinc tailing is being stored for future treatment or disposal. As I mentioned last week, the directors of the Australian Smelting Corporation have been forced to propose a reconstruction of the company to provide further working capital. The proposition came before a meeting of shareholders this week and an acrimonious discussion took place. Finally the proposition was carried against the dissentients.

Western Australia.

F. A. Govett, chairman of Broken Hill South Blocks Ltd. brought some comfort to the meeting by saying that his company was anxious to give the Corporation its smelting contracts, and he also hinted that there was some probability of the necessary money being found in Melbourne, thus rendering it unnecessary to proceed with the reconstruction after all. Let us hope that his surmise will come true, and that the English shareholders will not be called on to pay up this assessment.

One of the big West Australian companies, the Oroya-Brownhill, has had to announce that its main source of high-grade ore is rapidly dwindling and that for a time the output will have to be reduced. Two months ago, the news was published that an intrusion had been cut in the ore-pipe at the No. 5 level in the Oroya North Block. Since then, further developments have not improved the position, and the rich ore from this part of the mine, on which the maintenance of the present output depended, is becoming rapidly exhausted. There are, however, large bodies of low-grade ore and the company will still be able to pay some very fair dividends.

ROSSLAND, BRITISH COLUMBIA.

Shipments of Ore.—The Granby Co.—Annual Meetings.—Cost of Producing Copper.

Considering general conditions, mining affairs are quite active in this district, although several of the big mines have not resumed work yet. The Le Roi is working steadily and shipping about 1600 tons of gold-copper ore per week; the Centre Star is shipping approximately 3330 tons per week. The latter has a large quantity of good ore in reserve and in

Map of Part of British Columbia.

one of the lodes they have found free gold. Ore taken from this vein and shipped ran $40 per ton. This is encouraging when it is known that the general run of the mine only goes about $13.

The Granby is the only shipper in the Boundary district since the recent close-down. They are shipping about 16,500 tons per day and the smelter is putting through about 17,400 tons per day. It is expected that the seventh furnace at the smelter will be started within a day or two, which will give a total capacity of 3000 tons daily. It is hoped that the B. C. Copper Co. will make a move to resume operation shortly after the annual meeting, which will be held at Charleston, W. Va., on February 11. It is also expected that something will be done at the meeting of the Dominion Copper Co. to be held at Phoenix, B. C., on January 27. However, it is understood that perfect harmony is necessary for the profitable operation of these properties under present conditions. The mine operators, coke and coal producers, and the miners themselves must all pull together, as it costs the Granby about 10.13c. to

mine, smelt, refine, and sell its copper; it costs the B. C. Copper around 12½c., and for the fiscal year ended July 31 it cost the Dominion Copper Co. around 14c. to realize upon its copper. The Hewitt Mining Co., a New York enterprise in the Slocan, has made many improvements and great headway on the properties they have bonded. They have recently shipped five cars of silver-lead ore averaging 141 oz. silver and 5% lead.

The output of the Rossland Mines for the last 14 years has been 2,879,833 tons of gold-copper ore the estimated value of which is $40,279,421. Coal mining and coke-making is quiet in the Crows Nest Pass district. No doubt this is partly due to some of the Boundary mines being shut down, but one coal mine has closed down pending the renewal of a coal contract with the Canadian Pacific Railway Company.

DENVER, COLORADO.

Golden Cycle Mill in Full Operation.—Aid to Mining Schools.—Company Litigation.—Lawsuits Settled.—The Cripple Creek Adit.—Sunday Closing.

The Golden Cycle mill at Colorado City has fired up its eighth and last roaster and is now running at full capacity. The work on the new sampling building for the same plant is being pushed as rapidly as possible. The plant when complete will have cost $1,250,000.

Representative Haggott has introduced a bill at Washington that is calculated to benefit the mining industry. The bill is for the application of a portion of the proceeds from the sale of public lands to the endowment of schools of mining or departments of mining in State educational institutions. The bill provides for the payment to States maintaining such institutions of $15,000 the first year and an additional $1000 each succeeding year until annual payments of $25,000 are reached, which shall be continued thereafter.

The six directors of the El Paso Consolidated Gold Mining Co. have issued a circular answering the charges of A. L. Burris, who is making a fight for control of the company. The reason for giving up the contract on the Cripple Creek adit is stated as inability to make the required progress without a continued loss of money. Mr. Burris has replied to the circular of the directors by issuing his fifth circular to the stockholders. By the time of the annual meeting, on March 9, the El Paso stockholders should be well informed concerning their holdings as they are receiving the benefit of a lively publicity campaign. Several lawsuits have been settled by various mining companies within the last week. Three cases, aggregating $8,100,000, against the Stratton estate were settled by the payment of $4000. Comment upon the greed of claimants is unnecessary. The Portland Gold Mining Co. has been successful in the suit against it by Frederick Herman, a former employee. Herman claimed that the company was using methods patented by him without his consent. The District Court at Leadville has returned judgments aggregating $20,000 in favor of the Fanny Rawlins Mining Co. The suit was brought to recover the value of ore mined by the owners of the adjoining St. Louis claim.

The contract for the remainder of the deep drainage adit at Cripple Creek has been let to A. E. Carlton of Colorado Springs. Fourteen bids in all were received, and in awarding the contract the price, rate of progress, and reliability of the bidders were considered. As there remains more than 14,000 ft. of the original 15,500 ft. to be driven, it will require at least two years to complete the adit, and at $28 per linear foot the total cost will exceed $400,000. No contract has as yet been given for sinking the 600-ft. intermediate shaft.

The Sunday closing movement, started at Cripple Creek recently, has been partly successful. The Mine Owners Association has decided to close the mines on alternate Sundays. There has been a great deal of 'high-grading' in the camp, and after thoroughly discussing the matter, the association decided to leave the installation of the change-room system to the individual operators. While it is not expected that this practice will become general throughout the district, several of the mines will adopt the plan within a short time. The Mine Owners Association has issued 3750 of its new permit cards to miners since September, 1907. This indicates the largest number of men at work for several years.

Nearly all the available territory is now in demand by lessees. L. G. Carlton and associates have secured a two-year lease on the Pharmacist and a lease for a like length of time has been given to Gust Helien and associates on the Maggie claim. The large mines are being vigorously developed. The unwatering now in progress at the Vindicator mine on Bull hill and the Strong and Portland mines on Battle mountain has appreciably lowered the water in the other mines of the district and decreased the quantity flowing from the portal of the deep drainage adit.

BUTTE, MONTANA.

Great Falls Smelter.—Butte-Ballaklava Co.—The Reins Co.—Butte Coalition.—The Fire Underground.—Development of the Raven.

The Boston & Montana Co.'s smelter at Great Falls is now turning out about 5,000,000 lb. copper and 2,000,000 lb. matte monthly. This comprises the total production of the Amalgamated Copper Co. at present, and is equal to the combined output of the Great Falls and Washoe smelters prior to the shut-down of the Washoe. The electrolytic refinery at Great Falls has 376 electrolytic vats, 64 having been added during the past two years. Each vat is 9 ft. 9 in. long by 2 ft. 4 in. wide and 3 ft. 9 in. deep. The works at the Washoe smelter have 1400 vats in sets of 200 each, and the plant has a capacity for producing 9,000,000 lb. refined copper monthly. The Boston & Montana smelter has five blast-furnaces, three reverberatory furnaces, 22 McDougal roasters, 26 gas-producers, and 12 stalls of converters.

The Butte-Ballaklava Copper Co. has completed arrangements for installing a complete electrical plant to take the place of the temporary hoist, which has been in use since the company began shaft-sink-

ing. The equipment will include two compressors, a hoist of the latest design, and a pump for the 800 ft. station, all to be driven by electricity. A new head-frame is also to be erected.——J. M. Guffy, of Pittsburg, president of the Reins Copper Co., has filed for record an annual statement showing that the company has a capital stock of $3,000,000 and an indebtedness of $327,000. More than a hundred liens and attachments have been placed on the property of the company, consisting of the Combination, Ella, and Louise claims.——The Butte-Montana Mining Co., owner of the Alex Scott, reports an indebtedness of $39,190 and $791,507 in capital stock paid in. The company has not been doing any work on its property for some time, but the Boston & Montana Co. is sinking the Alex Scott shaft and driving levels for the purpose of getting a new inlet to the fire zone in the Leonard and Colusa mines.

During the general suspension of mining operations the Butte Coalition Co. is doing some good development work in the Rarus, Minnie Healey, and Tramway mines. On the 1600-ft. level of the Rarus the vein has been cross-cut and a drift is now being run in the ore, which is from 8 to 20 ft. wide, and assays up to 12% copper, the average, of course, being considerably lower than that. A cross-cut is also being driven from the 1700-ft. level, but the vein has not yet been reached. The shaft is down 1800 ft., and 75 ft. more will be added before another station is cut. Drifts are being advanced on the 1300, 1400, and 1500 ft. levels of the Rarus into the Minnie Healey ground and toward the new Tramway shaft, with which connection will be made. On the 1300 a fine body of ore has been opened in the Minnie Healey ground. The vein there is 100 ft. wide. The 1100-ft. level is the lowest working in the Minnie Healey itself, and there will be no connections made between the 1100 and the 1300 of the Rarus until it is certain that all the fire and gas are finally out of the upper workings. Sometime ago the Boston & Montana Co. tried to open the old Minnie Healey shaft for the purpose of using it in the fight against the fire in the old workings, but the shaft caved again and it has been abandoned. The fire is now under perfect control, but the fight to extinguish or confine it to a very limited area will be continued until the purpose is accomplished. In the course of this development work the Butte Coalition is taking out about 100 tons of ore daily, but none of it is being shipped to smelters. It is piled on the ground near the railroad track, where it will remain until there is a bigger demand for copper. The Tramway shaft has reached a depth of 1250 ft., and will be sunk at least 300 ft. more. All the mines of the Coalition Co. are in excellent condition, and when the metal situation becomes normal the company will be in shape for a big production. Most of the mining will be done through the new Tramway shaft.

The Raven Mining Co. has completed the Raven shaft to a depth of 1100 ft., at which point a station is being cut. The vein has not been seen below the 700, but on that level the main vein cut near the shaft on the north side, and a second vein was cut about 61 ft. farther north. The second vein is 26 ft. wide, and carries stringers of ore from one wall to the other, carrying some silver and copper and giving every indication of ore deeper down. The company is also driving a cross-cut on the 900 and expects to reach the same vein very soon. As soon as the station at the 1100 is completed a cross-cut will be driven from that point, and at the same time sinking will be resumed. It is the purpose of the company to take the shaft to a depth of 1500 ft. as rapidly as possible and open the veins at that depth. On the upper levels some lessees have been working and they have taken out some good ore, but the prohibitive rates charged by the smelters lately has interfered with shipments. The company has a large, 20 by 36 in. hoisting engine coming from Pittsburg, Ill., and it is expected to arrive in a few weeks. New skips are also coming. The new engine will be installed at the Raven shaft as soon as it arrives. It will be able to work to a depth of 2000 ft. The old dump near the mine has been hauled away and the ground cleaned up for new buildings. John Berkin, the general manager, is pushing the development work with all possible speed, and he is pleased with the appearance of the mine.

SALT LAKE, UTAH.

Utah Copper Co.—Boston Consolidated.—Honerine.—The Ontario Adit.—The Swansea Mine.—A Suit Compromised.—Yampa Smelter.

At a meeting of shareholders of the Utah Copper Co., at Jersey City, the capital stock was increased from $6,600,000 to $7,500,000; also the issue of $1,500,000 worth of bonds, bearing interest at the rate of 6% and convertible into stock at $20 per share. Following this action, D. C. Jackling, the manager, ordered the immediate completion of the four unfinished sections of the company's concentrating mill, with explicit instructions to have them all ready within 90 days. At the present time eight sections, capable of handling 500 tons of ore per day, are being operated. With the Copperton mill in Bingham canyon, the company will be in shape to handle an output of 7000 tons of ore per day. In a report submitted at the meeting, R. C. Gemmell, the superintendent, made the statement that since the company began production it had extracted from its Bingham mines a total of 1,300,000 tons of ore, and out of this amount, 400,000 had been taken out by means of steam-shovels. The mining costs this month will run about 30 cents per ton. The election of W. B. Thompson and Charles Hayden of Boston as directors is taken to indicate that in the future there will be a close alliance with the Guggenheim enterprises in Utah and Nevada.——The Boston Consolidated mill at Garfield is at work. Some delay was experienced in repairing the injury done to the pumping plant through the bursting of a large water-pipe recently; but the first section of the mill is now turning out concentrate.

Assurance has come from Park City that satisfactory headway is being made with the task of reclaiming the Ontario adit, which has been closed

by caves for nearly three years, greatly handicapping mining operations in the district, it having become impossible to operate the lower levels of the principal mines on account of the inflow of water. It is believed now that the last obstruction has been reached; this fact seems to have been demonstrated by the driving of several drill-holes from a parallel drift to the adit proper, a distance of about 27 ft. A vast volume of water backed by tremendous pressure is issuing from these holes. More holes are to be bored, and it is hoped in this manner to release the pent up waters.

A controlling interest in the Swansea mine at Tintic has passed to Jesse Knight and associates of Provo. Mr. Knight is also a controlling factor in the Tintic Smelting Co., which has under construction a smelter for the treatment of the ores of the Tintic district. The Swansea has been obtained principally for its usefulness as a source of water supply. The mine, however, has ore below the water-level, which is at 900 ft. This ore is particularly desirable for fluxing purposes. The smelter is about three-quarters of a mile from the Swansea mine.——The Colorado Mining Co. has succeeded in compromising the suit brought sometime ago against it by J. W. Wilson, one of the original incorporators. Wilson claimed that he had not received all the stock in the corporation which rightfully belonged to him and sued for $900,000 as the value of the stock and the dividends paid thereon. In compromising, Wilson agreed to accept $4500 in full settlement; the amount was paid him and the suit dismissed. The Yampa Smelting Co. has let a contract to the Allis-Chalmers Co. for two converter stands, blowing engine, steel building, etc., to be added to the equipment of its smelter near Bingham.

MEXICO.

Financial Conditions.—Reduction of Wages.

Many of the papers throughout the country have been trying to make themselves and the public believe that the banks and general business conditions were not affected by the financial troubles in the States, but the last few weeks have shown that at least one of the principal industries of the country has been very materially affected, and that is the cotton goods manufactures, so that it has necessitated a heavy curtailment in production and the laying off of much of the labor, especially in the great mills at Orizaba. And now another grave problem confronts the country in addition to that of the unemployed within its borders. The closing of the mines and various enterprises throughout the southwestern part of the United States has left without work many hundreds of Mexicans of those who migrated to the States, attracted there by the higher wages. Now, however, being without work, they are seeking their homes, but improvident as they always are, they have been able only to reach the border at El Paso, and there they lie stranded, and it is said that many are starving or suffering from sickness and disease brought on by exposure and lack of food. The care and disposition of these is a new problem which the Federal Government and the State of Chihuahua are endeavoring to meet.

Rather anticipating this general over-abundance of the unemployed, many districts have, as at Santa Barbara and Santa Eulalia, in Chihuahua, where wages have been cut from P1.50 to P1.25, taken advantage of the opportunity and reduced the wages to a scale more in conformity with the work done and services rendered. The boom times necessitated many raises to attract labor to remote localities or to induce the general run of Mexicans to work steadily at the most favorable prices. And an even further cut may be expected if conditions do not improve, as there are too many now seeking employment for the companies to continue paying the high wages which the Americans have brought into this country to their own undoing. And it is not only in the matter of wages that the American has thus hurt himself, but be it an apple or an orange, a suit of clothes, a piece of furniture, a horse, some land, or a mine, it matters not what, let the Mexican learn that the purchaser is an American, and up goes the price to double or more. Why is this? Partly because the American has had no better sense than to let the Mexican know that when given a price he always cut it in two as representing only half the price in American money; and also the American, being accustomed to good things in every line, when he sees a thing he likes, he will pay to get it. As a result he is held up, and the Mexican would rather not make the sale than let the American have it for less.

TORONTO, CANADA.

Branch Railroad.—A New Smelter.—News From Cobalt.—Prospects to the North.

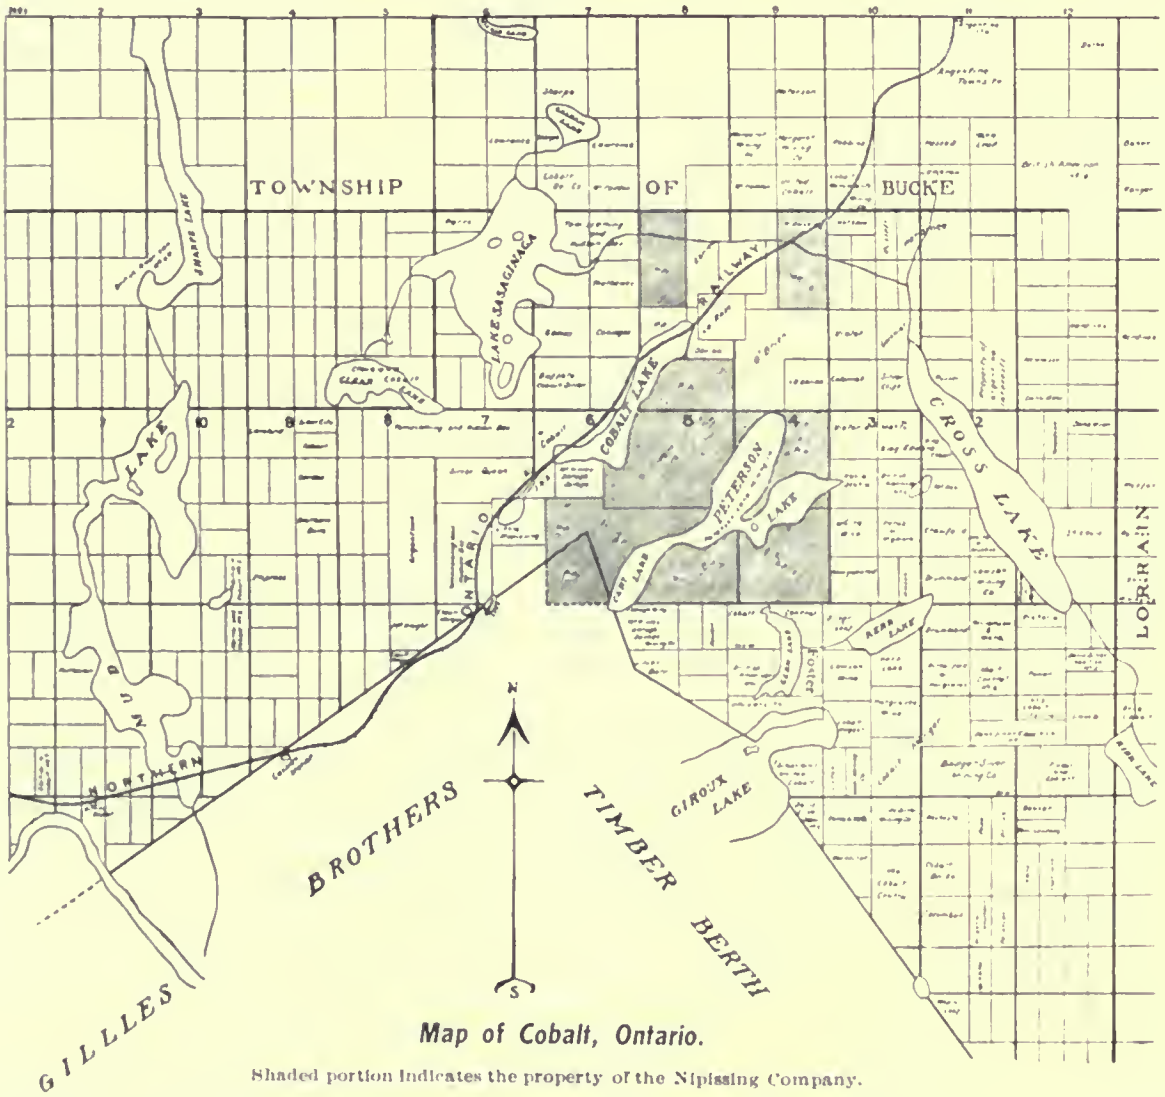
Construction work is being rapidly pushed on the Kerr Lake branch of the Temiskaming & Northern Ontario Railway, which is expected to be completed by the middle of February. It runs easterly from a point about a mile and a half south of Cobalt for a distance of 3½ miles, tapping a number of producing properties, including the Foster, Kerr Lake, Drummond, and University, and giving facilities to the Government mine on the Gillies Limit. Shipments will be made from the Gillies Limit as soon as the branch is completed, a quantity of ore being now in readiness.

The new smelter of the Montreal Smelting & Refining Co. near North Bay, Ontario, erected for the treatment of Cobalt ore, is now completed. The plant, on which about $750,000 was expended, was inspected recently by the Provincial Minister of Mines. The company has exhausted its resources and needs $50,000 to enable it to begin operations and has asked the Provincial Government to assist it in raising the money. Mr. Cochrane promised to lay the matter before his colleagues, but stated that he did not see his way clear to favor the proposal, as there were several smelters in the course of construction.——Shipments of ore from Cobalt for the year 1907 were 14,040 tons as compared with 5129 for 1906.——The Tretheway mine has realized $40,000 on a car of high-grade ore recently shipped. The ore stoped in the east drift of the old workings is valued at nearly $500,000. The vein in No. 2 shaft, which shows 8 in. of No. 1 ore at the 50-ft. level, has improved in value down to 90 ft.——At the O'Brien a vein of cobalt and native silver, varying in width from 3 to 5 in., has been struck at the 100 ft. level.——The Cobalt Contact is preparing to install a new plant, a portion of the machinery having arrived, preparatory to resuming mining operations

on an extensive scale. There are two cars of No. 1 ore awaiting shipment.——The main shaft of the Coniagas is down to the 150-ft. level and development work will be carried on extensively at this depth. Large additions will be made to the plant during the winter.——A good vein has been struck in driving at the Little Nipissing.——Extensive development work at the Red Rock has disclosed large quantities of low-grade ore. The management contemplates the installment of a plant to treat the low-grade ores on the spot, which seems to be the only plan by which the mine can be profitably run.

A prospecting party sent north from New Liskeard July 29 to examine the country up to James bay in the interests of the Trumpeter Syndicate, have reported results to T. H. Brooks, Toronto, representative of the syndicate. They found at Island Portage, on the Abitibi river, a formation similar in character to that of Larder lake. No placer deposits were encountered, but at Little Otter portage and on the boulders and gravel ridges below New Post, on Abitibi, numerous colors were found, but they were too pressed for time to make a close inspection. On the return by way of the Moose and Mattagami rivers they found copper indications between Grand Rapids and Little Long portage on the Mattagami. At Grand Rapids falls the bed of the river runs through extensive iron ore deposits about 100 miles north of the Grand Trunk Pacific route. They believe that close prospecting at several points on their route would reveal gold in paying quantities.

The official output of Cobalt has been announced as 14,813 tons, shipped by 29 mines during the year 1907. A few isolated shipments are made during the year from other shipping points than the town of Cobalt. The absence of these shipments from other tables accounts for the fact that the table now offered shows nearly 300 tons more than any other table published. The Cobalt Lake Co. has three carloads of ore ready for shipment and was entitled to rank among the shippers for 1907. Its managing director has however made no smelter contracts, and as the company has ample funds on hand for necessary development, it has been decided to store the ore in hopes of an increase in the price of silver.



Map of Cobalt, Ontario.

Shaded portion indicates the property of the Nipissing Company.

Total Shipments from Individual Mines in 1907.

	Tons.		Tons.
LaRose	2,851.02	Drummond	104.13
Nipissing	2,539.39	Green-Mehan	98.39
Coalagas	2,447.61	Cobalt-Central	77.33
O'Brien	1,436.76	Temiskaming-Cobalt	67.25
Buffalo	1,240.93	City of Cobalt	50.61
Tretheway	833.56	Silver Leaf	47.26
McKinley-Darragh	767.25	Colonial	40.38
Silver Queen	456.55	University	36.00
Foster	368.93	Watts Mine of King Edward group	31.17
Kerr Lake	323.19	Nancy-Helen	30.15
Nova Scotia	246.46	Red Rock	20.00
Temiscamingue	224.41	Imperial (Evans)	18.95
Cobalt Townsite	143.22	Princess	3.25
Tem. & Hud. Bay	180.41		
Right of Way	128.57		
Total tonnage for 1907			14,813.13

Year.	Tons.	Value.	Year.	Tons.	Value.
1904	158	$ 136,217	1906	5,129	$3,900,000
1905	2,141	1,473,196	1907	14,813.13	5,650,000

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

NO DUTY is collected on graphite imports.

THE study of the origin of ore deposits has a practical bearing on prospecting and on the valuation of mining properties; hence, theoretical studies should be welcomed by practical men.

THE deepest diamond-drill hole on record was put down in Upper Silesia in 1900 and reached a depth of 6700 ft. On the Rand, in South Africa, a Sullivan class P drill bored to 6340 ft. in 1905.

A DEPOSIT OF BISMUTH ORE of sufficient size to make its mining on a large scale worth while, would yield sufficient of the metal to reduce the market price to much less than it has been in recent years; but it is possible that if the market were not artificially contracted, and the metal were mined and smelted without restriction, new uses would be found for it, and manufacturing on a large scale might become a commercial success.

IN MEXICO ore is generally sacked so that the packages may weigh from 140 to 155 lb. each. Two of these make a load for a burro. When the ore is very heavy the two sacks that are packed on one burro may weigh nearly 200 lb. each. The trails are mostly down grade or level, with occasional short and steep or longer and more gradual ascents. The animals work under these loads for months without any apparent ill effect.

UNSLAKED OR FREE LIME is the greatest enemy of good portland cement, as its presence will cause the mortar to disintegrate gradually. To determine the presence or absence of harmful constituents a very simple test may be applied. Two pats of cement (without sand) should be mixed to the consistence of putty and placed on glass. Make them about three inches across and half an inch thick at the centre and tapering to a thin edge. Cover with a damp cloth for one day, then put one pat in water and let the other stay in air, preferably moist air. If the pat in air shows large yellow blotches after a time, or if the pat in water begins to show cracks, starting at the edge and running toward the centre (showing disintegration), the cement is not up to the standard.

COPPER ORES often contain deleterious minerals which cause trouble in their reduction. Bismuth is quite troublesome in some Australian ores, although since the general introduction of electrolytic refining it has ceased to be as objectionable as formerly. Arsenopyrite is a very common and obnoxious associate of copper ores; the same is true of antimony minerals. They are partly eliminated in modern smelting methods but only by the electrolytic refining process can the copper be made pure enough for electrical uses. Zinc, usually present in sphalerite, is the most obnoxious associate of copper. It is so troublesome in ordinary copper smelting that usually each percentage in excess of 10% is charged for at the rate of 25c. per unit; this is known as the 'zinc penalty.'

ELECTRIC HAULAGE is used underground at the Wesselton mine of the De Beers Consolidated Mines, Ltd. company, in South Africa. Electric trains, composed of 6 to 8 mine cars, each of 1 ton capacity, run at a speed of 15 miles per hour even around curves of 55 ft. radius; this is possible because the track is laid with 45-lb. steel rails with manganese steel fittings, points, and crossings. The motors have broad, flat, beak-shaped ends and resemble some types of racing motor-cars. The loaded cars are automatically tipped into capacious ore-chutes by running them over a curved rail placed at the exact angle necessary to tip over the loaded car and then let it fall back into its place again after emptying. The cost of electric transportation over a system having one-half mile run amounts to 1½d. per ton.

SOME idea of the cost of operating a mine in the outlying districts of Nevada may be had from the following list of prices of labor and material now in force at Manhattan, Nye county: Miners, driving, and trenching, $4.50; sinking or raising, $5; work in wet places, 50c. extra per shift; tool-sharpeners and blacksmiths, $5.50; timber-men, $5; hoist-engineers, $5.50; stoping, $5; machine-work, 50c. extra; all contract work, $1 more than company work. All prices for eight-hour shifts. Overtime is allowed only in cases of extreme necessity. Board costs $45 per month, rooms $10. Candles cost $7.50 per box; powder, No. 2 Hercules, 16½c. per lb.; No. 2 extra, 17c. per lb.; 3x caps, 90c. per 100; 5x caps, $1.25 per 100; fuse, (Bear), $33 per case of 6000 ft.; gasoline, Red Cross or Motor, $5.65 per case of 10 gallons; kerosene, $5.75 per case; drill-steel, 14c. per lb.; steel rails, 7c. per lb.; blacksmith coal, 5c. per lb.; wire nails, 9c. per lb.; rough lumber, $75 per 1000. These are net prices charged by local merchants, when goods are purchased in quantity.

A CONVENIENT METHOD for thawing powder at a small property where a gasoline hoist is used, is the following: Have a tank made large enough to hold a small water-tight powder-box, with plenty of room for water around the sides, top, and bottom. Tap a hole and put a turn-cock just above the engine-cylinder, in the vertical pipe that conveys the cooling-water from the cylinder to the cold-well. A small funnel and pipe will then convey this hot water from the engine-room to the thawer outside. If water is scarce, it may be drawn from a cock in the bottom of the larger tank, and returned to the cold-well after it has lost its heat. If the engine is not running enough to heat all the circulating water, turn off one of the valves in the circulation pipes, and boiling water will soon be had. If one charge of hot water does not soften the powder, two charges will probably do the work. In this way the powder is never near a fire, does not come in contact with any water, and no danger is incurred in the process.

THE rapid rise in the price of antimony in 1906 was not due to the exhaustion of mines as some supposed, but to the fact that the ore treated at important metallurgical works in France and Italy was largely converted into oxides and other salts, instead of into regulus as formerly. Both the Italian and French governments encouraged the use of antimony pigments, which have the advantage over white lead of being innocuous, and over zinc paint of being permanent and sun proof. The protection of these governments and a growing demand in England for antimony pigments caused the Société Anonyme Franco-Italienne to increase its paint production at the expense of the regulus output; other companies probably followed its example. At the same time there was an increased demand for the metal in the machine and industrial world, where antimony is obtaining a wide application in the manufacture of bearing-metal and other alloys, and is replacing soft lead for acid-proof linings, and for other purposes.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Mechanics of Ore-Crushing.

The Editor:

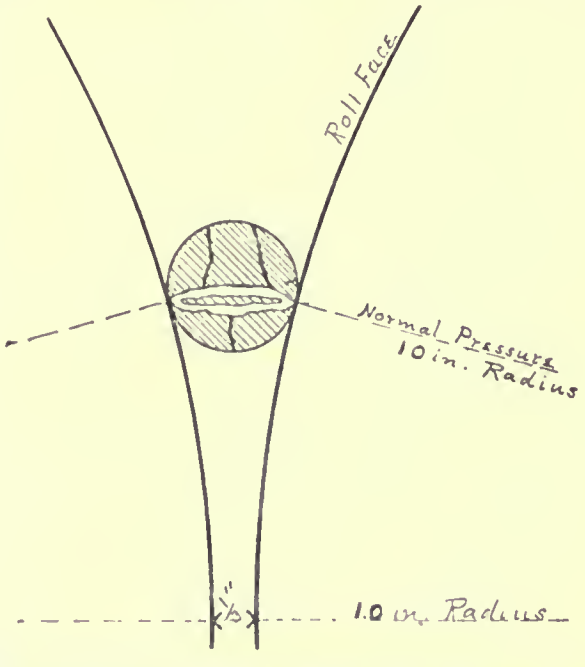
Sir—Mr. Ernest A. Hersam, in his paper on 'Economy of Power in Crushing Ore,' in your issue of November 16, has passed in review a large number of the conditions present in ore-breaking and comminution, and his paper in consequence is full of valuable suggestions. It may be taken as a starting point for a more exhaustive examination of the subject. This, however, necessitates the accumulation of experimental data, and only by such investigation can true and useful conclusions be drawn, capable of convenient expression in the form of working formulae. In the absence of such data the mathematical deductions presented in the paper can only be considered as applying to a very special set of conditions, and it is to be hoped that Prof. Hersam, with the laboratory facilities at his command, will extend his researches, and lead the way to a clearer comprehension of the phenomena of crushing, and of the economical application of power to produce desired results.

Although we have to deal with mixtures of irregular masses of many sizes in the practical crushing of rocks and ores, it is obvious that the initial step toward an understanding of the mathematical effects produced under complicated conditions can best be reached by an examination of the phenomena of crushing single masses of symmetrical shape. The average shapes of rock-fragments are approximately either spheroids or ellipsoids. The behavior of ore particles settling in water confirms this. Such being the case, we may properly begin our study by subjecting spheres to strains similar to those induced in ore-particles in practical crushing.

It has been my privilege to conduct a few experiments of this character, which were unfortunately interrupted before sufficient data for safe generalizations had been obtained. The results, however, were so uniform under similar conditions, and so different from those anticipated from theoretical considerations, as to emphasize the need of a thorough experimental investigation of the subject. As an example, it was found in the crushing of glass spheres 1 in. diam. in rolls set ½ in. apart, that with only a few exceptions in several hundred experiments the sphere ruptured into six principal pieces, five being relatively large fragments with irregular fracture-planes or surfaces, and one being an elongated fragment the length of which almost equaled the entire distance between the points of contact of the opposing roll-faces with the original sphere. The large fragments could be refitted in the great majority of cases so as to re-establish the sphere, which was then found to contain a hollow space having the form of an elongated ellipsoid terminating in small round openings at the points of contact with the roll-faces. The elongated fragment had come from this hollow space, which, however, it did not completely re-fill. A considerable quantity of small fragments and finely pulverized material had been produced in the interior of the sphere between the elongated fragment and the larger pieces. The volume of this interior ellipsoidal cavity, as determined by displacement of water, averaged about 10% of the whole, and the volume of the elongated fragment was about 4.5% of the entire sphere, leaving about 5.5% of relatively fine comminution as the result of a single passage of the sphere through the rolls.

In effect the tendency of the sphere under compression had been to behave as a beam between the points of application of the force, and to shear off all that portion not acting as such beam. Moreover the shape of the elongated fragment was approximately that of the figure produced by the lines of distribution of strain within a beam, as experimentally determined when compression is applied to the two ends thereof through simple points of contact.

It was also noted that the larger fragments commonly showed incipient concentric fracture-surfaces indicating the transmission of spherical waves of compression, starting from the points of contact with the rolls, and widening out therefrom. Exactly similar results in all details were obtained by crushing such spheres in rolls and in jaw-crushers. Subsequently, selected Baltic pebbles were crushed under like conditions, yielding similar results, sometimes as perfect as in the case of the glass spheres, but original planes of weakness in the pebbles usually modified the forms of the fragments materially. Selected pebbles of granitoid rocks from glacial moraines gave results more nearly approximating those with the glass



balls, except that the elongated fragment was more irregular in outline.

Very different results were obtained in crushing by stamps. In these experiments steel bars ¾ in. high, were placed in the die upon either side of the spheres, which were 1 in. diam. The stamp accordingly came to rest upon the steel bars; the crushing effect thus being due solely to impact of the falling stamp upon the sphere. The weight of the stamp was 850 lb., and height of drop to the steel bars 7½ in. In all cases the upper portion of the sphere was irregularly fractured, the lower portion was reduced to small particles and in the centre, in contact with the die, was found a quantity of finely comminuted material. Manifestly the comminution had been due to rupture produced by strains set up by reflected waves of compression meeting oncoming compressive waves.

Further experiments on the crushing of granite, syenite, and many varieties of ores, with and without disseminated sulphides of iron, copper, and lead, brought out a few surprising facts. It was found that materials that had been kiln-dried until they contained less than 2% moisture, yielded sizing-curves which were practically coincident when similar crushing conditions had been maintained, irrespective of the mineral composition of the material. It was also found that, when reducing ores in the normal way in rolls, intermediate screening out of

material finer than No. 28 mesh (0.6096 mm.) between successive crushings did not affect the sizing-curves of the total resultant product. It was further observed that the quantity of fine product rapidly increased with the quantity of water of imbibition in the ore up to about 7%. No measurement of power consumed was attempted, but sufficient has been stated to indicate how far we probably are from accurate knowledge of how mineral aggregates behave under the conditions of crushing, adequate for generalization and reduction to mathematical expressions. Systematic experimental investigation of these phenomena would undoubtedly lead to results of immense practical value.

Los Angeles, December 21.

Variations in Mining Costs.

The Editor:

Sir—Referring to Mr. J. R. Finlay's article in your issue of January 4, there is no doubt that the cost of treating ore should include all the items of expense entailed in the production, for after all the question is simply a matter of a return for money invested. No one goes into mining for the mere scientific knowledge that can be gained from operating, but entirely as a productive enterprise. Some expect quick returns, while others are satisfied with a fair interest. Mining for the precious metals has always had an element of uncertainty. We can estimate with fair accuracy the amount and value of ore already blocked out, but it is different to estimate the cost of finding other ore of equal value and the cost of its reduction, for conditions are changing. While the cost of exploiting and extracting the precious contents may be lessening by improved machinery, the difficulty due to increased depth and impoverished ore at greater depth may more than offset this decrease.

Work already done need not necessarily enter into the calculation of future exploitation at so much per ton, unless an equal amount of work is necessary to block out an equal amount of ore; in other words, the cost of development work should be that necessary to supply for every ton worked out another ton in its place. No two men look at a mine in the same light as to the method of future development, and consequently they will not necessarily agree as to the cost per ton of such development. The fact that a certain number of feet of opening was necessary to develop a certain amount of ore is not an argument for the same quantity of ore requiring the same amount of work.

Looking at it from the standpoint of the mine managers, I desire to point out to consulting engineers particularly that we are the meaus through which their estimates are put to the test, and that in all fairness we should be provided with the figures and means by which the anticipated results are to be obtained. An engineer figures out costs at so much per ton, having in mind the use of certain appliances and processes, but the superintendent may not have the good fortune to be provided with the means of applying these up-to-date methods. He may be compelled to use hand-labor where machine-drills were figured on, and so forth.

The variation in cost is so wide that the personal equation is the important factor in the estimate. Within the last two years I have known mines where the cost of mining and marketing ore varied from about $100 per ton at Cobalt, $14 per ton in Colorado, to $3 per ton in California. These costs varied with the size of vein, hardness of rock, amount of picking, efficiency of labor, and many other factors, the most difficult to estimate in advance being the cost of developing another ton of ore. This can only be gained from experience in many localities by the character of the deposit, and at best such a calculation is only a rough estimate, for nature has not provided a glass case by means of which the hidden recesses of the earth can be viewed, so I say: Gentlemen of the profession, kindly let this estimate include all possible contingencies so that the superintendent may be able to come up to your expectations, or it may happen that you will be the one to prove or disprove your own figures.

Generalizations are often misleading and may be derived from experience in a particular line, and while Mr. Finlay's observations may have led him to believe that high development costs are particularly characteristic of non-concentrating mines, it would be unwise to let this generalization influence an estimate unduly; rather, let us look the problem squarely in the face, tabulate facts, and make our figures accordingly.

ALGERNON DEL MAR.

San Francisco, January 16.

Psychology of Mining Booms.

The Editor:

Sir.—I have read with great interest the article by Mr. J. H. Curle entitled 'Psychology of Mining Booms,' which appeared in your issue of January 4. The interest aroused decided opposition to the views expressed and leaves a desire for contradiction.

You, as editor, in saying that you are "in accord with the tenor of his preachment," properly reflect, I judge, the opinion of a majority of the readers of the Mining and Scientific Press. It is this opinion, which I feel is pretty generally held by technical mining men, rather than the individual expressions of Mr. Curle, that I am anxious to combat. But 'Psychology of Mining Booms,' with its blunt effective statements, will serve as the convenient skeleton for me to clothe with the garment of objection.

I utterly oppose the general tenor of Mr. Curle's expressed views because, while one cannot misjudge their good intent, they are dangerously misleading and if accepted would impair many splendid and reasonable opportunities for profit and largely hinder the progress of metalliferous mining. I might also object because these expressions of technical mining men would seem to class the average investor, in their minds, as a brainless idiot. But this may not be intended although if one reasons it out from the Curle type of argument one must arrive at the conclusion that technical mining men consider the public fools and themselves the only ones to whom the Eastern star is visible.

Mr. Curle enumerates the mining booms with which he has become familiar and then says:

"These thirteen mining booms, following upon discoveries of more or less value, took without exception one definite course. After an initial period of scepticism results from one or two mines in the new district led to great financial excitement, and to wide advertisement. Outside promoters entered the field, and capital poured in; for one good mine twenty worthless ventures were floated; the shares, good and bad, rose to absurd prices; and the facts became obscured in an atmosphere of lying and brainless optimism. Then, sooner or later, came the crash. This was always thorough, and in

each case dragged down thousands of more or less foolish and deluded people."

Much more is said, but the pith of the article is contained in the above. It is evident that Mr. Curle does not believe that the discovery of one or two rich mines in a new district warrants financial excitement, wide advertisement, the investment of capital, speculation or optimism. It is with this view that I beg to differ. I submit that when results (proof of richness) from one or two mines in a new district are obtained, those to whom the opportunity is given would be perfect ninnies were they to fail to grasp the chance to acquire ownership in as much of the territory in the district as possible even though the cost might be out of all proportion to visible values. It is a speculation, of course, but one reasonable enough when one remembers that in all the boom camps of recent years the obtaining of results from one new mine has led to the discovery of many others.

In Cripple Creek the original discovery was made by Bob Womack. He staked the Gold King claim on Tenderfoot hill and subsequently a score of other properties, scattered over an area of several square miles, were opened up. They have yielded a hundred millions odd, to which the Gold King itself has contributed a comparatively small fraction.

In Tonopah the original discovery was made by Jim Butler when he staked the only visible mineral-bearing outcrop on Mt. Oddie and called it the Mizpah. Although other operators in this field had no veins to follow, their extensive development work has resulted in the opening up of a number of rich mines.

In Goldfield the original discovery was the Combination, staked by Myers and Murphy. The Mohawk, Jumbo, Florence, Sandstorm, Daisy, Red Top and several others were all subsequent discoveries.

In Bullfrog the original discovery made by 'Shorty' Harris was far distant from such properties as the Mayflower, Shoshone, Tramps, Homestake, Victor, Gold Bar and others. It is these latter properties which have made the district more permanently famous but they were discovered as a result of the location of the Original Bullfrog.

In Fairview the original discovery was rich float because of which many locations were made. The first location has not yet proved to be a mine but later prospectors opened up the Nevada Hills, Fairview Eagle, Eagles' Nest, Mizpah, and others.

In Manhattan the finding of rich ore on the Stray Dog, located by Seyler and Humphrey, has been followed by the development of other and more productive properties.

At various times the discoveries made in the Nevada camps enumerated have resulted in the finding of ore at many other points in the State, such as Round Mountain, Wonder, Gold Mountain, Rose Bud, Lee, Ely, Seven Troughs, et cetera.

In Cobalt the original find was made by McKinley and Darragh, who staked the rich mine of that name. Since then a number of other mines, including the famous Nipissing, carrying extraordinarily rich silver ores, have been opened up.

To summarize, we find that in six out of seven of the most recent boom camps—Cripple Creek, Goldfield, Bullfrog, Fairview, Manhattan, and Cobalt, more productive and more profitable mines were discovered after the original discovery was made, while in Tonopah alone the richest was discovered first and even here subsequent developments have opened up other rich dividend-paying mines.

Therefore I argue, aye insist, that after results have been proved in one property in a new district, optimism, advertising (dissemination of news), excitement, speculation, and advances in prices far beyond visible or proveable values is warranted. The district where one good mine is proved is the best place to try to find another. History perpetually repeats itself in giving proof of the fact that where one rich property is located others exist. So when one rich mine is found, the speculative value of the surrounding prospective territory becomes immediately and enormously enhanced. That an increase in these speculative values may be reasonably extended over territory for several miles from the original discovery is amply illustrated in the case of Cripple Creek, Bullfrog, and other camps. Stratton's Independence is three miles from the Gold King; the Montgomery Shoshone is four miles from the Original Bullfrog—and in other instances the distances between proved mines can be measured by miles. In all cases what may have been barren and worthless mountains or desert space assumes a considerable monetary value which in many instances it is, on a speculative basis, reasonable to pay.

Consequently when I see miners turning their capital and effort toward the development of prospective territory in a new camp; when the investor puts his money into the purchase of a property or acquires an interest in the same through stock purchases, I cannot class them as operating "in an atmosphere of lying and brainless optimism." Will Mr. Curle and the supporters of his argument say that the scores of operators in the camps I have named won success because "lies and foolish imaginings flourish." This certainly is the tenor of thought in 'Psychology of Mining Booms,' as it is made to apply to 90% of those who win fortune, for it is obvious that fully nine-tenths of all the big finds are made subsequent to the original discovery. According to the Curle theory, Stratton, because he chose to delve and prospect in Cripple Creek after the Gold King had been located, or the syndicate of Salt Lake capitalists who bought the Boulder claims (Nevada Hills Co.) for $5000 after Norton had discovered rich float two miles from the property, were "obscured in an atmosphere of lying and brainless optimism." I submit that one cannot argue that only those who were successful were wise while all others were possessed of "foolish imaginings." In my opinion Hayes and Monnette, who made millions out of the Mohawk, were no wiser speculators than the operators upon adjoining ground who may not have earned a penny of profit. Both undertook a reasonable speculation because each was operating in a camp where a rich mine had been proved.

Furthermore, I ask, are we to stop when results from one or two mines in a new camp have been obtained? Is it not reasonable to suppose that where one rich mine has been discovered another may be found? And if we have an ounce of business venture, of speculative instinct within us, would we not be like the much compared bumps on a log were we to fail to grasp such reasonable opportunities did they but come to us? How quickly the discovery and development of new mining camps would dwindle and how few would make profits from mining were investment to keep pace only with the theories of the technical!

And one of the theories of the technical mining man, who is so vastly useful in his own sphere, is expressed by Mr. Curle when he says that thousands of more or less foolish and deluded people are dragged down by investment in mining. The professional mining man seems to believe that spread over this fair land of ours there are thousands of people who have been financially ruined through investment in mining. He also delights to imagine that they are of the brainless optimist and foolish imagining type fit for little else than the insane asylum. As a matter of fact, your average investor in mines or mining stock is an average business man of average sense—neither better nor worse than the average professional mining man. Furthermore, these investors know what they are doing; know that they are speculating—taking chances with their money. They are not blind to the possibility of loss but are alive to the opportunity for gain. And they comprehend these things because they are men of average sense.

I see no justification for criticizing those who put their money into mining property or mining stocks in boom times nor those who encourage such investments along legitimate lines. There is certainly much greater opportunity for profit when speculation is rife and the stock market active than when things have settled down to a routine basis. As the Mining and Scientific Press so often insists, money put into mines is speculation, not investment. This being so, is it not good judgment to operate when speculation is most active, which is in boom times? No business or industry ever introduced was so organized that everyone could make profit from it all the time. In mining some lose and some win the same as in every other walk of life where money is risked for the purpose of making profit. The investing public understands this and only the few 'squeal' when the loss is legitimate. I can readily imagine the criticism which would be forthcoming were the development of the mining industry left to technical men. They would naturally turn the opportunity of acquiring every newly discovered mine to capitalists only. The public would be left out in the cold. The profits of mining would enrich only the few and prospecting would be discouraged because with a limited market buyers could control prices.

It seems to me that Mr. Curle's theories are not based on good reason. He rails at the laws of Nature which control these things and calls it immoral. If we look beneath the surface and judge the matter from all sides—from the human viewpoint of the common people as well as through technical eyes we will find that the laws of Nature in this case, as in all others, can be trusted to be logical and do the greatest good to the greatest number.

CLAUDE SACHS.

Denver, January 13.

Tube-Mill Lining, Slime-filters, and Patents.

The Editor:

Sir—About three years ago, I used an old boiler, 40 in. in diameter, to make a tube-mill for working cemented gravel, by putting six 4-in. angle-irons lengthwise inside, with the idea that the stones would jam between the angles and form a lining which would prevent wear on the boiler-shell. I made heads for each end, and the necessary trunnions, gear, etc., for running it with a horse-whim. Unfortunately, the high-grade gravel gave out by the time I had finished the mill, and it lies in the scrap-heap behind the shop.

During the winter of 1906, when considering the question of re-lining our tube-mill, I designed a lining, to be made in our local foundry, of hard iron (from worn out shoes and dies). This lining was designed in four segments, 4 in. wide, forming a circular arch fitting tight around the inside of the shell, with 16 partitions raised 3 in. and set lengthwise of the shell. These partitions were thickest at the inner end, so that the spaces between them were in the form of a dove-tail; the idea being that the pebbles would jam in these dove-tail spaces and form a pebble lining.

Sometime in the spring we had a very pleasant call from Charles E. Rhodes, general manager of the Waihi mine in New Zealand. We spoke of tube-mills and I made a rough sketch of my idea of this iron lining, and mentioned the fear I had of its working loose unless bolted in. He told me it would stay in without bolts, as their superintendent, Mr. Barry, had invented the same thing and was using it, only instead of waiting for the pebbles to fill the spaces he filled them with flinty quartz from the mine, held in cement.

On July 28, 1907, there appeared in the MINING AND SCIENTIFIC PRESS, a description and drawing, together with an abstract, of Mr. Barry's patent tube-mill lining. It is called 'honeycomb' evidently because the spaces in the castings are similar to the cells of the honeycomb. There is no date given for the patent, nor does it state the country from which it was issued. At the April meeting of the American Institute of Mining Engineers a paper was presented by E. G. Banks describing this same honeycomb lining.

On October 12, 1907, there appeared in the Mining and Scientific Press a description, with drawing and photograph, of a cast-iron lining for tube-mills in use at the El Oro mine in Mexico. In many ways it is similar to Barry's.

On November 23, 1907, in the same journal, under the head of 'Tube-Mill Lining,' an article was published describing a similar lining, with quotations

from a Mexican patent of February 22, 1907, granted to H. W. Hardinge.

On December 21, 1907, there appeared a letter from C. E. Rhodes referring to that of November 23, giving a photograph of the interior of the El Oro tube-mill and stating that "said liner has been in use in the El Oro mills for over two years."

On the same page is a letter from the Blaisdell Company, stating that reference to the U. S. Patent Office files will show that on June 13, 1906, Joseph Rodney Brown of Los Angeles (formerly of El Oro) applied for a patent on lining for grinding-mills, which was issued on August 27, 1907. Quotations of specifications from Brown's patent are given which would apply equally well to Barry's.

In May, 1907, Edwin Letts Oliver, who has charge of the cyanide work at the North Star mines, Grass Valley, constructed a small working model of a continuous slime-filter, which may be described as a revolving drum about two-thirds submerged in thickened slime. On the circumference was the ordinary filtering material and through the trunnions an arrangement to produce a partial vacuum or a pressure of air. On the outside of the filter a knife was fixed to scrape off the filtered material. This model did so well that work was immediately started for the construction of four drums 6 ft. wide and 6 ft. in diameter. Soon after the drawings were made, and the orders out for their construction, we had a visit from Jas. W. Neill, of Salt Lake, who was much interested in slime-filters. On seeing a sketch of our scheme he remarked that it would work all right, but we could not get a patent on it; the manufacturing chemists had been using exactly the same thing for fifteen or twenty years. As we cared nothing about the patent, it was enough for us to have the assurance that the machine would work.

Within a few weeks, on November 9, 1907, a letter was published in the Mining and Scientific Press from Askin M. Nicholas of Australia, accompanied by a drawing, stating that a U. S. patent had been granted him in February, 1899, for a slime-filter. The drawing showed a machine strikingly like the one we were constructing, and a month later, or December 7, the same paper published the patent specifications. Except in detail of construction, these patent specifications would equally well apply to our machine.

On August 24, 1907, there appeared on the front cover of The Engineering and Mining Journal, a large advertisement as a "Slime Announcement. Users and prospective users of **submerged suction** or **vacuum** or **submerged pressure filters,** are hereby informed and **warned** (black type copied) that the last three years litigation involving the well known Moore Filter Patents for treating slimes has come to an end, with the result that all rights, titles, interests and claims to these fundamental patents now rest in this corporation, of which Mr. George Moore (the inventor) is general manager. While this litigation has been pending, numerous installations under many different patent claims and titles (all clearly evident infringements) have been made and are in successful operation all over the world.—— The policy of this (new) corporation is to promptly suppress all infringements. For full particulars address the Moore Filter Company."

On the inside of the cover of the MINING AND SCIENTIFIC PRESS of January 11, 1908, is an advertisement of 'The Filtration of Slimes by the Butters Method.' Among other things it states, "We are working under valid American and Foreign Patents and shall protect our customers. The Butters Vacuum Filter Company."

The Kelly Patent Filter Press has been advertised for several months, and there is also the Burt and the Rapid. Grothe's great pressure-filter in Mexico—a splendid adaptation to conditions—I believe is not patented. In the patent announcements of your January 11 number, however, is a revolving filter which might be intended as a copy of Mr. Nicholas's, showing that the patent industry is still thriving.

In the matter of the tube-mill lining, it seems to me that Mr. Barry should have the honor of being the first to make an iron lining holding the pebbles for pebbles to grind on, though Mr. Brown, Mr Hardinge, and even I, may claim that our ideas were equally original, but they came later.

As to the filter, there can be no doubt that Mr. Nicholas was the first to use the submerged filter, with air to blow off the cake, for stamp-mill slime, but there were the manufacturing chemists using the same method for getting their soda ten years before. Mr. Moore, Mr. Butters, Mr. Kelly, and Mr. Oliver are undoubtedly entitled to originality of ideas, but they came later than Mr. Nicholas and most of them had original ideas in the details of the methods used and not as to the broad use of the process.

"Render unto Caesar the things which be Caesar's." Without brag or threats, the priority in these matters seems to rest with our modest friends, the alert engineers of Australia and New Zealand.

But amid the mass of patents and claims, the forgotten man is the mine manager, who, after all, is the man who makes success or failure for the patentees. He is in desperate trouble because his tailing is running down the gulch carrying gold, perhaps enough to make all the difference between profit and loss, and yet, when he reads the various patents—or the advertisements—he hesitates about putting in a slime-plant, lest the patent lawsuits worry him more than the loss in the tailing. Possibly it would be better business for the patentees and manufacturers to offer a few words of encouragement to the miner, and, instead of threats of suppression and dire calamities, use soft words to induce him to adopt their special machinery or process because it is better or cheaper than others. For it may occur to this miner, that tube-mills and vacuum-filters and pressure-filters were in use long before the present generation of inventors was born, and whereas patents may issue without thought and without number, he may conclude that "a dream cometh through the multitude of business, and a fool's voice is known by the multitude of words."

ARTHUR DE WINT FOOTE.

Grass Valley, California, January 17.

Analysis of Production of Two Great Copper Mines.

Written for the MINING AND SCIENTIFIC PRESS
By an Occasional Contributor.

CALUMET & HECLA.—In 10 years ending on April 30, 1907, this property produced 427,649 tons of fine copper.

Paid.....$52,500,000 dividends.
Invested ..... 9,878,000 in new property.

Total real earnings $62,378,000

Copper averaged.....15.45 cents per lb., or $309.00 per ton
Earnings " ..... 7.30 " " " " 146.00 " "

Cost ..... 8.15 " " " " $163.00 " "

The content of copper recovered from ore sent to mill diminished from 60 lb. per ton in 1897 to 41.7 lb. in 1907, but in 1907 one-sixth of the output came from the Osceola lode, which carries only 32 lb. per ton.

Cost of mining was in '97, '98, '99 .....$4.80 per ton
" " " " " '04, '05, '06 ..... 3.50 " "
Cost of copper remains the same.
Investments made by this company will prolong its life.

If Lake copper will continue to average 15¼ cents, which I think is likely, this mine ought to be able to pay $5,250,000 per annum, besides laying aside $1,000,000 per annum to add to its investment of $9,000,000 in contiguous territory. These investments ought to average a return of 10%, and in 10 years an enormous surplus could be built up, insuring the future of the property. See record below.

*Year.	Fine copper. Tons.	Price. Cents per lb.	Dividends.	Spent in purchase of new property.	Balance of assets.
1898.....	41,960	11 —12	$4,000,000	.....	$6,558,456
1899.....	43,879	12 —18½	7,000,000	.....	4,398,544
1900.....	44,548	18½—16	8,000,000	.....	4,260,858
1901.....	37,933	16½—17	6,500,000	(Fire)	2,168,130
1902.....	42,462	16⅜—11	4,000,000	.....	3,592,779
1903.....	42,216	11¼—15½	2,000,000	.....	6,557,023
1904.....	41,612	11¾—13¾	4,000,000	.....	6,583,038
1905.....	43,090	12½—15½	4,500,000	12,000 acres timber land $184,859	7,144,000
1906.....	43,652	15½—19	5,000,000	9,223,395	10,629,819
1907.....	46,297	18¼—26¼	7,500,000		7,028,942
Total...	427,649	15.45	$52,500,000	$9,408,254	.....

*The fiscal years end on April 30.

Investments and increase .....$ 9,878,740

Total earnings $62,378,710

1888—Milled 814,000 tons for 50,295,721 lb. Copper, 61½ lb. per ton.
1898—Costs $4.05 per ton.
1899—Milled 1,500,000 tons for 87,758,000 lb., or 58 lb. per ton. Cost this year was $5.65 per ton.
1900—Cost $4.71 per ton.
1905—Milled 75,000 tons of Osceola amygdaloid, yielding 22 lb. per ton.
1906—Milled in March 27,018 tons of Osceola amygdaloid.
1906—Milled 1,900,000 tons for 87,305,000 lb., or 45.9 lb. per ton.
1907—Milled 1,900,000 tons of Calumet conglomerate.
Also 320,000 tons Osceola amygdaloid for 6,892,518 lb.
Making 2,220,000 tons altogether for 92,584,000 lb., or 41.7 lb. per ton.
Total cost this year 8½ cents per lb. Value, 22½ cents. Profit, $13,120,000.

Memorandum of scheme for building up surplus: Money is being put into land and mining companies such as Osceola, Centennial, Allouez, etc., containing Kearsarge and Osceola lodes. These investments ought to yield 10% per annum. Beginning now with $9,000,000 invested the company can add $1,000,000 per annum from earnings of the present mine and let dividends accumulate. There will be in

1908	$9,000,000	+ $1,000,000	: interest	$10,900,000
1909	10,900,000	+ 1,000,000	"	12,990,009
1910	13,000,000	1,000,000	"	15,300,000
1911	15,300,000	1,000,000	"	17,850,000
1912	17,800,000	+ 1,000,000	"	20,600,000

1913 20,600,000, and so forth.

It is apparent, therefore, that in 1917 the company will have accumulated $10,000,000 surplus, yielding an income of $1,000,000 per annum. This is entirely feasible and probable, because by mining 3,500,000 tons of Kearsarge lode the output can be raised to 80,000,000 lb. at 10 cents per lb. The Calumet & Hecla has now 11,000 ft. on the Osceola lode, and 12,400 ft. on the Kearsarge lode opened up. If one-half of this ground can be mined to a depth of 3000 ft., it should produce at least 50,000,000 tons containing over 500,000 tons of copper at a profit of $100 per ton, or $50,000,000. The company controls the Allouez, Centennial, Osceola, and other mines, giving 10 miles more on these lodes, which should produce $125,000,000 more in profits if one-half can be mined.

ANACONDA.—This company has produced and earned as follows:

Year.	Copper. Tons.	Silver. Oz.	Gold. Oz.	Total value.	Cost per ton.	Earnings.
1896.....	52,518	5,308,000	18,300	.....	$9.43	$1,000,000
1897.....	66,182	5,935,837	20,380	.....	9.17	4,969,408
1898.....	62,209	5,074,036	18,000	$17 582,000	9.30	4,000,000
1899.....	53,907	3,750,000	14,000	18,400,000	9.50	6,000,000
1900.....	55,000	3,750,000	14,000	21,300,000	10.00	7,300,000
1901.....	50,925	3,600,000	14,000	19,200,000	10.00	5,300,000
1902.....	38,000	2,650,000	12,000	.....	.....	1,680,000
1903.....	46,750	3,200,000	20,000	.....	.....	2,000,000
1904 (18 mo.)....	60,900	4,000,000	22,000	18,800,000	8.50	4,350,000
1905.....	47,722	3,116,880	19,165	....	7.78	5,718,000
1906.....	47,482	2,979,908	15,984	.....	8.23	8,842,000
Total.....	582,595	43,364,000	188,000	.....	.....	$54,159,000

The earnings have gone as follows:

Dividends.....$33,000,000
Bonds paid off 3.600,000
Surplus..... 17,500,000 in cash and supplies.

Total.....$54,100,000

In this period of 12 years copper has averaged 14.1 cents per lb., silver 60c. per oz., and gold $20.67 per ounce. The value of the product therefore has been:

Copper.....$164,490,000 = 84.5% of total
Silver ..... 26,000,000 = 13.5% " "
Gold ..... 3,900,000 = 2.0% " "

Total.....$194,390.000 Profits, 28%

The mine has been able to produce copper at 10.17c. per lb., silver at 43.3c. per oz., and gold at $14.91 per ounce.

In 1906 copper accounted for 90% of the value; silver, 8½%, and gold, 1½%. On this basis copper cost 11.8c. per lb., silver 35c., and gold $13.50 per ounce. This rise in the cost of copper has taken place in spite of a decrease in the cost per ton of production from $9.43 in 1896 to $8.23 in 1906. It is caused by a diminution of the value of the ore on average prices as follows:

1895-6. Value, $15.93. Cost, $9.30. Margin, $6.63..... { Copper ....14.1c. Silver .....60.0c.
1905-6. " 10.54. " 8.01. " 2.53..... { Gold $20.67

It appears, therefore, that the continuance of this process of diminishing value will in six years more extinguish the margin of profit. On this basis the dividends to be expected from the property would be as follows:

Surplus.....$18,000,000
Earnings.. 12,500,000

Total $30,500,000
Less ..... 5,700.000 already paid.

Total $24,800,000

} At average prices.

I believe that better results can be obtained by diminishing the tonnage and maintaining the grade as it stands at present. By diminishing the tonnage by 5% each year the mine can last 20 years, and produce 13,200,000 tons at a profit of $33,000,000; add surplus (less dividends paid), $12,300,000; making a total of $45,300,000.

Discounting this until it is paid would give a present value of $30,000,000. This is the best that can be expected.

BOLIVIA has long been favorably known as a source of supply of bismuth, the metal occurring with tin, gold, and silver ores, especially at Tasna and Chorolque. In France bismuth has been discovered in quantity with wolfram, pyrite, and phosphatic minerals. The Cornwall, England, tin and copper mines produce it in small quantity.

The Great Gold Mines—II.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

(*Continued From Page 13.*)

Outside of the five mining districts mentioned in the preceding paragraphs, there are a number of localities made famous and important by the production of individual mines. These include four of the biggest: the Waihi, the Mt. Morgan, the Homestake, and the Goldfield Consolidated.

The Waihi, the great gold mine of New Zealand, is in the Hauraki district of the North Island. During the calendar year 1906 this mine produced 328,866 tons, yielding 168,012 oz. gold and 1,133,062 oz. silver, together worth $4,001,250, or $12.23 per ton. The profit for the year was $2,435,056, from which dividends and bonus were paid amounting to $1,926,633. From its inception (in 1893) to 1906 this mine had produced £5,355,254 from 1,921,670 tons of ore, and £2,296,548 had been distributed in dividends, besides the £146,160 paid in the form of income tax, the last being a direct saving to the shareholders. The reserves are estimated at 1,029,658 tons, or a supply for three years ahead. The main lode, called the Martha, averages 90 ft. in width for a length of 1400 ft. and has been developed to a depth of 800 ft. It is only one of a series of interlacing veins. The mine is wet; two Cornish pumps raise about 700,000,000 gal. per annum. At the end of 1906 the main shaft was only 856 ft. deep; it is now just below the 1000-ft. mark.

The Mount Morgan is the greatest gold mine of modern days; it has yielded (up to May 31, 1907) no less than 3,079,695 oz., worth $60,961,087, out of which $32,757,705 has been paid in dividends. As the company was organized in 1886, this record covers twenty-one years. During the last fiscal year the total revenue was $1,531,991, of which $1,663,725 was profit. Originally a high-grade gold mine, Mt. Morgan has proved to be an immense gold-bearing gossan capping a mass of gold-bearing copper pyrite. In the year ending on May 31, 1907, the extraction of oxidized ore from the big open-cut gave 120,373 tons, yielding 35,313 oz. gold or an average of 5.86 dwt. per ton. Since the inception of the company 2,049,532 tons of oxidized ore has been extracted. It has been worked to a depth of 315 ft., at which level the sulphide ore makes its appearance. Of sulphide ore, 115,166 tons were mined during the year, the yield being 61,370 oz., or an average of 10.6 dwt. per ton. From this ore, 361 tons of copper were extracted. The total yield included 97,923 oz. gold and 361 tons of copper precipitate from the chlorination works, besides 3723 tons of copper and 47,215 oz. gold by smelting, that is, a grand total of 145,139 oz. gold and 4087 tons of copper, giving Mt. Morgan high rank as a producer of either one or both of the metals. Of the 600,732 tons of material removed during the year, 265,779 tons were rejected as waste and 334,953 tons went to the reduction works. The average, therefore, was 8.7 dwt. gold and 1.22% copper. The deepest level is at 850 ft. The reserves are estimated at about 2,500,000 tons, from which a profit of $12,500,000 should be made.

The Homestake mine was crippled in 1907 by a fire that broke out above the 600-ft. level on March 25. In order to extinguish the fire, it became necessary to flood the mine, and stop production. It was not until July that all the stamps were dropping again. Hence the record of production in the last fiscal year does not do justice to this great mining enterprise. Moreover, $305,421 was expended on the new slime plant, for this company follows the sensible custom of debiting all cost of equipment to revenue account. The new slime plant is a great success and has nearly doubled the operating profit. At the present time the Homestake is yielding $500,000 per month, of which $200,000 is profit, so the figures for the current year will be highly satisfactory.

PRINCIPAL MINES IN AMERICA AND ASIA.

*Estimated. See detailed description.

Nevada is producing gold at a great rate, but the methods of operation do not lend themselves readily to the detailed tabulation of results. Owing to the State tax on profits, the companies are chary of publicity. Moreover, between the stock-jobbing schemes of those in control and the ore-stealing activities of those whom they employ, the statistician is driven to despair, for no trustworthy data are available. However, the consolidation of mines at Goldfield, under the name of the Goldfield Consolidated Mines Co., has published its annual report recently, and amid a maze of jumbled accounts there is enough information to prove that this property in Nevada was the most productive gold mine in the world in 1907. The total output for the fiscal year ending on October 30, 1907, was 31,338 tons, having a gross value of $6,296,476, or the magnificent average of $200, that is, about 10 oz. gold per ton. The total profit to the company was only $1,760,358, or 26% of the gross output, but to the company's profit must be added that of the lessees, estimated at $2,000,000, so that the mine is credited with a total profit of $3,760,358. Furthermore, fully $1,000,000 worth of ore was stolen, on which the thieves made not more than 10% profit, the rest being divided among the middlemen and ore-buyers; but this item cannot be credited to the mine. It is clean loss, the penalty of excessive richness

and a labor situation without parallel. This wonderful mine has yielded fully $15,250,000 in the four years since the discovery of ore in November, 1903, although the bulk of the output has been made since April, 1906, when the Mohawk bonanza was uncovered. Up to date the following is the estimated yield of the component mines:

Mohawk	$ 9,850,000
Jumbo	1,625,000
Red Top	500,000
Combination	3,000,000
January	275,000
Total	$15,250,000

Of this total, about $7,000,000 has been profit to the company and the lessees. The last shipment (one carload) of ore made from the Hayes-Monnette lease (in January 1907) weighed 48 tons, averaging $12,230 per ton or $6 per pound of ore. The check from the Selby Smelting & Lead Co. amounted to $574,958 and the express charges (that is, transport and insurance) were $8810 for the carload. The ore was in sacks weighing 632 lb. apiece. Up to the date of consolidation (in November 1906), the Mohawk shipped 34,797 tons having a gross value of $4,075,919, on which the royalty paid to the owners of the mine was $705,469. The orebody was discovered in April 1906 and prolific production started in August, not less than $5,000,000 worth of ore being extracted (though not all of it was shipped) in 106 days.

The consolidated mines are now under experienced management and future reports are likely to be more luminous and less voluminous. As to ore reserves, no accurate information is available. In the prospectus, issued on November 21, 1906, the "future production" is estimated as "at least $30,000,000", while in the report for October 31, 1907, the ore developed is stated to amount to 1,000,000 tons, averaging $25 per ton, of which $17 "should be profit." As the bottom workings at 500 ft. are in rich ore, the future of this mine looks brilliant. Profits will be increased when the mill is built; this will contain 100 stamps and treat 500 tons per day at an estimated cost of about $2 per ton. Up to the present the Goldfield Consolidated has been a gold mine to the smelters, the railroads, and the ore thieves, henceforth it should prove a treasury to its owners.

While Cripple Creek is still the chief goldfield in Colorado, the leading mines are in the southwestern portions of the State, between the towns of Ouray and Telluride. The Camp Bird is the most productive and next to it comes the Tomboy. The Tomboy Gold Mines is a company controlled by the Exploration Co. of London. It affords a good example of an enterprise that started with one mine which proved disappointing, and then acquired a neighboring property, which exceeded expectations. The old Tomboy mine was a fizzle, but the Argentine, which was bought as a prospect and developed into a large mine, has proved a winner. In the year ending on June 30, 1907, the output was 110,597 tons, yielding $1,295,123, of which $778,735 was profit, permitting the payment of $545,625 in dividends. The ore reserves are estimated at 408,000 tons and the development has reached a depth of 2100 ft. below the outcrop.

Owing to the snowslide and fire that destroyed the mill of the Camp Bird company in March 1906, the production for that year was interrupted. The new 60-stamp mill was rebuilt without loss of time at an expense of $177,807. As the fiscal year of this company ended on April 30, 1907, the record covers the operation of the mill during 181 days, beginning on November 1, 1906. During that time 38,295 tons were treated, yielding $1,339,864, of which $44,198 was silver and $22,114 lead and the remainder gold. In order to redress the loss due to the destruction of the mill and the period of inactivity, the policy adopted was to extract the higher grade ore already lying broken in the stopes. Of this class of ore 25,809 tons were sent to the mill, and 13,731 of freshly broken ore. On April 30, 1907, there were 112,000 tons of broken ore in the stopes and chutes, and 89,000 tons blocked out, making a total of 201,000 tons, estimated to yield a profit of $3,500,000. In the last five years the Camp Bird has yielded $9,494,635, of which $6,324,270 has been profit. The dividends represent 95% on the capital of the company. But the future of this splendid mine does not promise a continuance of its present prosperity, for exploratory work in depth has led to the discovery only of irregular patches of pay-ore, the best results during the last three or four years being in the workings above the upper adit.

The Alaska-Treadwell, on Douglas Island, Alaska, has been crippled during the past year by lack of fuel. The figures in the tabulated statement are for the year ending May 31, 1907, but they are not a fair average. During the previous year the output was 888,411 tons, yielding $1,902,455, of which $925,193 was profit. The yield per ton was $2.141; of this $1.074 was free gold obtained by amalgamation and $1.067 was extracted from concentrate by chlorination. Up to May 31, 1907, the total yield of the mine was 8,485,085 tons, yielding $20,735,788, of which $9,861,439 was profit. The yield has included $12,524,507 from free gold and $8,211,281 from concentrate. The ore reserves are estimated at 5,000,000 tons.

The principal gold mine in Utah is the Mercur, which has paid dividends of $1,205,000 since the consolidation of the old Mercur and De La Mar companies in 1900, and $3,385,313 altogether. For the year ending on June 30, 1907, the production was 245,169 tons, yielding $642,844, from which no profit was earned.

The North Star mine at Grass Valley is the basis for one of the most satisfactory mining enterprises ever started in California, and it has been a highly profitable mine to various owners during the past 57 years. From 1850 to 1884 the North Star produced $2,500,000. The present undertaking, under the direction of James D. Hague, is an example of a well managed and highly successful mining company. From May, 1884, to the end of 1906, the total production has been 487,763 tons, yielding $7,477,940, or an average of $15.33 per ton, from which the operating profit has been $2,928,473, permitting dividends to be paid to the amount of $1,286,988. In the year ending on December 31, 1906, the North Star Mines Co. treated 84,672 tons of ore, yielding $826,326, with a profit of $311,059. For 1907 it is estimated that the output was 80,000 tons, yielding $925,000, from which dividends amounting to $250,000 will be paid, as was the case last year. The deepest workings are at 4700 ft. on the dip of the vein.

Data relating to California mines are difficult to obtain owing to a policy of secrecy, due in part to labor troubles and in part to the influence of the stock market. The North Star Mines Co. is a pleasant exception, as the preceding paragraph indicates. Having a first-rate management and a profitable enterprise, the relations of the company are as harmonious with the employees as they are with the shareholders. Another important mine that is doing well is the Kennedy, at Jackson, on the Mother Lode, but, while knowing the output and profit made during 1907, we are requested to withhold the information. The most profitable gold mines in California are the Yuba Consolidated, at Marysville, and the Oroville Dredging, at Oroville. Oroville Dredging Ltd., a London company, produced $705,839 for the year ending July 31, 1906, and of this amount $355,705 was profit; in the six months following (that is, up to January 31, 1907) the yield was $473,108 and the profit

The Destruction of the Camp Bird Mill in March, 1906.

The Esperanza Mine, El Oro, Mexico.

$267,000. Later figures are not obtainable, but they are at least as good. Concerning Yuba Consolidated, we can only say that the output was $1,500,000 and the profit in excess of $1,000,000 for the calendar year 1907. This is the only gold mine in California yielding either $1,000,000 profit or $1,000,000 gross during 1907 and it promises to be a magnificent enterprise. The two leading gold mines of California are dredging undertakings, and this fact emphasizes the relative importance of this branch of mining.

The Oriental Consolidated, in the Wunsan district of Korea, is an important gold mine, for up to June, 1907, it had produced 1,337,519 tons of ore containing $9,116,227. During the last year or two the profits have been less, but the new cyanide mills and the healthy development of the mines give promise of better results in the present fiscal period. In the year ending on June 30, 1907, this mine produced 231,827 tons, containing gold worth $1,232,263 and made an operating profit of $364,696. The value per ton was $5.31, the extraction $3.90, the costs were $2.48, and the profits $1.42, the last being decreased by construction expenses and development of outside mines to 90 cents per ton. This mine is held under a concession granted to a group of New York financiers, and it is under the experienced general management of H. C. Perkins.

Butters Salvador, in the State mentioned in the last part of the name and under the direction of the energetic metallurgist indicated by the first part, is the most productive gold mine in Central America. Up to July 1, 1907, the output has been 80,962 tons, yielding $3,808,826. The ore reserves are estimated at 62,963 tons, containing $4,087,000. The maximum depth of the workings is 628 ft. The ore contains copper and this makes the cyanidation difficult. After being roasted, the ore is crushed in Krupp ball-mills and then cyanided. The consumption of cyanide is 8 to 10 lb. per ton of ore. Copper is saved at the rate of 1½ tons per month.

In Brazil, the St. John del Rey is a grand old mine that has been worked by the same company since 1834. A fire and the caving of the big stopes have crippled production during recent years. The incline shaft is over a mile long and the vertical depth is 4000 ft. During the half-year ending on August 31, 1907, this mine produced 76,690 tons, yielding $787,271, of which $181,948 was profit.

The leading gold mine of New South Wales and the only one of the first rank is the Mt. Boppy, in the Cobar district and near celebrated copper deposits. In 1906 the output was 72,976 tons, yielding $617,218, of which $306,167 was profit. Down to 400 ft. this mine has now produced $2,215,670, from which $993,315 has been distributed in dividends.

Two mines in West Africa are worthy of mention. In the year ending on June 30, 1907, the Abosso produced 36,881 tons, yielding $542,475, of which $214,956 was profit. The reserves amount to 187,831 tons, the average assay being 17.25 dwt. per ton. The Ashanti Goldfields during the same period produced 48,610 tons, yielding $914,361, of which $394,906 was profit. This company is to be reorganized. The bottom of the mine (at the 6th level) is poor and the outlook is bad.

In the Transvaal there are no big mines outside of the Rand district, unless it be the Sheba, at Barberton, which was a rich mine before the war. Up to 1907, the Sheba had produced 872,341 tons, yielding 638,975 oz. or about $12,500,000. For the year ending on June 30, the output was 66,250 tons, yielding gold worth $677,220. The Sheba paid over $3,500,000 in dividends in the days of its prosperity.

In point of magnitude of operations, the Homestake is first, for it keeps 1000 stamps busy, crushing 4000 tons per day. Next comes the Alaska-Treadwell with 540 stamps, in two mill-buildings containing 240 and 300 stamps respectively, and crushing altogether 2840 tons per day. The loss of quicksilver is given as 32.47% in one mill and 35.19% in the other. In South Africa the biggest milling plant is that of the Simmer & Jack, with 360 stamps, of which 320 are in use, the crushing capacity being 2070 tons per day. The Robinson has 300 stamps, and 13 other companies on the Rand have mills of 200 stamps or more. The Waihi has 330 stamps, the average number at work being 317, with an average duty of 3.5 per stamp or 1110 tons per diem. The work of reduction is aided by 5 tube-mills, and it should be added that in South Africa also tube-mills are steadily raising the duty of the stamps.

BRIQUETTING PLANT IN ARIZONA.—A briquetting plant was put in operation in September, 1905, by the Arizona Copper Co., Ltd., at Clifton, Ariz. It was installed for the purpose of utilizing coke-breeze, for securing greater efficiency from the Gallup slack coal, and for obtaining a fuel that would not materially deteriorate under storage. In the briquetting of the coke-fine a profit of about $4 per ton is made in the conversion of a formerly wasted material into good fuel. Briquetting the Gallup slack coal was not advantageous economically, because the expense brought the cost about the same as that of the lump coal obtained from the same source. The real profit in briquetting this coal is in the superiority of the product for stocking purposes, as it stands weathering perfectly and is not liable to spontaneous combustion. In the making of the briquettes 92% of the coal is mixed with 8% of California asphaltic pitch and compressed. The briquettes are rectangular in shape and weigh about 4 lb. each. The capacity of the plant is 25 tons per 10 hours. About 300 tons were produced in the experimental runs made in 1905. During the first six months of 1906, the plant produced 690 short tons of a total value of $1830, or an average of $7 per ton. This included briquettes made from coke-breeze. The coal briquettes have been found to burn freely and satisfactorily under locomotive and stationary boilers.

COPPER IN THE PHILIPPINE ISLANDS.—The best-known occurrence of copper in the Philippine Islands is in the Mancayan-Suyoc mineral region of the province of Lepanto. Sulphide ores predominate and were extensively worked in 1850 and later. Between 1864 and 1874, a Spanish-Filipino company produced 1100 metric tons of copper in the vicinity of Mancayan. An American syndicate is now developing a number of new claims. In the Suyoc district several copper deposits are being developed. The ores consist of auriferous tetrahedrite, tennanite, enargite, and luzonite; the Government samples showed, by assay, 9.7 to 39.9% copper and 85c. to $4.75 gold per ton. Veins of refractory gold-copper ore occur in the Buld River district. In the foothills of the northern Zambales range, near Salasa, copper veins rich in gold are being developed. The Bataugas province contains copper in the Loboo mountains. The veins are of two systems and are in dioritic rock. They are 6 in. to 2 ft. wide and carry bornite, chalcopyrite, tenorite, cuprite, chalcocite, malachite, and azurite; also, some gold and silver. The gangue is quartz. However, copper has not yet attracted the attention which has hitherto been given to coal and gold in the islands.

ONLY two per cent of people are left-handed. Right-handedness is due to the localization of the cerebral centre of the intellect in the left-half brain.

National Mining Bureau.

In our issue of January 18 we published the text of a bill before the Congress of the United States, the purpose of which is to create a Mining Bureau under the Department of the Interior. The subject is of great interest to all those engaged in mining, directly or indirectly, so we need not apologize for giving herewith a copy of the letter addressed by Mr. George Otis Smith, Director of the Geological Survey, to the Secretary of the Interior. For the letter we are indebted to the Director himself, who judged rightly that we would be glad to have the opportunity of affording our readers a chance to listen to his argument in behalf of the Survey. Our own views need not be re-iterated on this occasion; they will be found in the MINING AND SCIENTIFIC PRESS of January 18, December 7, and November 29. The Director's letter begins by acknowledging the Secretary's request for "an expression of opinion relative to the desirability of a more extensive recognition of the mining industry by Government investigations." Thereupon the Director of the Survey says:

The beginnings of Federal investigation of mineral resources are to be traced back to the early part of the last century, when Lewis and Clark were instructed to pay special attention to the geology and mineral resources during their exploration work. The explorations and surveys that were continued during the first half of the nineteenth century were a further recognition of the duty the Federal Government owed the people in making known the resources of the great unexplored western half of the continent. These explorations were particularly actively pushed after the discovery of gold had focussed public attention on the mineral wealth of the trans-Mississippi region. While the results of these various surveys were of inestimable value to the development of the mining interests of the regions that they covered, yet there was lack of coordination and an absence of a comprehensive plan covering the entire field. Moreover, it had not yet been recognized as the province of the Federal Government to investigate the resources of the entire national domain and not simply those of the public lands.

In 1866 a more direct attempt was made to aid the mining industries by an appropriation which authorized the Secretary of the Treasury to "collect reliable statistical information concerning the gold and silver mines of the Western States and Territories." Though this investigation received inadequate financial support, yet the results obtained by Dr. R. W. Raymond were of the utmost value to the mining interests.

When, in 1879, the U. S. Geological Survey was authorized by Congress, all other Federal surveys of a similar character were abolished, and the office of Commissioner of Mineral Statistics under the Treasury Department also lapsed. The organic law provided that the Director of the Geological Survey "shall have the direction of the Geological Survey and the classification of public lands and examination of the geological structure, mineral resources, and products of the national domain." It is to be noted that this authorization, besides providing for geologic investigation also directly authorizes the study of mineral resources and *products* of the national domain. It would appear therefore that Congress believed it was providing for all phases of work properly belonging to a mining bureau. In any event, the first Director, Clarence King, regarded the law as a justification for him to undertake investigations of not only a geologic character, including examinations of orebodies, but also the study of mining and metallurgical methods. This fact is clearly shown in the summary of his first report, wherein he provides for the following publications, based on investigations inaugurated by him:

Geology and Mining Industry of Leadville, Colorado.

Geology of the Eureka Mining District.

The Copper Rocks of Lake Superior.

History of the Comstock Mine.

The Comstock Lode.

Mechanical Appliances Used in Mining and Milling on the Comstock Lode.

Coal of the United States.

Iron in the United States.

The Precious Metals.

Lesser Metals and General Mineral Resources.

The Uinkatet Plateau.

Lake Bonneville.

Dinocerata.

Out of these 13 publications it will be noted that 10 were to be devoted to the subjects of applied geology and technology, and it is evident, therefore, that King regarded the U. S. Geological Survey as being charged with the duty of directly serving the mining industry of the country. Unfortunately, the broad plan of investigation which King had outlined could not be carried out because of the inadequacy of the funds provided for the work. It appears that King's successor, Major Powell, on this account established as his policy the plan of carrying on the fundamental geologic work which he knew was absolutely essential as a preliminary to the solving of the problems connected with economic geology. Major Powell's success, therefore, as an administrator of scientific work was due to the fact that he laid the plans on broad scientific lines. He also organized a Division of Statistics and Technology, but, unfortunately again, this work received so little support that not much original investigation could be carried on.

In 1894, when Mr. Walcott took the leadership of the Geological Survey, he was quick to realize that the time had come when more attention should be given to the immediate wants of mining interests. His plan, therefore, involved investigation of nearly every phase of the mineral resources of the country, though at the same time he did not curtail the study of the larger geologic problems. Probably the most important feature of Mr. Walcott's administration from the standpoint of mining was improvement in methods of collection of statistical data, and by his advice this work was extended to include that of

the precious metals. Mr. Walcott went back to Clarence King's original plan of placing the supervision of the collection of mineral statistics in the hands of the expert economic geologists, as being the only men who could have a comprehension of the resources to be considered. As a result, the statistical work of the Survey is on the highest plane and is frequently quoted in this country and abroad as an example of what all other countries should inaugurate. Under Mr. Walcott, too, technologic investigations were inaugurated; but these were limited by the appropriations to definite fields.

Under both Powell and Walcott the development of topographic mapping of mining districts was actively pushed. This phase of the Survey work, like the investigations of geologic problems, is of fundamental importance to all economic work.

To summarize briefly the items in the work of the Geological Survey which bear directly on the mining industry:

1. Annual reports showing the mineral production of the various mining districts and the various mineral products and also those that summarize the mining development throughout the country. These reports have the most direct bearing on mining, but they could only be prepared because of the extensive investigations which had preceded them during the existence of the Survey.

2. Monographic treatises on particular mining districts or particular kinds of mineral deposits.

3. Geologic maps, which must form the basis of the study of the distribution of mineral products. An area of 138,536 square miles is already covered by these maps.

4. Reports on water resources, many of which pertain to power available for mining.

5. Topographic base maps for the use of mine operators, mining engineers, and prospectors, as well as for the use in the study of geology.

6. Technologic studies of mineral products. This so far has been practically limited to the investigation of the utilization of the mineral fuels and building material.

The Survey investigations relating to mining have all been approached from the standpoint of the scientist, a policy believed to be in accord with the spirit of the Congressional enactment establishing this branch of the public service. The present importance of economic or applied geology is to a large extent the result of the Survey's activity and the practical value of its contributions has won world-wide recognition. In the present organization of the Survey, two divisions of the Geologic Branch and one of the Technologic Branch are devoted exclusively to the mining industry, while a large part of the work of the Technologic Branch and of the Division of Geology and Paleontology and of Chemical and Physical Research in the Geologic Branch contribute directly to the aid of the mining industry of the country, not to mention the indirect but important service rendered by the Water Resources Branch and the Structural Materials Division of the Technologic Branch. It is worthy of notice that the Divisions of Mining and Mineral Resources and of Alaskan Mineral Resources are at present keeping in close touch with the mining industry. Through their work, the Survey is in possession of complete lists of the mines of the United States and also nearly complete lists of Alaskan mines and from these mines the division receives statements of annual production. On this basis summaries of the state of the mining industry at the close of each year are prepared and published. The importance of this statistical work has been clearly stated by Dr. R. W. Raymond, formerly Commissioner of Mineral Statistics, and an eminent authority among mining engineers, who, moreover, has recognized the Survey as the successor to the investigations and publications inaugurated by him.

The Geologic and Water Resources Branches have for several years been conducting a joint investigation of the débris problem, which had never before been adequately considered on a scientific basis. The technologic work relating to mineral fuels has been authorized by appropriation items, yet this work undertaken under Director Walcott differed little in scope from investigations planned by Director King, but necessarily for a long time neglected in the absence of any specific appropriation by Congress.

While it might be held that the organic authority granted the Director to examine the geologic structure, mineral resources and products of the national domain is sufficient for any extension of the mining work, yet in view of the present well warranted demand for expansion of such mining work, it seems advisable to secure from Congress specific authorization for these investigations. However, before considering the best means of providing for the new work in aid of the mining industry it is necessary to mention the lines along which extension of Federal work is requested. Especially is this important since there does not appear to be any consensus of opinion as to exactly what should be the scope of a new bureau or what shall be its relations to the existing organization. In fact, some of those who have advocated further recognition of the mining interests have been unfamiliar with the work of the Geological Survey and have not realized how closely its activities were related to the mining field. First among the kinds of mining work for which there has for many years been a steadily increasing demand is the study of ore and mineral deposits. The work of the Geological Survey in the interests of the prospector and mining engineer has been appreciated throughout the mining communities. Two only of many cases of official recognition of the value of the Survey's work need be cited in this connection. The Legislature of Pennsylvania, the State which stands first in the value of its mineral products, provides for co-operation in geologic work with the Federal survey, entrusting to the latter the expenditure of State money in the investigation and mapping of its mineral resources. The General Assembly of the State of Colorado has twice, at least, expressed its appreciation of the Geological Survey. In 1879 in a memorial to Congress, presented by Senator Wolcott, this Assembly petitioned Congress "to make

generous provision for that branch of the United States Geological Survey which is engaged directly in examining metalliferous districts of the States and Territories'' and urged speedy publication of the results.

Ten years ago the statistics of mineral production collected by the Geological Survey were regarded as incomplete in that those of gold and silver were not included, and a public demand was made for the inclusion of these statistics in the annual report of the mineral resources of the country. At present the collection of these has been authorized by Congress. The Survey's policy that the mining industry of the country is stimulated and guided by the distribution on the part of the Government of statistical and technical information has commended itself to the mining public generally and it has been well said that the distribution of knowledge is the one governmental activity which carries the largest probability of general benefit. Many authorities have emphasized the necessity of entrusting its statistical work to geologists, who not only can properly classify each year's production but can measure the amount of the nation's reserve of mineral wealth.

There is another field in which the demand is actuated by real needs and this includes investigation into the methods of mining and metallurgy, especially with reference to the prevention of accidents and the better utilization of mineral products. Investigations already made along these lines by the Geological Survey show that this work lies well within the province of the Federal Government. Yet a large part of the field is as yet unoccupied and would include reports on the newest development in the various branches of the art and short summaries of mining and metallurgical methods for the use of prospectors and operators.

Many advocates for a Department or Bureau of Mines mention the need of Federal inspection of mines. The inspection of mines except in the Territories and the district of Alaska belongs essentially to the police regulations of the State authorities, so that in the absence of any Federal law regulating the operations of mines there is no field for a system of mine inspection, regulation, and supervision, except within the territories where this is already performed by inspectors who report to the Geological Survey. However, the publication of the results of investigations on this subject of mining methods and the nature of explosions in their relation to gas and dust in coal mines, the character of explosives, and other subjects affecting the safety of mine employees and of mining property constitute a duty which the Federal Government might, and should, assume through a scientific bureau.

The investigations of labor conditions in the mining industry and of the capitalization of mining corporations are functions delegated to mining bureaus in some foreign countries; but these are subjects that in the United States plainly belong to the appropriate bureaus of the Department of Commerce and Labor.

The expressed desire for free assays and analyses and for examinations of private mining property is complimentary to the character of the work performed by the various scientific bureaus of the Federal Government; but, in my opinion, this demand is for private and not public work and can more properly be met by the private assayor and mining engineer as well as by the State mining bureaus and schools of mines, leaving for investigation by the Federal Government only the larger inter-state and Federal problems that are basal in character and important in the whole mineral industry. The investigations already carried on by the Geological Survey are of this type.

To recapitulate: Of these functions mentioned by advocates of extension of Federal activity, two, namely, the study of mineral deposits and the collection of production statistics have been performed by the Geological Survey since its organization and the extent of such work has been limited only by the amount of public money appropriated; two others, namely, the investigation of mining technology and the supervision of Federal mine inspection in the Territories are now definitely provided for in the Survey organization—the scope of technologic work being as broad as is authorized by the terms of the appropriation; and of the remaining two, the investigation of labor and corporation conditions belongs to another Department, while the work of assays and examination of private mining property is more properly the privilege of men in professional practice or of a State bureau than it is the duty of a Federal bureau.

To meet the actual needs of the industry, the time is opportune for the enactment of well considered legislation and I submit herewith the draft of a resolution which in the opinion of myself and associates in the Survey is adapted to accomplish the desired end. My purpose is to suggest legislation that will adequately provide for an increase in the mining work by the Federal Government without duplicating that already authorized. Some plans already presented for a Bureau of Mines have contemplated taking over much or nearly all the work of the Geological Survey; others have confined the proposed Mining Bureau's activities to the more purely technologic problems together with the statistical work.

It appears to me that there is only one true line of cleavage between these subjects, and this lies between the pure technology and those matters relating to distribution, occurrence, origin, and production of mineral deposits. Those who advocate the turning over to another organization the statistical work of the Survey have little comprehension of the true character of these investigations. As now carried on, this work embraces not only the tabulating of the statistical information, but also the discussion of the source of the materials themselves.

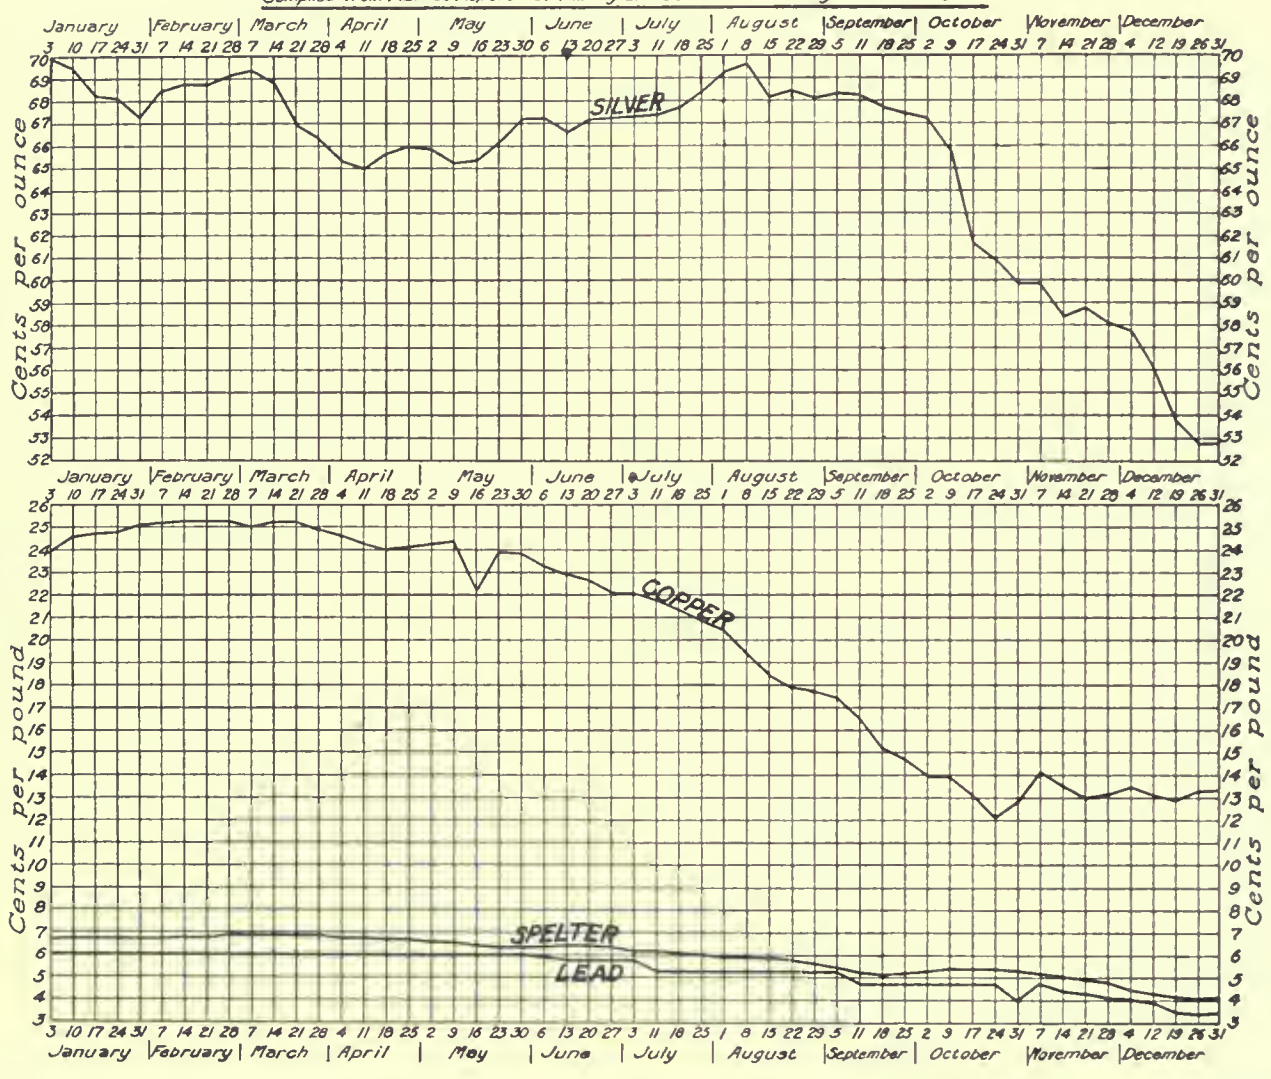
On the basis of the historic development and present status of Federal work in aid of the mining industry of the United States, the limitation of the function of any organization independent of the Survey to strictly technologic work is in my opinion absolutely essential if duplication of work and rivalry are to be avoided.

SELENIUM, one of the rare and little known elements, is closely related in many ways to tellurium and sulphur, with both of which it often occurs in nature. Recently it has obtained some prominence from its use in various forms of electrical apparatus, where advantage is taken of its peculiar property of being almost a non-conductor of electricity in the dark, while under the influence of light its conductivity immediately becomes greatly increased. This characteristic has led to its use in instruments designed for lighting and extinguishing gas buoys automatically; for guiding and exploding torpedoes by a ray of light; for telephoning along a ray of light; for transmitting sounds and photographs or other pictures to a distance by means of a telephone or telegraph wire; and for measuring the quantity of Roentgen rays in therapeutic applications. A general or practical use of any of these instruments would result in an increased demand for selenium. At present the metal is variously quoted at from $13.33 per kilogram (2.2046 lb.) to $2 per oz., as there is no steady market, and the prices vary with different dealers. No selenium is known to be produced commercially in this country, but during 1906 one copper refinery made some in an experimental way, and it is possible that it was produced at other refineries also. At this refinery the selenium was obtained from the anode slimes or mud, where it is left with gold, silver, and other residues in the electrolytic refining of copper. Minerals containing selenium are of rare occurrence in the United States, but a demand for the metal could probably be supplied by utilizing the small quantities found in the copper refinery slimes.

THE HUM OF INDUSTRY.—One has never really heard it until he has stood in the growing hull of a 600-ft. long steel ship and heard a hundred pneumatic riveters at work. Sign language only is used there. Compressed air is the magician. Even the rivet boys are not allowed to lose time pumping bellows at their forges; a tiny stream of compressed air supplies them with forced draught. If a rivet is countersunk, the rough surplus projecting is not slowly smoothed away by man power and hammers and chisels; a pneumatic tool does it in a few seconds. If an emergency requires a rivet hole which has not been punched, a pneumatic drill does the work as deftly as a cook trims a pie crust.—*Gunter's Magazine.*

Graphic representation of average weekly prices of Silver, Copper, Spelter and Lead during 1907

Compiled from Market Reports of Mining and Scientific Press by R. F. Morton, C.E.



GOLD has been found about 25 miles north of Zamboanga, in Mindanao, P. I. It occurs in a sticky yellow clay, which is a weathered portion of schist, but apparently it is found only in very moderate quantity. Its original home was the quartz stringers in the schist. No veins large enough to work have yet been located. The only apparent profitable method of working such placer ground would be by hydraulic means, and as the city of Zamboanga is at present, and probably will for some time to come be dependent upon this river for its water supply, there would undoubtedly be serious objections to this method. Three or four Zamboanga prospectors worked very industriously in this region for over a year sluicing, but apparently did not get a great deal to repay them. For some time to come all thought of accomplishing much in the interior of Zamboanga peninsula will have to be given up, owing to absolute lack of roads.

Drills for Stoping.

Written for the MINING AND SCIENTIFIC PRESS
By ALGERNON DEL MAR.

From observation in California, and particularly in the desert country of the South, where gasoline is readily obtainable at a reasonable cost as compared with other fuel, I venture to say that the application of the small air-hammer stoping drill has not been fully appreciated. I do not mean the hand-drill of the Hardsoeg or Iler type, which is deservedly in favor, but such devices as the Smucker, Waugh, and Sinclair drills, in which the air-pressure keeps the drill up to its work and where the operator is only required to hold or turn the drill. The hand-hammer drills have limitations of usefulness just as the 2¾, 3¼, and 3½-in. reciprocating drills, the former being of use for short water-holes, the latter for hard ground and wide stopes or big headings. Between these extremes comes the class of workings in which the ground is of average hardness, permitting stopes 3 to 6 feet wide, with walls either hard and easily sustained or of a crumbling nature. Under ordinary conditions, whether the walls will stand heavy shooting or not, I believe the small air-hammer drill will outclass a drill of the 2¼-in. reciprocating type in almost any kind of rock and in the case of crumbling walls or walls easily fractured, and therefore requiring excessive timbering, this class of drill will remain as the only kind of economic value outside of hand work, which it will discount in speed about a third and in cost about a half.

A gasoline engine and small compressor capable of running one ordinary 2¼-in. machine will easily run two air-hammer stoping-drills and will break enough ordinary ground to supply a five-stamp mill. I am recommending this type of drill for consideration only as a stoping or raising drill, in other words, for upper holes.

It is often difficult to make comparisons between different machines in a mine, for time is too precious to waste on experimenting, but many conditions arise that compel a change of method. It is one thing to know a certain machine is doing more economical work than another, it is quite a different proposition to represent this difference by an equation, for all the various elements of the equation must be known, and these are not always obtainable. Moreover, actual tests under ideal conditions do not represent the average conditions. For example, the amount of powder used under different conditions, as, where the loading is done under the eyes of an experienced foreman, and where it is done by a crew of ignorant Swedes, gives divers results, both as to the cost of breaking per ton and the state in which the workings are left after shooting. While the foreman will use the necessary powder and only that necessary, the Swedes will fill the hole to the collar whether the hole be made with a ¾-in. steel or a 1¼-in. steel. The answer to this is that the foreman should deal out the powder according to the ground. The Swede answers this by filling up the first holes charged and leaving the lifters with insufficient powder to do the work and the next day the poor showing is imputed to "not enough powder." How does this bear on the subject? Thus: In ground where the walls are easily fractured and liable to cave, a small charge of powder may do the work as well as a big charge and also leave the walls intact. Now the drills I am discussing take ¾-in. grooved steel instead of the 1-in. steel that the 2¼-in. machines take. If we allow a quarter inch for clearance of the last steel used for a hole, the area of the bottom of the hole made with a 2¼-in. machine is over half again as large as that made with the ¾, and if we average a 4-ft. hole, taking into consideration that with the 2¼-in. drill there are at least twice the number of drills needed for a hole, the cubic contents of the holes will be about double. As a general proposition the nearer to the bottom of a hole the charge is, the better the result; but there are cases where the results might by detrimental, so in cases of irresponsible labor and loose walls these drills would take the place of the hand work often applied at a great disadvantage, because the results from shooting holes of larger diameter have been disastrous.

The following test is one extending over four weeks of actual work undertaken under average conditions, not as a test of machines, but one which demonstrated to my entire satisfaction the advisability of a change from the 2¼-in. machines then in use to the drill of the Waugh type, and which did actually discount the drills in use at the time. Another advantage was the fact that the work done by the compressor being limited, the number of places worked could be increased by using less power per machine. In a preliminary canter to test a new machine, with all conditions ideal, we drilled 13 ft. in 45 min. In actual practice about half this would be good work. Not only can the machine be set to work in any position with no appreciable waste of time, either on a timber set or a plank thrown across two stulls, but in the number of feet drilled per shift it did walk all around the reciprocating drill in that particular rock, which was a quartz porphyry of average hardness, in a raise 10 by 6 ft., over 100 ft. above the adit-level. The ground was very heavy, and required timbering within a set below the working face. With the 2¼-in. drill the average progress of the raise was 1⅛ ft. per day, while with the hammer-drill it was 1⅝ ft. per day. This would indicate slow drilling or poor breaking in both cases, but for the fact that the time taken for timbering could not (under the conditions) be used for drilling.

The relative cost for labor was as 6½ to 2½ in favor of the hammer-drill, while the powder consumption would average as 10 to 7 in favor of the hammer-drill. Thirteen 4-ft. holes was a round with the hammer-drill; this was generally made in less than six hours, sometimes in five, while the 2¼-in. drill could not make a round in an eight-hour shift. After shooting holes made with the hammer-drill the hanging wall was clean and slick, while the charges fired in the other holes broke into the hanging wall, requiring lagging where none was actually needed.

The cost of repairs for the hammer-drill in six months was $2, outside of gaskets that could have been made at the mine at a nominal cost, but which cost us about a dollar per month. As there are few wearing parts, it is hardly likely that any reciprocating drill with automatic screw-feed could compare with such a simple machine in the cost of keeping the machine to its work, but it is possible that in very hard rock this may be the case.

The air-pressure in the compressor room was kept at 110 lb., and probably at the working face, some 7000 ft. distant, it was about 85 lb. We found that a high pressure was more essential with the hammer-drill than with the reciprocating, probably because the cylinder, being larger, afforded a greater range of pressure where the blow delivered would be able to break the rock in the hole. The strength of the blow is determined more by the pressure than the amount of air; although this is not logical in one sense, for the greater the pressure the more the volume of air taken in at atmospheric pressure, it illustrates the point that there is no economy in a low pressure. We found also that our compressor, a Norwalk, did better work, and was subject to fewer variations at 110 lb. than at 90 pounds.

I have observed in various mines the air-pressure at 85 lb. in the engine-room. Now, with a possible loss of

about 5 lb. for every thousand feet of pipe, it seems to me that drills are working at a disadvantage, for, whether with steam or air, my experience has been that the machines should work under a pressure at least as high as 80 lb. (at the drill), and preferably at from 90 to 100 pounds.

Portland Cement.

THE country is being carefully searched for material suitable for the manufacture of portland cement. Deposits thoroughly satisfactory in chemical composition and at the same time so situated as to permit profitable marketing of the product, are exceedingly rare. The raw mixture which by its clinkering and grinding forms portland cement should contain about 75% of carbonate of lime. One of the most serious difficulties is that of finding limestones low enough in magnesia. The usual limit in well-established specifications is 5% of magnesium oxide in the finished cement, although the amount is sometimes limited to 3%. When the magnesia is present to the extent of 10 or 15%, the appearance of the stone, the way it effervesces with dilute hydrochloric acid and its hardness indicate its presence to that amount; but when it is as low as 5 or 6%, it is not possible to form by superficial examination any estimate of the amount of magnesia. It is of great advantage to be able to determine in a few minutes, and at a point remote from a laboratory, whether a material will probably produce good cement. A simple test may be made as follows: After powdering the sample in a mortar, transfer a measured portion to a test-tube. Add to this 1.75 c.c. of hydrochloric acid and when effervescence has nearly ceased, boil for a moment. Then add enough pure calcium carbonate to neutralize the excess of acid. Boil until steam issues freely from the mouth of the test-tube, then add water and mix thoroughly by shaking. Filter this and allow the filtrate to run into another test-tube containing 1.5 c.c. of sugar-solution (a cold saturated solution of granulated sugar) and 1 c.c. of potassium-hydrate-solution (30 gm. of pure potassium hydrate to 100 c.c. of water) which have been diluted with water and thoroughly mixed by shaking. If magnesia is present, a precipitate of magnesium hydrate will form at the line of contact of the two solutions. Its density is roughly indicative of the percentage of magnesia in the stone. The percentage can be estimated pretty accurately by running a parallel test on stone of known composition. If small pieces of the rock under investigation upon being treated with dilute hydrochloric acid in a test-tube disintegrate entirely, clay or shale will have to be added to the limestone; if the action of the acid ceases before all of the carbonate is dissolved and recommences when the clayey covering of the splinter is rubbed off, the stone is apt to need the addition of a purer limestone; but if all of the lime carbonate is dissolved yet the splinter retains its shape, the stone probably approaches closely the proper composition for portland cement.

RESPIRATORY APPARATUS IN FRENCH MINES.—Every mine in France employing 100 men underground at the same time must be provided with portable respiratory apparatus, ready for immediate use and allowing a miner to remain at least one hour in an irrespirable atmosphere. The number of these apparatus must be not less than two for each pit, placed in charge of an engineer or inspector familiar with their working, and provided with ten picked men, who will be trained in the use of these apparatus and sent to the seat of danger immediately whenever the necessity arises.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

The issue of patents for lode mining location was a recognition by the Land Department of the conformity of the proceedings to the local rules and customs of the district, and such ruling could not be challenged by third parties claiming rights which arose subsequent to the notices.

Lawson *v.* United States Co., 28 Superior Court Reporter 15, Oct., '07.

Priority of entry and patent alone does not conclusively establish seniority of location, so as to give the holder of a lode mining claim under such a patent the right to the entire width of the vein on its dip, where part of the apex of such vein is within such claim and part within an adjoining claim.

Lawson *v.* United States Co., 28 Superior Court Reporter 15, Oct., '07.

Where a mining lease provided for the payment to the lessor of a part of the net proceeds of minerals taken from the land, but contained no stipulation for a forfeiture through failure to open and work the mines, the law will construe the contract as if such a stipulation had been expressly written therein, and will adjudge such lease to be forfeited if within a reasonable time the lessee failed to carry out the purposes of the lease.

Starn *v.* Huffman, (W. Va.) 59 Southeast. 179, Oct., '07.

The owner of land conveyed the same by deed without reservation as to minerals. The grantee immediately deposited his deed for record. On the following day, in the presence of the first grantee, the original grantor executed and delivered to another person a deed for the minerals under such land, and in the presence of the first grantee, received the purchase price of such mineral. Under such circumstances, the original grantee was estopped to claim any interest in the minerals. While the purchaser of the minerals had constructive notice of the first deed, his conduct in paying the consideration for the minerals was sufficient to inform the first grantee that he had no actual notice of the original conveyance, or he would not have paid for the minerals knowing that the land had been conveyed to another. The conduct of the original grantee operated as a fraud upon the grantee of the minerals.

Virginia Co. *v.* Campbell, (Ky.) 105 Southwest. 129, Nov., '07.

The lessee of lands for drilling for oil and gas under an agreement to pay an annual rental for the time the wells produced gas in marketable quantity, was held liable for the rental only during the time such wells were so producing gas during the period for which such rental was claimed.

Roberts *v.* Fort Wayne Gas Co., (Ind.) 82 Northeast. 558, Nov., '07.

Under a lease of a certain vein or seam of coal for a term of years, the lessee to leave the mines in good condition for future working; and conditioned also that the lessee should remove from the vein leased 100,000 tons of coal of a size which would pass over a screen of §-in. aperture in each and every year of said term, it was decided that the lessee could not remove, after mining, such broken coal as would pass over the §-in. screen.

Hollenback Coal Co. *v.* Lehigh Coal Co., (Pa.) 67 Atlantic 897, Oct., '07.

Where a quantity of coal warranted to be of a certain grade was sold, but by mistake coal of an inferior grade was delivered, this did not relieve the seller from liability for damages and the measure of damages was the difference in the prices of the different grades of coal.

Missouri & Illinois Coal Co. *v.* Consolidated Coal Co. of St. Louis, (Mo.) 105 Southwest. 682, Dec., '07.

United Verde Mine.

By L. C. Graton.

*The production of blister copper in the Jerome district of Yavapai county, Arizona, in 1906 was about 38,500,000 lb., a notable increase over 1905. This came wholly from the United Verde mine.

The United Verde orebody occupies a zone of shearing so intense that the containing rock, a rather basic porphyry, has here been converted into a schist. Pyrite, chalcopyrite, and some zinc-blende, with varying amounts of quartz, have in places partially or completely replaced the schist, and in other places the schist is injected by veinlets and stringers of sulphides and others of quartz. As a rule the more massive sulphide ore contains more iron and zinc, while that consisting of alternating bands of sulphide and schist—the so-called 'slaty' ore—carries a much higher proportion of chalcopyrite. The ores are undoubtedly of pre-Cambrian age, like the inclosing rocks, and closely resemble certain pre-Cambrian copper ores from the Rocky Mountain region of northern New Mexico. Almost the entire output in 1906 came from sulphide ores, but a little oxidized ore, rather high in gold, added to the production. The ores mined are all of smelting grade and carry a high percentage of copper, the average yield in 1906 having been considerably above that of Bisbee and much higher than that of the other large pyritic deposits of Bingham, Shasta, and Ducktown. The content of the ores in gold and silver is decidedly higher than in any other of the large Arizona copper camps and far above the precious-metal yield of the pyrrhotite ores of Ducktown, although not very different from that of the Bingham and Shasta ores.

So far as present developments have shown, the orebody is an irregular rudely lenticular mass of large dimensions. The surface outcrop of the lens was about 800 ft. long. The shoot pitches northward and undoubtedly extends along the pitch beyond the region explored to date. There is some reason to believe that a fault, which brings the schist up even with the Paleozoic sediments close by, passes just west of the orebody, and it may be that the deposit now known is but the eastern section of a body whose remaining portion lies at an indefinite depth below the sediments.

Extraction is effected through shafts, although there is a tunnel reaching the 500-ft. level, and a new tunnel is being driven in 1907 to strike the lowest level of the new 1000-ft. shaft. Motor haulage is used on the principal levels. Square setting is employed only where absolutely necessary, and the use of timber is avoided as much as possible, owing to danger from fires. Native round timber is the kind most used. The system now prevailing is overhead stoping with horizontal back, and filling kept up within working distance. Work is carried on in certain portions of the 'fire country' by the employment of the plenum air-pressure system originated at Iron Mountain, Cal. The developed workings are not very wet, but considerable surface water finds its way into the mine through the caved ground, and, passing through the burning stopes, takes up copper and sulphuric acid. An extensive system of flumes allows the precipitation of most of this copper. The district is served by a narrow-gauge line owned by the company, which connects with the Santa Fe, Prescott & Phœnix. Oil is the principal fuel. European labor is extensively employed, but the wages are high, the pay for work in the fire country being $4 per day.

All the higher sulphur ores are roasted before smelting, the claim being made that the ores carry too high alumina to make pyrite smelting successful. The highest-grade ores are lower in sulphur and are smelted direct. It is an interesting fact that ore extracted from stopes which had been on fire for several years is oxidized only slightly, and not at all except along fractures. Limestone flux is quarried along the railroad near the mine. Silicious material is encountered in the workings in sufficient quantity to supply converter lining. The coke, which averages 10% of the charge, is from Colorado. The settling of ground under and around the smelter appears to have ceased, and a new 20-ft. furnace is being added in 1907. The ground considered as ore reserves in 1902 was lost to immediate availability by the fire and attendant caving. These stopes are now gradually being reclaimed, but most of the ore now being mined comes from stopes that were unknown three years ago.

Map of Arizona.

LOW-GRADE CHROMITE ORES may be concentrated into a commercial product. This is done at the Black Lake No. 1 mine in the province of Quebec, Canada. All ore carrying between 10 and 40% chromite is put through a jaw-crusher and a stamp-mill. After it passes through a 22-mesh screen it goes to Wilfley tables; the resulting concentrate carries 50 to 51% chromite. The best of the tailing from the tables is run to another table, and the resulting concentrate has 10 to 13% chromite.

*Abstracted from 'The Production of Copper in 1906.' Advance chapter from 'Mineral Resources,' U. S. Geological Survey.

The Fault Problem.

By T. C. CHAMBERLIN.

*The general conception of the relations of thrust to tension in the outer part of the earth's shell, which constitutes the soul of the views herein submitted for trial, is not without important bearings on ore deposition. Far from making the two systems of faulting mutually exclusive, and the presence of the one an argument for the absence of the other, the one is made to presume the other, in the following sense: The great bulgings of the outer part of the earth, which are assigned to compressive deformation and are accompanied by compressive faulting, are made the conditions precedent to the creep-faulting, since these are made dependent on the gravity-differentiations to which the bulging gives rise. The creep-faulting obviously follows the thrust-faulting in time when the two are thus genetically related, with an interval between. This sequence is believed to be economically important. Compressive stresses may be competent to rive the shell extensively and deeply, but they do not furnish conditions favorable to the gaping of the fissures, in general, but quite the reverse. While the compressive stress is on, the permeation of water, of whatever source, and in whatever direction tending, is antagonized, in the main. Given a pressure equal to 5 or 6 miles of rock-load, and penetration is practically prohibited. Much inferior stresses are competent to force the blocks of the shell into close contact and restrain circulation. Compressive stresses, taken in general, and neglecting attendant special cases, may be serviceable to vein deposition in the preliminary act of fracturing the rock, but to this their immediate serviceability seems to be largely limited.

The succeeding relaxation assigned to creep is, however, precisely the ideal agency required to complete the conditions for free circulation and for the reception of vein deposits and all related deposits. This is not solely limited to those cases in which the ore is deposited in the gaping fissures thus prepared for it, but also includes replacement, impregnation, and other deposits which are dependent on the free admission and exit of waters through the avenues opened by the relaxative movement. So also, in so far as the deposits are dependent on the leaching of the rocks by waters, either superficial or deep, they are probably also largely dependent on the opening of the fractures by the relaxation of the pressure and the setting in of creep. The very slowness of the assigned progress of creep is favorable for the development of vein-filling, for it provides a slowly increasing receptacle for the slow process of deposition. The alternations of tension with minor episodes of compression, incident to the creep process, as previously pointed out, afford a ready explanation of many of the complexities of vein structure, especially those which show successions of growth, with intervening crushing, on the one side, and infalls, on the other.

The length of the interval between the compressive stage and some known phase of the relaxative stage may be such as to be very suggestive, if not decisive, as to the conditions that controlled the ore deposition. The interval may have been so great and the physiographic changes so notable, as to leave little or no question that the circulation was that controlled by the relaxative conditions in distinction from those of the compressional stage, and it may thus throw the mode of deposition necessarily into the class or classes compatible with the relaxative stages only. This is not a mere academic deduction. It is a conviction forced upon my attention from studies in some of the mining regions of the West. While these studies were of a limited sort, I do not think I am in error in urging attention to the distinction between the conditions of the compressional and relaxative stages in regions of great relief, and to the time interval between these.

The distinction between compressional and tensional conditions is probably also important in studying those ore deposits that are associated with igneous action. If I am correct in assigning volcanic action to the solution-fusion effected by the rising temperature of the middle zone, and in supposing that the fluid material is forced to the surface about as fast as formed by the differential stresses of the tides and other agencies, effusions of lava should be liable to take place at almost any stage of the earth's history, compressional or relaxative, and this is the general import of the geologic record. If the lava encounters the crust in a compressional condition, its egress is not only hampered but it is forced to occupy every available cavity and weak spot not only by its own hydrostatic pressure and elastic contents, but by the ascensional stresses which actuate it, and little or no adjacent space or porous rock is likely to be offered for ore depositions, which are thus constrained to limited diffusions and impregnations of the environing formation and to segregations within the lava itself. Not only this, but the prevailing compressional condition tends to prevent the opening of fissures after the lava has so far solidified as to prevent its occupying the fissures itself, and hence the secondary conditions that normally follow an igneous invasion are delayed. Almost the only line of relief from these restraining conditions is found in the doming of the shell above the intrusion with incidental tensional openings.

On the other hand, lava seeking exit through the crust when in a tensional state and affected by open fissures, is less forced to strenuous insinuation, and is more liable to leave minute fractures and porous zones uninvaded. Through these, magmatic waters may go out and meteoric waters may come in and promote deposition. As soon as the exterior of the molten mass cools and its penetration of the adjacent formation is stopped, fissures may freely be opened by the progressive relaxation normal to the tensional state, and circulation outward and inward be facilitated, while at the same time appropriate receptacles for the ores are prepared by the mechanics of relaxation and by the solvent action which the free circulation permits.

Because of these and similar considerations, I believe that if we can reach the heart of the major phenomena of tensional and compressive faulting, we will be on the road to the elucidation of one of the great classes of ore deposition, while the mechanics of faulting will find their solution as a necessary incident.

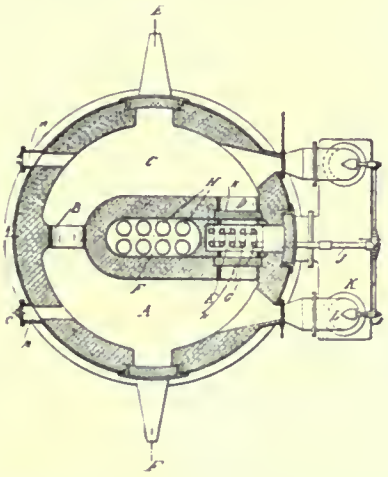
*From *Economic Geology*, October-November, 1907.

WHY MONEY IS SCARCE.—Many theories are advanced as to the principal causes of the scarcity of funds that has existed for a long time, says the *Wall Street Summary*. A banker in this city who has made a close study of the question, and who has been extremely conservative for many months, principally because of the monetary situation, says that he believes that a large amount of money is in the hands of laborers, artisans, and others whose wages have been very materially increased within recent years. He believes that people of this class are carrying about a much larger amount of money than ever before. Others who hold this same theory point to the fact that the newly-arrived foreign element is receiving much higher wages than was ever paid to that class of people until a few years ago, and that many of them hardly know what a savings bank is, and consequently are simply hoarding their savings.

MINING AND METALLURGICAL PATENTS.

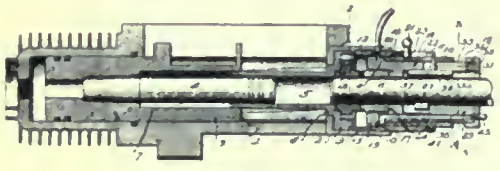
Specially Reported for the MINING AND SCIENTIFIC PRESS.

SMELTING-FURNACE WITH OIL FIRE.—No. 876,275; August Koch, Hanover-List, Germany.



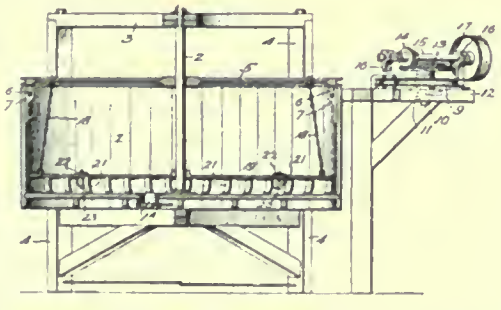
In a furnace of the character described, the combination of a plurality of chambers adapted to be alternately used for melting and preheating, oil vaporizing and air heating chambers located between said melting chambers, so that the heat radiated by the melting chambers will vaporize the oil and preheat the air in said air and oil chambers.

ROCK DRILL.—No. 875,869; Rolland S. Trott, Denver, Colorado.



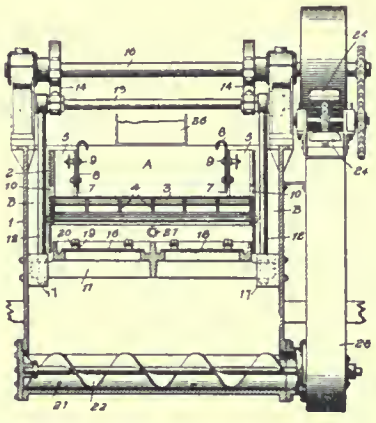
In a rock drill for changing drill-bits without stopping the engine, a cylinder, a reciprocating, non-rotative piston mounted therein, a pawl and ratchet and rifle toothed drill-bit rotating mechanism connected to said piston, a drill-bit in the reciprocative path of said piston, a drill-bit holding chuck arranged to hold said drill-bit and means including a clutch device for throwing said drill holding chuck into or out of engagement with said drill-bit rotating mechanism when said piston and drill-bit rotating mechanism is in operation.

APPARATUS FOR AUTOMATICALLY DISCHARGING ORE-PULP SANDS AND OTHER MATERIAL FROM TANKS.—No. 875,876; Jeremiah C. Winchell and Howard H. Winchell, Monte Vista, Colorado.



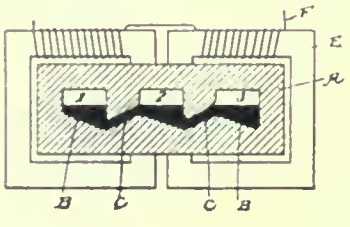
An automatic ore-sand discharger for cyanide tanks, comprising a tank, a shaft in the centre of said tank, a closable discharge aperture in the bottom of said tank, a scraper pivotally and slidably mounted on said shaft within said tank, a rotating sheave rotatably mounted on said shaft, and connected to said scraper by a flexible scraper rotating connection, and means for rotating said sheave.

APPARATUS FOR WASHING COAL, ORE, ETC.—No. 876,268; Alfred J. Diescher, Pittsburg, Pennsylvania.



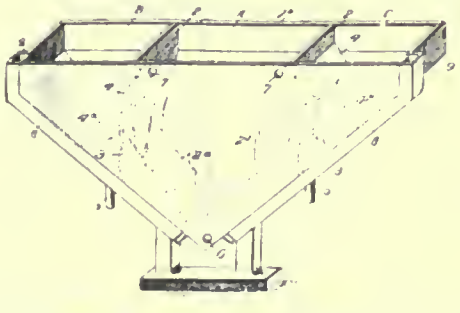
In a machine for washing coal, ore, etc., the combination of a tank having a main and one or more secondary compartments, the main compartment having an outlet for the discharge of light material, a screen arranged transversely of the main compartment below the level of the outlet therefrom, the main and secondary compartments being connected by open ports located above the screen and permitting a free flow of water from the main to the secondary compartments and means for maintaining a flow of water up through the screen and through ports leading to the secondary compartment or compartments, substantially as set forth.

CONSTRUCTION OF INDUCTION ELECTRIC FURNACES.—No. 875,801; Gustave Gin, Paris, France.



In a furnace of the type set forth, a hearth provided with a plurality of receptacles for molten metal, each having a longitudinally inclined bottom, laterally closed conduits connecting said receptacles and electro-magnetic means adapted to set up an induced electric current in metal contained in said receptacles and conduits, substantially as and for the purpose specified.

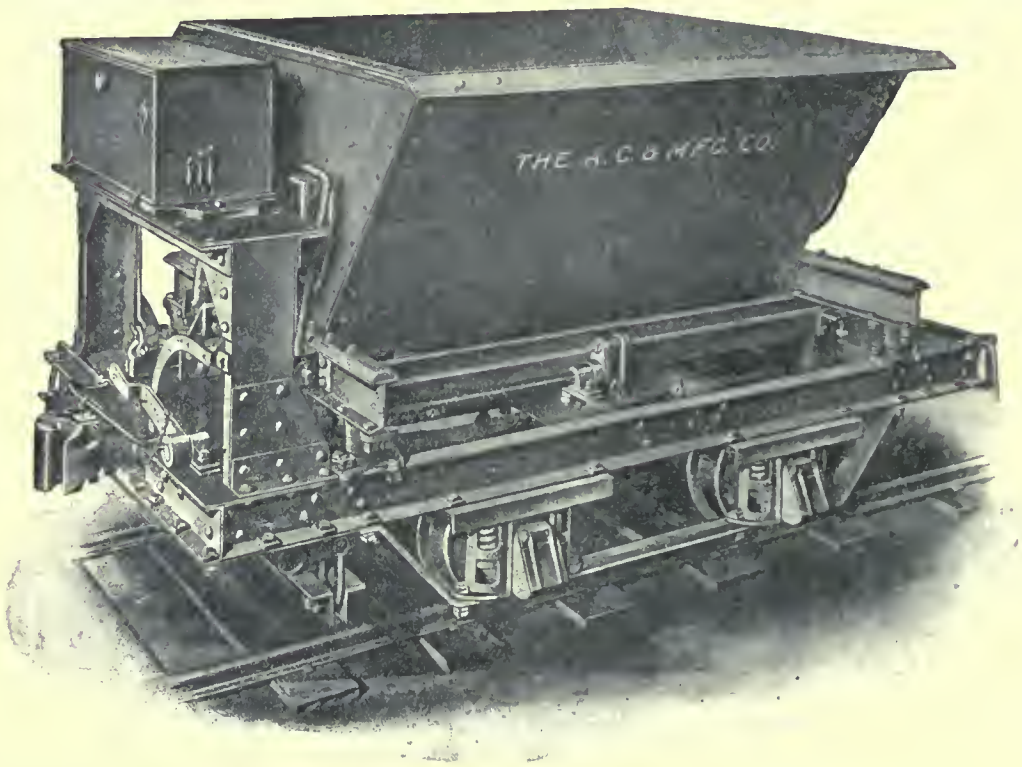
WATER-ECONOMIZER FOR JIGS.—No. 875,850; Thomas Rowe, Dollar Bay, Michigan.



In an apparatus of the character described, a receptacle for the reception of tailing, said receptacle having sloping side walls and formed in its front wall at the bottom thereof with a discharge outlet and also formed near the upper edge of its front wall with outlet orifices, and overflow launders connected to the sides of said receptacle and extending down underneath said sides and discharging at the lower ends thereof.

Scale Charging-Car.

Through the courtesy of the Atlas Car & Mfg. Co., of Cleveland, Ohio, we are able to present to our readers a new type of scale charging-car, such as is used around smelting works and furnaces. The car is moved either by hand, or by small locomotives. This type of car can be built from 30 to 150 cu. ft. capacity. It is intended to empty on either side of the track. The body being practically balanced and held in position by two bales, one on either end of the body, the car is adapted so that one man can manipulate it. The centre of gravity sets low, which insures easy riding. The hopper is made of steel plates, re-enforced around the edge and on the ends, on malleable iron rockers. The rocker ways are tapered so that no material can lodge where it would impede the hopper. A sub-frame is provided; it is made of structural material and well braced. The end thrust is taken up in the centre as well as at the ends. Cross-frame supports are provided, also a check chain, to hold hoppers from going too far. The main frame is provided with four cone-shaped steel castings, which fit into corresponding male castings secured to the sub-frame. When the car is in motion it is intended that the sub-frame is setting on cone supports. This holds the mechanism in true alignment when the scales are out of action.



Scale Charging-Car.

The relieving device is a new feature, taking the entire scale mechanism off the pivots and knife-edge when the car is in motion. When material is to be weighed the movement of the lever, shown on the platform, brings the scale into action, through the medium of a link connected to the main lever. This takes off the wear and friction of the knife points, also the strain, adding to the life of the scales and accuracy in weighing. The scale-box is known as the Miller type, having the beams parallel with each other instead of vertical as in the Realy and other types. On the ends of the box are three triggers. These are used when material is to be weighed. The beams are brought into action by lowering the trigger to be used, each trigger representing a beam. The tare beam is not indicated. As many as seven different materials for charging may be weighed on these cars, depending upon the number of beams. An indicator is provided on the outside of the box, showing the action of the beams, in order that the operator can apply the right amount of material to the hopper. Each box is provided with a Yale lock to prevent tampering. Proper means of adjustment is provided for all wearing parts. The main car-frame is composed of heavy I-beams which are well trussed and braced with intermediate channels and plates so as to keep them in alignment. End thrust on body and scale mechanism is well taken care of, as the shunting of such cars is excessive. The wheels and axles are made heavier than usual, also boxes are made of malleable iron, pedestals of malleable iron, with duplex springs, bronze bearings, and ample space for oil waste. The duplex springs prevent the jar on the scale mechanism and add to the life of the car in general. Owing to the fact that the smallest curves are necessary to the economical handling of such cars around smelters and furnaces, an automatic radial draw-bar is designed so that these cars can radiate in trains without side friction or binding. Cars can be coupled on a curve or in any position, also uncoupled through the uncoupling lever, by standing on the outside of the cars, thereby facilitating the handling of them. The Atlas Car & Mfg. Co. designs cars of all classes for smelters and mines, this being one of the latest. The shops are especially adapted for producing duplicate work of this sort to the best advantage.

Catalogues Received.

THE WOOD DRILL WORKS, of Paterson, N. J., is distributing a circular containing testimonials as to the merits of the Wood drill.

THE MURRAY IRON WORKS CO., of Burlington, Iowa, has issued its Series D, No. 7 catalogue entitled 'Nomenclature of Murray Corliss Engines.'

THE L. C. TRENT CONTINUOUS FILTER CO., of Reno, Nev., has sent us its 'Bulletin No. 1,' which describes its continuous filtering and straining machines.

THE WEBBER GAS ENGINE CO., of Kansas City, Mo., has issued 'Brochure No. 55,' containing a statement of the advantages of using gas power instead of steam power.

THE ELECTRIC CONTROLLER & SUPPLY CO., of Cleveland, Ohio, has issued a finely illustrated catalogue entitled 'Lifting Magnets.' The Type S magnet is extensively used for loading charging boxes for open-hearth furnaces, and for a great variety of other purposes involving the transferrence of pieces of iron or steel; the Type F magnet handles ingots and billets, and the Type R magnet large irregular pieces of iron.

Editorial.

OUR DISCUSSION DEPARTMENT has been honored by the information concerning green gold given by Mr. Thomas K. Rose, chemist to the Royal Mint, and Mr. Frank A. Leach, director of the United States Mint. In this issue Mr. Leach records the latest experiments devised to ascertain the cause of the color of green gold.

IN OUR ISSUE of January 18 we published a thoughtful article by Mr. Frank A. Ross, criticizing the Lemieux Act, which was intended to deal with industrial disputes in Canada. Since the article appeared, the commission, appointed under the Act, has held a long session at the St. Eugene mine, of the Consolidated Mining & Smelting Company, at Moyie, and the result was that the men refused to accept the scale recommended by the commission, so that mining operations have definitely ceased. This confirms the judgment expressed by Mr. Ross.

WE NOTE with pleasure that excellent selections have been made for officers of the Institute this year. There have been times when the nominations have been anything but representative, but the circular just to hand indicates unusual success in the choice of members to serve on the council. Mr. Hammond remains president. For new vice-presidents we shall have J. Parke Channing, John B. Farish, and F. W. Denton; no worthier representatives of American mining engineering could be found. For new councilors, we shall have W. H. Shockley, C. R. Corning, and R. V. Norris; here also we find men of the highest reputation and admirable exemplars of correct practice. The election takes place on February 18, but it is a formality only. Fortunately, the members of the Institute have been well served by the nominating committee—a mysterious entity, but evidently highly intelligent.

PERSISTENT RUMORS have been current on Wall Street to the effect that the Guggenheim family had lost control of the American Smelting & Refining Company, and that the Standard Oil coterie was now dominant in the affairs of this important corporation. Thereupon Mr. Daniel Guggenheim came out with a positive denial of any such change, asserting that he and his friends had been loaning money, not borrowing it. Unfortunately it is considered proper nowadays in business to make statements that may be technically correct although inferentially wrong, so that a *dimenti* is often unconvincing. We have reason to believe that the Guggenheims have had to borrow heavily during the past year and in doing so they have been compelled to hypothecate some of their shareholdings.

but that they have managed to retain command despite some degree of financial embarrassment. And we can say with the utmost sincerity that we would be the last to welcome the further ascendancy in mining of the Standard Oil people; the heavy hand of that unscrupulous organization is already laid upon too much of American industry. In this connection we refer our readers to an abstract of the Government report on the petroleum industry, appearing on another page of this issue.

MOST OF US have heard of theoretical extractions that failed of fulfilment. We have heard of mills that made a 60 per cent extraction on top of a 90 per cent estimate, and the difference has been credited to absorption by the copper plates in a stamp-mill or the wooden staves of the cyanide vats; and such transfers of responsibility have held good until that day of judgment coming to all erroneous engineering calculations. But we can now record an advance upon earlier practice in this regard. The management of a large mill in Sonora made a shipment of precipitate to the refinery at Omaha. In order to value the shipment, the figure giving the average daily tailing was subtracted from that representing the average mill heading. Upon receipt of the smelter returns, it was found that the precipitate was much less valuable than expected, so what did they do but bring a claim against Wells, Fargo & Co. (who transported the shipment) for the entire theoretical discrepancy, and then the amount of the claim was entered on the books as an asset!

State Mining Bureau.

ON THE LAST DAY OF 1907 Mr. Charles G. Yale was dismissed from the post of statistician to the State Mining Bureau. This fact was known to us at the time, but no mention of it was made pending a protest presented to the Governor by several representative men. The official chief of the Bureau is the Mineralogist, who, at this time, is Mr. Lewis E. Aubury. The Governor of the State and the Trustees of the Bureau alike protested against the summary dismissal of a man so long honorably identified with the Bureau—a man whose name carries more of authority in mining affairs than that of half a dozen State Mineralogists—but as Mr. Aubury owes neither his nomination nor his tenure of office to either the Governor or the Trustees, he declined to reconsider his action. It was fitting that the episode should be completed by the selection, as a successor to Mr. Yale, of Mr. David H. Walker, a reporter on the *Call*, a daily paper to which Mr. Aubury is indebted for many flattering notices. We forbear from further attack upon the present State Mineralogist, for he is only a link in a disgraceful system, but we deem it our duty to lay certain facts before our readers, in the best interests of the mining industry of California.

The office of the State Mineralogist of the State of California has been in the gift of the Southern Pacific Company for twenty years. W. H. Irelan was the nominee of George Hearst, senator and railroad henchman; J. J. Crawford was given the appointment by John Wright, political manager at Sacramento for the railroad company, because Mr. Crawford handled the El Dorado county delegation for Wright; A. S. Cooper was put into office by the manager of the Pacific Improvement Company, a subsidiary of the railroad company. One man was made Mineralogist in order that he might examine the coal deposits in the interest of the Southern Pacific, but at the expense of the State; another man was given the appointment in the expectation that he would investigate the oil-fields for the Southern Pacific. Then came Lewis E. Aubury, whose term of office has been signalised mainly by a fight over timber lands in Plumas county, nominally in the interest of the State, actually in behalf of the Southern Pacific; nominally against H. H. Yard and others, actually against the Western Pacific. The public has been bamboozled into believing that this fuss about fraudulent land entries was prompted by the call of duty; it is all flimflam. So far as we know the evidence indicates that the procedure of H. H. Yard and his associates is such as any citizen might legally follow regardless of railroad affiliations. Whether the claims located cover real placer ground or valuable timber land it is for the Federal officials to say, for it is government land absolutely. From an economic point of view, the State of California profits equally whether the land is made to produce lumber or gold. Not only is it no part of the duty of the State Mineralogist to investigate land frauds, but the Federal authorities, who are responsible, have made an enquiry and it is known that the Commissioner of the Land Office has not seen fit to invalidate the entries attacked by Aubury. It is hardly necessary to add that we have no motive in making these statements save the desire to serve the community; Messrs. Yard and Aubury, the Western Pacific and the Southern Pacific are to us only representatives of conflicting interests; the MINING AND SCIENTIFIC PRESS is not bound by a single political or financial thread to anyone.

To return to our story: By reason of Mr. Aubury's incompetence, an effort was made to prevent his re-appointment at the end of 1906, and soon after his belated re-appointment by Governor Pardee it was arranged that he should resign on or about March 1, 1907, with the understanding that Mr. Ross E. Browne should succeed him, as was stated in our issue of July 27. We need not tell our readers who Mr. Browne is, nor how eminently fit he is for the office designated. Mr. Browne had just returned from South Africa and was unwilling to undertake the work of re-organizing the Bureau, until it was urged upon him by Mr. Yale, by the Trustees, and by other friends. He finally agreed to take the post for at least one year, long enough to put its affairs on a better basis. In the meanwhile Mr. Aubury was to resign gracefully, to accept a lucrative appointment in the Land Department of the Southern Pacific. Mr. Browne was offered the place of State Mineralogist by Mr. W. F. Herrin, the political agent of the Southern Pa-

cific. It is now proper to inform our readers that the Governor of California is a Mr. James N. Gillett, but he did not appoint Mr. Browne nor arrange for Mr. Aubury's resignation. Why should he? Mr. Herrin made him Governor, so why make even a pretence of possessing the appointive power. Mr. Herrin arranged everything. But Mr. Aubury did not resign after all; he submitted that he was engaged in important work, to wit, the prevention of timber-grabbing in the northern part of the State, that is to say, the hindering of the construction of a rival transcontinental railroad. His reasons for retaining office satisfied Mr. Herrin; what the Governor thought, does not matter.

Now we return to the dismissal of Mr. Yale. Charles G. Yale is known wherever the mining industry of California is known, for 23 years he was editor of the MINING AND SCIENTIFIC PRESS, he was one of the founders of the California Miners Association, for many years he has been in the employ of the United States Mint and of the Geological Survey—in fact, for the time of a whole generation he has been foremost in all that concerns the systematic recording of mineral production and mining advancement. He has been statistician to the Bureau for 15 years. Out of 49 bulletins issued by the Bureau he himself wrote not less than 25; out of the 8 issued since the earthquake-fire he has written 7; he edited and prepared for the printer (including index) all of the 49 bulletins, save 3. Mr. Aubury has been the State Mineralogist for 6 years and during this period he has not written one bulletin or report, although his name is attached to the copper bulletin, of which he did not write a single line. On the whole, the work of the Bureau during recent years has been unworthy of its high-sounding name; tons of field reports have been consigned to the paper mill, because the material is unfit for publication. What the Bureau has done, outside of Mr. Yale's reports, is scarcely worth mentioning. The last important contribution to technical literature was the bulletin on dredging, the best of which was the work of John D. McGillivray, although the authorship is credited to a genial politician and promoter who is now across the divide. The present State Mineralogist had no special training for the work, he is a regrettable accident. It might be supposed that the Trustees of the Mining Bureau would have adjusted affairs; the personnel of the board was indeed of such a character as to warrant the highest expectations; namely: Curtis H. Lindley, F. W. Bradley, E. A. Stent, Louis Janin, and Harold T. Power. It would be difficult to select men better fitted to represent the mining industry of California. The first three of these gentlemen resigned two months ago and they have been succeeded by Frank Griffin, A. H. Ward, and T. C. Deane. But the Trustees act merely as an auditing committee, with no authority to direct the work of the Bureau nor to advise concerning the expenditures; they are trustees only in name. For instance, all of the members of the old board joined in recommending the selection of Mr. Browne, just as the new board protested against the dismissal of Mr. Yale, but to no effect. Nevertheless, the present Trustees can be held responsible for the appointment of Mr. Walker in place of Mr. Yale, if it becomes a fact, for the law of California says that all appointments of the Mineralogist shall be made "subject to the approval and confirmation of said board of trustees, and shall not become effective unless so confirmed and approved."

This is the truth in all its naked ugliness. Shall we blame Aubury? Yes; but that will do no good. He is ephemeral; the conditions that put him where he is, will persist. Shall we attack W. F. Herrin? That also is useless, for were he to resign tomorrow, his work would be perpetuated by another of the same kind. Shall we anathemize the Southern Pacific? Even that is wasted breath, for the railroad company's malign activity in politics is the result of conditions; it did not create them. If the people elect a legislature that can be bought like a sack of potatoes, and if the railroad company is in danger of proscription unless it bribes the legislators, can you blame the railroad company for defending itself first and then trespassing on the rights of others? We do blame the railroad company and its officials for corrupt practices and subversion of law, but we charge a large part of the disgrace of such procedures to the people, to the voters—and especially the non-voters. We blame you, Sir, who think politics a dirty business and neglect your civic duty; you, Mr. Professor, who cannot spare the time to vote because you want to be on the golf tee early on election day; you, Mr. Merchant, who consider legislators—even the best that money can buy—as outside your ken. The stream cannot rise higher than its source and if the people will not attend to their civic duties, then incivism becomes rampant, and you get your Auburys, Herrins, and Gilletts.

You say this is not practical and that it devolves upon criticism to be constructive. We admit it. At the present time the people of the State are getting nothing from the Bureau save its museum and library. The Bureau could be an immensely useful institution, but it never will be while it remains an appanage of the Southern Pacific Company. Unless it can be divorced from politics and put into the hands of competent men, it would indeed be better to reduce the Bureau to the status of a library and museum. The public imagines that it is represented by the Trustees; they are but a blind to the corrupt play of politics. That is why Messrs. Lindley, Bradley, and Stent resigned. They found that their recommendations were disregarded, that they were asked to audit expenditures over which they had no control and into which they could make no effective enquiry. Until the administration of the Bureau is put on an intelligent foundation, no honorable man should accept office either as Mineralogist or Trustee. We hope Mr. Browne will not dishonor himself by accepting office from the political agent of the Southern Pacific and we ask that the present trustees, especially Mr. Janin and Mr. Power, both men highly respected in this community, resign from an office that is a sham.

The remedy is fairly obvious: The Mineralogist should be chosen by the Trustees and he ought to be

answerable to them; the Trustees ought to have terms of varying length and vacancies should be filled by the survivors, after the manner of the Public Utilities Commission of New York State. The first board of Trustees should be selected by the Governor, acting under the advice of a committee representing the organized business and professional interests of the State, such as the Chamber of Commerce, the Merchants Exchange, the Miners Association, and so forth. If the character of the first board came up to that of the Trustees actually selected three years ago, there would be some guarantee of the fitness of their successors, under the plan adopted in New York. Then, but not until then, would the position of State Mineralogist be filled by a man of the Ross E. Browne or Charles G. Yale type. As now administered, the Mining Bureau is a mere exhibit of the corrupt influence of railroad politics and a disgrace to the State of California.

The President's Message.

AFTER we had gone to press last week, we read the message transmitted to the Congress of the United States by the President; if it had been published earlier, some comment would have appeared in these columns: for we are among those that consider his messages important. It is a sufficient commentary on the poor journalistic enterprise and the un-American slowness of even our least bad San Francisco papers that they should not give any editorial comment on so important an event until nearly 48 hours after the message was received and that even then their remarks were trivial to a degree. *The Chronicle*, the owner of which is one of the most vivid examples of the predatory rich so seathingly rebuked by the President, says: "In a little over a year the President will be free to devote his entire time to the lecture platform." But even this ultimatum required 36 hours of cogitation. It is not necessary for us to define the nature of the grand work done, in so unconventional a manner, by the President, for on the very day his message was read at Washington, it was said by Mr. Charles E. Hughes, the Governor of New York—a man no less his rival in politics than he is his rival in the work of constructive statesmanship—that the administration of Mr. Roosevelt "has impressed the popular imagination and won the confidence of the people. The country is under lasting obligation to President Roosevelt for vigorous opposition to abuses and for the strong impulse he has given to movements for their correction. Differences of opinion now, as always, exist with regard to the best means of solving some of the extremely difficult problems that are presented. But those who earnestly desire progress and the establishment of our security on its necessary foundations of fair dealing and recognition of equal rights appreciate the great service he has rendered and the fundamental importance of the purposes he has had in view. We shall have in the next campaign a notable vantage ground, gained through the general admiration of his strong personality and the popular appreciation of the intensity of his desire to promote the righteous conduct of affairs and the welfare of his fellow men." This is a tribute as true as it is generous. There can be no question that to Mr. Roosevelt it has been given to be the spokesman for the American people to a degree unknown in American history, for even Lincoln was the representative of only one party, while Mr. Roosevelt has won the support of the people generally and even the commendation of the acknowledged leader of the Democrats. We confess to an enthusiastic belief in the usefulness of the work he has done, and is doing; and while aware of many blunders committed by him, by reason of a curious blending of personal impulses and machine politics, we hold that these very mistakes have confirmed the belief in his sincerity, for the blunders have been small while the splendid purpose of his policy has been made repeatedly manifest. To those not entangled by politics and finance, it is amusing to watch how the predatory financier and the politician of the corrupted and corrupting kind are joining hands in their bitter hatred against Mr. Roosevelt, because he has dared to spoil their game. They have been used so long to the complacent type of President, like McKinley, that they protest in the manner of Russian grand-dukes or the Hohenzollern themselves when their privileges are endangered. Here in San Francisco we have heard what are called in the drivel of the daily paper 'magnates,' that is, presidents of street car companies and successful promoters, talk of the effort to rid our City of its municipal corruption, as if the law officers were a mob and they, the 'magnates,' hereditary autocrats. The thing is pathetic, for these men that arrogate the attitude of a privileged class were plain workmen, or not so good, only twenty or thirty years ago. In a real democracy neither wealth nor privilege should determine a man's status, but his conduct. In Europe high birth will throw a halo around a low act; in America great wealth will give glamor to grand larceny; both ways of thinking are stultifying, both are destructive of any real ethical standard. Worth makes the man: to those that are of good birth as to those that are possessed of great wealth, there is simply an added obligation, as there is usually a better code of conduct. The *noblesse oblige* of Europe should be translated into the *obligation of riches* in America.

It is a curious fact that Mr. Roosevelt is esteemed highest by the plain people of his own country and by observant foreigners across the Atlantic. In both cases his hold on their imagination is due to the fact that he has succeeded to an astonishing degree in expressing the trend of general opinion, not as a groveling politician with his ear to the ground but as a great tribune thoroughly in touch with the tendencies of his day and generation. Even if regarded in the least sympathetic way, he is a safety valve for the pent-up protest of an industrial community heartily sick of the industrialization of all that makes life worth living, of a people that is beginning to ask, in the eloquent words of the president of the University of Virginia: "Can we industrialize our lives without commercializing our souls?"

Personal.

R. GILMAN BROWN is in Chile.

RICHARD PEARCE is in London.

WALTER H. WEED is expected at Guanajuato.

MARK L. REQUA has returned from New York.

C. W. MORSE has returned to Berkeley from New York.

JOHN E. HARDMAN has changed his office to 112 St. James St., Montreal.

E. C. D. MARRIAGE, recently of Pioche, Nevada, is on a visit to London.

D. CURRIE, of Lake & Currie, sailed from London for Australia on January 30.

T. M. LOWAY, of Camborne, Cornwall, has sailed for the Gold Coast, West Africa.

N. M. ZOPH has gone, with Douglas Waterman, to the Ponderosa mines in Chile.

UTLEY WEDGE, of Philadelphia, has been visiting the smelters near San Francisco.

C. M. FUELLER has returned to Denver from the examination of mines in Nevada and California.

H. W. TURNER has moved from Portland to San Francisco; his office is at 502 California Street.

LEWIS T. WRIGHT sails from New York on February 8 by the *Lusitania* on a short visit to London.

ROBERT H. RICHARDS and FRANK E. SHEPARD are visiting the Washoe smelter, at Anaconda, Montana.

S. J. SPEAK, of the firm of Hooper & Speak, London, has left for Siberia on a professional engagement.

WILLIAM M. BREWER is examining prospects on the Queen Charlotte Islands, off the coast of British Columbia.

WILLIAM M. FITZHUGH has been investigating the dredging operations on the Yuba; he goes to Colombia shortly.

M. B. RAPP is superintendent for the Franklin Mining Co., operating a lease on the Gold Sovereign mine, Cripple Creek.

GERALD M. BROWNE, of the firm of Pearse, Kingston & Browne, London, has left for Siberia to inspect the Kluchi gold mines.

J. M. CALLOW has just returned to Salt Lake City from Telluride, Colorado, where he was directing work at the Tomboy mill.

W. C. WYNKOOP, whose office is now in the Merchants Exchange Bdg., San Francisco, has gone to Colorado on professional work.

LOUIS C. MAYER and HOWARD W. HOLMES, mining and civil engineers, are now associated, with offices at 624 Santa Marina Bdg., San Francisco.

W. L. STEVENS, superintendent for the Tennessee Copper Co., has been with W. H. Weed, examining the La Dicha mines, in Guerrero, Mexico.

D'ARCY WEATHERBE crossed the Andes from Catamarca in the Argentine, to Chile, and then returned to Buenos Ayres. He will sail for London on February 18.

ENGLE CARPENTER and JOHN C. BRENNON, of the Benito Juarez Mines Co., City of Mexico, have been at Chicago closing contracts for machinery for the various properties they direct in Mexico.

RICHARD S. MCCAFFERY has resigned as manager for the Salt Lake Copper Co. and has accepted the position of superintendent and metallurgist for the Tintic Smelting Co., now building a smelter.

E. R. RYAN, formerly assistant general manager of the Guanajuato Development Co., has joined the firm of Carpenter & Brennon, mining engineers, of the City of Mexico, and the firm will be known as Carpenter, Brennon & Ryan.

The firm of STEINHART, VOGEL & CLOUD, consulting engineers and metallurgists, London, has been dissolved by mutual consent. T. C. Cloud continues to practise as a specialist in copper smelting. He is consulting metallurgist to Elliotts Metal Co. in South Wales. J. F. L. Vogel is taking up the management of a tungsten works in the north of England. O. J. Steinhart resumes practice as a consulting metallurgical engineer.

Only one of the rope shops of the JNO A. ROEBLING'S SONS CO. was destroyed in the recent fire at Trenton, N. J. All orders will be promptly filled from the large stocks on hand in their warehouses at Los Angeles, San Francisco, Portland, and Seattle.

Dividends.

On February 1, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 125 of $60,000. This makes the amount of dividends paid since January 1, $120,000, and the total to date $9,936,000.

General Mining News.

ALASKA.

Advices from Fairbanks indicate that the strike which was ordered by the local miners union for Feb. 1 has been a dismal failure; the few men that went out were quickly replaced. Many of the members of the union condemn the officers for calling the strike, saying they won their point when the operators agreed to the scale of $5 for an 8-hr. day, with board and lodging. Now the operators have established a card system which gives assurance of work, prompt payment of wages and sick benefits, but bars union men from obtaining employment in the mines. Although many men are arriving over the trail and finding employment, the operators issued a statement on Feb. 4 saying that they would give employment to 1500 men more than they had at that date. The outlook now is that the Tanana district, with its labor troubles settled, may produce $15,000,000 this season.

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—The operations of the Tombstone Consolidated Mines Co., at Tombstone, are centred at two main shafts, the main pump-shaft and the Emerald. The former is now 1000 ft. deep, and the pumps installed therein are raising to the surface 4,700,000 gal. of water every 24 hr. In addition to the present pumping force the company has ordered and will soon install at the 1000-ft. station two Prescott pumps, each of 1200-gal. capacity per min. A lift of 1000 ft. will be made with these pumps. This combined pumping force, it is anticipated, will keep the lower workings all over the district reasonably free from water. At the Emerald shaft, which is 900 ft. deep, a winze has been sunk from the 900-ft. level, which opened a body of ore running well in chalcocite, silver, and gold. This discovery at the depth mentioned is considered of importance to the district. Sinking in this winze continues with the purpose of reaching 1100 ft., which corresponds to the 800-ft. level in the main pump shaft. The bulk of the ore being mined and milled comes from the 600-ft. level and levels above it in the pump shaft. These ores are largely oxidized, quite silicious, carrying 0.13 oz. gold, 6.6 oz. silver per ton, and considerable lead. The sulphides come in below the 600-ft. level. The 40-stamp mill handles 200 tons of ore per day, the pulp from the batteries passing to tables from which there is a product of one ton of concentrate from 60 tons of ore. This product contains lead, silver, and gold and is worth $200 to $300 per ton. It is shipped to the El Paso smelter. The table tailing and middling pass to hydraulic sizers for separating the sand from the slime, Callow tanks being used as pulp thickeners. The sand and slime materials are cyanided separately. Shipments of about 15 carloads of crude ore per month are made from the Emerald mine, carrying silver, lead, and gold. A strike of rich silver-lead and gold ore in the old Lucky Cuss mine, belonging to the same company, was made some time ago at 170 ft. below the old water-level. This includes horn-silver and native silver. This company uses oil as fuel under the boilers, which the superintendent, E. W. Walker, states is more economical than coal for this property. W. F. Staunton, general manager for the company, spends a part of his time at the property of the Imperial Copper Co., at Silverbell, where a one-furnace copper smelter, with copper converters, is now ready to be set in operation.

Tombstone, Jan. 31.

(Special Correspondence).—Bisbee is rapidly recovering from the financial depression.——On Jan. 29, the Copper Queen and Calumet & Arizona companies each blew in one more furnace at Douglas; this makes seven out of nine furnaces of the first company and all five of the Calumet & Arizona furnaces that are now in operation. When the production was curtailed last December only six of the Copper Queen and three of the Calumet & Arizona furnaces were kept running. The monthly production of the camp is now about 12,000,000 lb. of copper, of which the Calumet & Arizona is making about 3,000,000 lb., the Superior & Pittsburg 2,000,000 lb., and the balance is made by the Copper Queen Co.——Underground development is going steadily ahead; it is safe to say that never in the history of the camp has so much ore been developed in any one mine in the same time. Probably the most important development during the last month was on the 1200-ft. level of the Hoatson mine of the Superior & Pittsburg Copper Co. Here a body of good-grade ore was exposed for 200 ft. in one direction; as it carries much iron oxide it is valuable as flux. The Hoatson shaft is down over 100 ft. below this level, and as soon as sufficient depth for a slump has been gained, the 1300-ft. level will be opened.——In the Oliver mine of the Calumet & Arizona company a large quantity of sulphide ore has been developed on the 1250-ft. level.——The Copper Queen company is going steadily ahead with its work at the Sacramento shaft; eventually all the ore from the mines will be hoisted through this shaft. Long drifts are being driven from the shaft to the various mines; electric haulage will be used.——At present the Shattuck & Arizona company is doing very little work. The Denn Mining Co. is boring a diamond-drill hole. B. M. Pattison has resigned as general manager of this and the Shattuck & Arizona company, and as yet no successor has been named, although it is rumored that S. A. Parnall will be appointed.——The trolley line from Warren to the mines has been completed.

Bisbee, Jan. 31.

F. C. Dezendorf and L. G. Gillett, agents of the United States Land Office, are looking into the character of the ground in the Bisbee district which has been taken up under mineral application, and concerning which there is some question.

GILA COUNTY.

The Superior & Boston company has made its first shipment to the Old Dominion smelter, the consignment consisting of two carloads of 8% copper ore from the Limestone shaft.——From the Gray mine of the United Globe company about 100 tons of ore are shipped daily to the smelter by way of the Arizona Commercial railroad, instead of the former horse transportation system.——The Independence mine is furnishing the Old Dominion smelter 15 to 20 tons of sulphide ore daily; the smelting company will furnish additional teams to double the shipments.——Good lump sulphide ore is being shipped from the Continental mine; 25 men are employed.——Ore from the Gibson mine is arriving at the Old Dominion smelter at the rate of about 25 tons daily.——At the Black Hawk mine in sinking a winze the ore has increased in copper content from 7% at first to 14% at a depth of 45 ft.; the ore contains malachite and a small quantity of chalcocite.——The raise from the Black Oxide adit is 100 ft. long, and driving horizontally on the vein will soon be commenced.——The Buffalo Hill mine is being explored on the 10th level by the Old Dominion company; a cross-cut has passed through several veins and it is expected that it will soon cut the Maggie vein.——At the Old Dominion mine, the water problem in C shaft has been disposed of satisfactorily; connection with the 9th level will soon be made. In the western part of the mine a cross-cut is being driven on the 15th level. On the 16th level, 30 tons of sulphide ore carrying 3 to 5% copper are being extracted daily.

GRAHAM COUNTY.

Excitement has been created in Safford by an assay of ore from the Graham mountains; J. C. and William Robinson, the discoverers of the lode, claim that it is 17 ft. wide, and that the sample, which carried at the rate of $460 gold per ton, was taken across the vein.——Walter Doudna has let a contract to W. S. Riley to drive a 75-ft. adit at the Gypsy mine.——At the New York-Arizona mine development work continues to expose a fair-grade milling ore.——The New England company has completed the shipment of the Copper King ore that had been stored in North Clifton. Quite a number of carloads of ore are being

shipped from the Antietam mine.——At the Gold Belt mine gold ore of good quality has been found at a depth of 265 ft. in the shaft.

PINAL COUNTY.

A story comes from Phoenix that a certain mine situated within 1000 ft. of the Two Queens mine and owned by H. B. St. Clair, H. H. McNeil, and others, yields a particularly choice variety of gold, known as emerald green or Roman gold; it is said to be used mainly by manufacturing jewelers for rings and other jewelry in which emeralds or diamonds are set. It is alleged that John Kavanaugh of Troy bought some of it from the former owners of the property and had a ring made of it; this ring when placed beside an ordinary gold ring appears to have a decidedly greenish tint. The property is developed by a 70-ft. shaft and a 40-ft. adit. A small force of men is to be put at work searching for more green gold.

YAVAPAI COUNTY.

(Special Correspondence).—W. H. Reiterman, secretary and manager for the Money Metals Mining Co., operating in the Big Bug district and also in the Black hills, reports development work progressing rapidly on the Big Bug property known as the Bordeaux group of claims. The work has been advanced 200 ft. in a drift on the 100-ft. level. The work of sinking in the main shaft is also being pushed, and a depth of about 165 ft. has been attained. About 300 tons of ore carrying gold, silver, lead, and copper (principally gold) have been taken out in development work, no stoping being done. This ore has been concentrated at the Arizona M. & M. Co.'s mill, which is situated about 1½ miles below the Bordeaux mine. The concentrate carries approximately $102 gold and 9 oz. silver per ton, and 31% lead. The concentrate will be shipped in a short time to Needles, Cal., for final treatment.——Considerable development work is being done in the Copper Basin district, a number of properties being worked under bond and lease.——That interest in mining has not diminished in Yavapai county is evidenced by the large number of locations and affidavits of assessment work that are daily being filed with the County Recorder.

Prescott, Jan. 31.

At the Savoy mine, in the Bradshaw mountains, the retimbering of the adit is in progress.——E. A. Haggott is preparing to resume work at the Howell group of mines in the Santa Maria district.——The Redman M. & M. Co. has ordered an air-compressor and air-drills, which are to be delivered at the mine at once.——The Hydraulic Gold Mining Co. has taken over the placer mines of the Messicks estate on Lynx creek and has placed an order for machinery to handle 1000 cu. yd. of gravel per day.——Two companies are now operating machines on the San Domingo placers; it is expected that 10 machines will be in operation shortly.

YUMA COUNTY.

It is reported that eastern people are organizing a company to work the silver mine of J. C. Reed in the Harqua Hala mountains.——R. K. Humphrey and Charles H. Fay intend to begin work at once on the Rattlesnake and Extension claims, which adjoin the North Star property; the ore on the Rattlesnake claim is said to carry $10 per ton.——Supplies are being hauled to the property of the Great Western Mines Co. in the Bill Williams Fork district.

CALIFORNIA.

BUTTE COUNTY.

A depth of 35 ft. was reached in the first three days' work of the drill at the diamond mine. Slow progress was made at first owing to cemented gravel, but later the drill was working in sandstone and good progress was being made. Visitors in searching at the dump of the main shaft on the property have found a number of stones closely allied to diamonds.

CALAVERAS COUNTY.

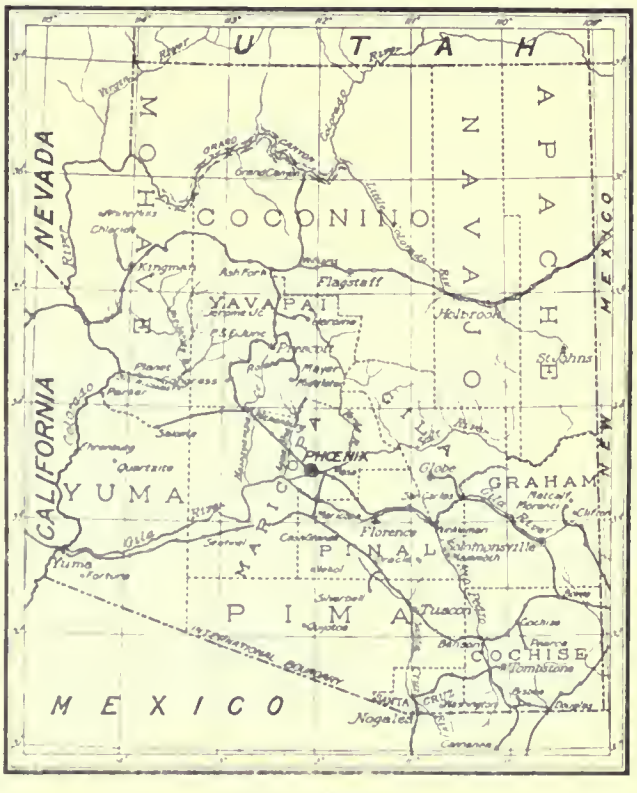
The Lightner Mining Co. has 60 stamps crushing ore; the ore can be mined, milled, and chlorinated for the sum of $2 per ton.——The Utica mine is starting up again after five months' shut-down on account of a strike, three months spent in unwatering the mine, and a month of delay caused by an accident in the shaft.——At the Angels mill 20 stamps are dropping.

EL DORADO COUNTY.

Work has been resumed at the Jones Hill mine in the Georgetown district; W. S. Kerr is superintendent.——The Warner ranch has been purchased by Koster & Berff for mining purposes.——Pipe is being hauled to the California Mohawk mine in the Fairplay district; the restraining dams are nearly completed.——B. F. Hartley, the superintendent of the Three Stars mine in Placer county will have charge of the Zantgraf mine.

INYO COUNTY.

A 600-ft. adit is being driven under contract at the Skookum mine near Benton; C. T. Julihn is superintendent.——A contract has been let for the Keeler-Skidoo road.——Chicago capitalists have purchased a property in Pleasant canyon near Ballarat; they intend to begin development soon.——It is reported that at Anvil Springs a strike



Map of Arizona.

of considerable importance was made recently by a Mr. Rush, who claims to have a vein 14 in. wide of ore assaying $275 gold per ton; the ore is being sacked for shipment by way of Johannesburg.

NEVADA COUNTY.

The new adit at the Belle Union mine is now 175 ft. long.——At the Normandie mine on Deadman's Flat men are getting the machinery in shape for sinking a shaft. A new steam hoist and pumping plant have been installed; the plant is to be operated with oil as fuel.——On the 1000-ft. level of the Murchie mine the west drift of 500 ft. exposes a vein that averages 4 ft. wide. About March 1 sinking will be resumed and later a level will be opened at the depth of 1100 ft.; 50 men are working on the property and the 20-stamp mill is crushing good ore.——At the Conlan mine the adit which is being driven to cut the vein at depth is expected soon to break into high-grade milling ore. In the old shaft some ore assaying as high as $23 per ton has been found, but it does not mill freely; H. G. A. Brunnier is general manager.——J. F. Littlefield has purchased the Fish Pond placer property, which extends for 5000 ft. along Greenhorn creek below Quaker Hill; it is reported that he intends to dredge it.——A body of high-grade milling ore has been found in the west drift of the Union Hill mine; Clifford Graham is manager.

PLUMAS COUNTY.

Frank Sorsoli, Edward Abbott, and Frank Spring have made another payment on the Halstead mining property, 8 miles from Spanish Ranch; the lode is supposed to be in places 60 ft. wide and to carry $1 to $20 gold per ton, besides 2% of sulphides which upon being concentrated assay as high as $2800 per ton. The lode is developed by a series of adits.

SAN BERNARDINO COUNTY.

The development of the new camp at Hart continues; excitement is running high. Thirty-five leases have been let and 200 men were expected to begin work Feb. 1. Foster Bros. in their cross-cut on the Oro Belle mine have found a small orebody a foot wide that is said to carry at least $1000 per ton; a burro train is packing it in sacks down to the office. Specimens covered with gold will assay at the rate of $10,000 per ton.——At the Todhunter, Felix, and Aldrich leases ore fairly covered with gold is being taken out in small quantities.——Hart & Hitt are sacking ore from the original discovery and the Oro, Lee Foster, and Goldfield Big Chief companies are shipping ore.——A contract has been let for the daily delivery of 8000 gal. of water into the town of Hart; the pipes for the water-line are at Barnwell.

SHASTA COUNTY.

Two months ago F. M. Leland purchased the Washington mine near French Gulch; he has given the mill and other machinery a thorough overhauling, has put in new plates and two new concentrators, and is building new boarding and bunk houses. There are 25 men employed at present.——The Sacramento Valley & Eastern railroad is completed as far as Horse creek and will reach Delamar in a short time.——The electric iron smelter at Heroult started again on Jan. 29. When started three weeks ago the walls of the furnace showed signs of cracking open and certain improvements were found necessary.

SIERRA COUNTY.

H. L. Johnson has resumed work in the lower adit of the El Dorado mine.——At the Tightner mine the lower adit is being driven rapidly; a flow of water recently rendered it difficult to spit the fuses, this water draining from the old shaft, which is now dry.——The Rainbow mill is running steadily on high-grade ore; 20 men are employed in the mine and mill.——At the Red Star mine reopening the old adits is rapidly advancing; about 1400 ft. has been completed. Ed Brindle is superintendent.——The Alleghany Mining Co. is operating its hydraulic mine at Chipps Flat under a permit issued by the United States Debris Commission.——At the Plumbago mine a modern lodging house has been built; it includes bath-rooms and electric lights. M. W. Mather is superintendent.——At the Deep Blue gravel mine, just below Alleghany a force of men is developing the quartz vein recently discovered there; the high-grade ore is being hauled to the El Dorado mill; S. M. Weiland is superintendent.

SISKIYOU COUNTY.

Last fall W. C. Stanley and L. F. Coburn bought a gold prospect near Hawkinsville, erected a 2-stamp mill, and in 20 days took out about $2500, the ore milling nearly $28 gold per ton. About 20% of the gold content goes into the concentrate. The owners are trying to raise money for additional equipment and development.——Nickel ore is reported to have been found at the base of Mt. Shasta, about two miles from Sisson.

TUOLUMNE COUNTY.

The repairs on the Calmas mill at Tuttletown being finished, 10 stamps are now dropping on ore from the 100-ft. level of the Calmas mine.——Conlin Bros. have men at work replacing the pipe-line from the Tuolumne water-ditch to their Experimental Gulch mine; the new pipe is 8-in. diam. and will be 3000 ft. long. Thirty tons of ore from the Sullivan Ranch mine crushed at the Santa Ysabel mill for J. W. McGinn is reported to have yielded about $13 per ton.——J. T. Thompson and F. E. Drew have been arrested on the charge of stealing amalgam at the Smith mine near Columbia and at the Clio mine near Jacksonville. In their baggage there was found a tobacco sack filled with amalgam, and also tools which may have been used in robbing the plates.——H. M. Stanley has shipped 200 lb. of ore from No. 9 mine, at Groveland, to San Jose to be tested.——John Vincent and W. D. Mullins are said to have a splendid prospect on a 'pocket' claim located on the Vincent ranch near Tuttletown.

COLORADO.

CLEAR CREEK COUNTY.

Great interest was manifest throughout the upper Clear Creek district when the announcement was made that the new mill of the Empire Gold M., M. & T. Co. was to be put into commission. This is the first time in the history of mining in the northern Colorado mining region that the Hatheway gyratory mill has been tried, and naturally owners of mines in the sulphide belt of the upper Clear Creek district were interested.——At the Nabob mine on Columbian mountain, at a distance of 250 ft. from the entrance of the adit started a few weeks ago, a streak of high-grade silver-lead ore, 6 to 8 in. wide, has been exposed. The work under way is being performed by Lovell, Taylor & Co.——A shipment of several tons of ore from the Riley lease on the Sunburst mine returned 505 oz. silver per ton. ——At the Centennial mine, stoping is in progress on an orebody 10 to 16 in. wide that carries $35 in gold and copper per ton.——Machine-drills having been brought into use by the Marshall-Russell Gold M., M. & T. Co. at its mine near Miller mountain, the adit is being driven steadily ahead; it is now over 1100 ft. long.

SUMMIT COUNTY.

The American Zinc Extraction Co. has agreed to buy the Little Sallie Barker group of six claims in the Bevan district from A. W. Phillips and T. A. Brown for $20,000; part of the purchase price has been paid.——There is only one shift working at the Daly Judge mill, but a good output is being maintained from the mine.——In the shaft-house of the New York Bonanza mine a lot of first-class ore is being sacked for shipment.

TELLER COUNTY.

(Special Correspondence).—Work is progressing as rapidly as possible on the Cripple Creek drainage adit. Beginning today A. E. Carlton will have charge of the work under contract. So far about 1400 ft. has been driven, or on an average of about 200 ft. per month. Wm. Bainbridge has charge of the work and T. R. Countryman is engineer. ——The W. P. H. Leasing Co. has made a successful run on Jerry Johnson dump ore and are temporarily closed down for some changes and installing new machinery to handle the material as it is brought to the mill. A hoist and car system is being installed. Only 50 tons per day is going through the mill at present but this is to be increased to 100 tons shortly. W. A. Reed is manager.——Thos. Kavanaugh is handling ore from the Ramona mine through the Wild Horse mill. The ore averages about $3 per ton and 95% is saved by cyaniding 50 tons per day, without roasting. The Ironclad mill, better known as the Little Homestake, is handling 100 tons per day of $1.80 to $2 ore, saving 85%. To mine and put in the mill costs 30c. per ton and milling costs 80c. per ton. Another vat has recently been installed; this will increase the capacity to 120 tons per day. B. H. Liener is manager and C. E. Hart superintendent of mill.

Cripple Creek, Feb. 1.

The production from the Cripple Creek district for January broke all records for 31 days during the past three years; the total ore handled amounted to 58,785 tons, of a gross value of $1,335,820. The Golden Cycle mill at Colorado City handled 20,300 tons, and the U. S. R. & R. Co. 17,500 tons.——Now that the workings on the 1000-ft. level of the Gold Coin mine have been drained, the management will commence stoping the high-grade ore that was developed before the workings were drowned out several months ago. Although of small size, the orebody is extremely rich and contains a narrow streak of sylvanite ore that

carries 20 to 50 oz. gold per ton.——W. J. Hill and associates, lessees at the Pharmacist and Wrockloff claims on Bull hill, have made a settlement with the operators of the Golden Cycle mill on two consignments of ore sent recently; one lot of 20 tons returned $118.70 per ton and another lot of 47 tons returned $29.30 per ton.——McBride and associates, lessees at the Morning Glory mine on Raven hill, made a 20-ton shipment of medium-grade ore to a local sampler.——Merrifield & Co. have begun operations on the old Pike's Peak claim adjoining the Lucky Gus No. 2 claim on Bull hill; they will drive a cross-cut on the 300-ft. level east of the shaft.——The Rigi claim of the Rigi Group Gold Mining Co. on Battle mountain is the scene of the latest strike of particular importance to the Cripple Creek district generally. An ore-shoot was opened by lessees three weeks ago, but only two shipments of medium grade ore were made from the property. The vein is from 1 to 4½ ft. wide and carries 1½ to 3 oz. gold per ton.

NEVADA.

ESMERALDA COUNTY.

Governor Sparks signed the Nevada police bill on Jan. 28. It is expected that the police force can be organized and made ready for business in 20 days. It is said that Captain W. L. Cox, of Reno, is to receive the appointment of superintendent; he has the military experience necessary for the place. The withdrawal of the card system by the Goldfield Mine Operators Association does not affect the original policy of the operators in the employment of union or non-union miners, for although under the open-shop plan, the only recommendation a miner needs to secure employment is proof of his competency and reliability; the agitators of the Western Federation of Miners would be unable to furnish such proof and hence could not secure work. Apparently the domination of the Western Federation is a thing of the past in the Goldfield district, as the union will receive no recognition whatever from the operators.

The Consolidated and Florence companies will not hurry to put on a big force of men. Nothing will be done on company account in the way of mining at the Florence mine until the new mill is ready to work. No effort will be made for a big production at the Consolidated property until the new model reduction plant is completed next fall, as railway and smelter charges are too high.——Work at the Oro mine was to be started on Feb. 5, with the intention of sinking the shaft to a depth of 500 ft.——A small force of men has been cleaning drifts on the Florence Leasing & Mining Co.'s ground.——The Garrett lessees at the Kendall mine have taken a lease on the Kinkead mill to treat the low-grade ore which has accumulated on the dump; at the Garrett lease there are also large bodies of milling ore blocked out that will keep the mill running to full capacity for many months.——The first shipment of ore from Stimler consisted of 10 tons from the Watson-Irvine mine.——The Rawhide Regent company has a small force of men driving a 50-ft. adit to cross-cut its vein on the south side of Nil Desperandum peak; G. T. Milliner is general manager.——The Wild West lease being operated by the Grutt Bros. continues to yield specimen ore of great richness from a vein 18 in. wide.——At the Butler-Hunt lease on Balloon hill, Harry Butler while prospecting on the surface found some rock that assayed well.——Cotter, Conners, McGettrict & Marshall have found on the Luning lease a body of ore containing a 1-in. streak that assayed over $19,000 gold per ton; this has been followed to a depth of 35 ft. and found to perceptibly widen.——Shipping ore is piling up at the workings of the old Loftus & Davis lease on the Sandstorm mine, which is now being operated by M. C. Scully.——Ore carrying $15 to $40 per ton is exposed on the 150-ft. level of the Blue Quartz mine.——At the Quartzite Annex mine, the working shaft is being sunk from the 75-ft. to the 300-ft. level.

LYON COUNTY.

It is stated that J. H. Hill is making arrangements to dredge the Carson river for the millions of dollars worth of amalgam that is supposed to lie along the bottom of the stream.——Preparations are in progress for an early resumption of work at the Western Nevada copper mine.——It is announced that the owners of the Nevada-Douglas and Ludwig mines are planning the construction of a smelter and of a railroad from the mines to Wabusca.——Another rich strike of gold ore is reported from Mountain View; the Mason Valley Mining & Leasing Co. has found on the Big Twenty claim a 1-ft. vein of ore that is said to carry $128 gold per ton. This ore is being sacked for shipment.——Fred Flindt has secured a small bar of bullion by milling ore from the Wheeler mine.——At the McConnell mine 17 more miners were recently engaged.

NYE COUNTY.

The total output of the Tonopah mines for the week ending Jan. 31 was 3921 tons, of an estimated value (the shipping ore being valued at $60 per ton and the milling ore at $20 per ton) of $82,060.——The Belmont mill was closed down for two days during the week, to make connection with the Nevada California Power Co., whose power it will use from now on. The amount of ore handled by the mill was on that account somewhat curtailed. Work is progressing systematically on the different levels of the Belmont mine; on the Occidental claim a body of ore 3 to 3½ ft. wide has been found in the South vein.——Six machine-drills are at work in the Jim Butler mine and work is progressing on all the levels.——A test run of 100 tons of ore is being crushed by the Yellow Jacket mill

New Hotel at Goldfield.

at Gold Hill.——The Round Mountain Hydraulic Gold Mining Co. cleaned up between $7000 and $10,000 on Jan. 22. The directors of the company have decided to purchase $20,000 worth of pipe to complete the Jefferson Canyon system of conduits.——The Manhattan Milling & Leasing Co. is erecting a 2-stamp mill on the Buckboard claim in close proximity to some of the rich leases on Litigation hill; this will be Manhattan's fourth mill.——There is a story that a new free gold district has been found in the northern part of the county, near the mouths of Becker and Barrett canyons on the north side of the Reese River valley, about forty miles southwest of Austin. It is said that several veins from 5 to 25 ft. wide, carrying $15 to $200 per ton, have been opened, and that many stringers from 1 to 5 in. wide carry $100 to $4000 per ton. On the Lost Treasure group of claims there is said to be a 25-ft. vein that carries an average of $20 per ton. The Peterson Bros., it is alleged, recently secured $8800 by mortaring in a single week.——A body of ore 10 ft. wide has been cut in a cross-cut on the 300-ft. level of the Denver mine of the Tramp Consolidated Co. at Rhyolite. A Blake crusher and a 200-ton cyanide plant will be installed for the Bullfrog Pioneer Leasing & Milling Co.; in the mine there is sufficient ore in reserve to keep the plant in operation for many months.——Supplies and men have been taken to the Keane Wonder Extension mine to start devel-

opment work.——The annual report of the Tecopa Consolidated company shows that the ore shipments from August to Jan. 1 amounted to 7453 tons, which yielded $113,667 over and above smelting and transportation charges. The cost of mining averages $2 per ton; the ore being shipped carries about $25 per ton.

Stoping for ore is progressing as usual at the Tonopah Extension mine; good progress is being made in the north cross-cut on the 1050-ft. level.——At the MacNamara mine the working force has recently been increased. A raise has been driven up 80 ft. in high-grade ore.——The adit of the Round Mountain Monster Mining Co. has cut a series of veins that are from 3 to 5 in. thick and are said to be high-grade tungsten ore.——At the Sunnyside mine the vein has been cut in the shaft at the 350-ft. level; this adds much to the ore reserves.——At the Sphinx mine a Huntingdon mill and boiler have arrived from Austin and the erection of the mill is now in progress.——The conflict between the Manhattan Earl Mining Co. and the Manhattan Consolidated Union No. 2 Co. has been satisfactorily adjusted; the former company gets the disputed territory. ——The Montgomery-Shoshone mill at Beatty is treating 200 tons of ore per day; the output is estimated at $75,000 per month.——A carload of ore has been shipped from the Diamond Queen mine; this ore is said to have carried over $200 gold per ton.

WHITE PINE COUNTY.

(Special Correspondence).—The Boston-Ely Development Co. about fifteen months ago acquired a group of claims comprising approximately 180 acres adjoining the Cumberland-Ely holdings on the west. This part of the Cumberland-Ely property was formerly the Veteran-Ely ground. In the Veteran mine there is blocked out an immense tonnage of what is said to be the highest grade sulphide copper ore in the district. The orebody is very persistent in a westerly and northwesterly course, but the oxide zone becomes deeper in that direction, so that the lowest drift ran out of and apparently over the ore, which dips westerly at a rather steep angle. In Boston-Ely ground the porphyry plunges beneath the limestone. The company has penetrated the limestone with churn-drills and ran down through 400 ft. of porphyry, but did not get through the oxidized zone. A shaft being sunk 300 ft. north of the point at which the drilling was done is 650 ft. deep and has not reached the base of the limestone. In a cross-cut which was driven north on the 600 ft. level a fractured zone was found to carry a small quantity of the precious metals. This vein matter strikes toward the Veteran orebody and may be an offshoot from the main porphyry belt. The company was recently re-organized and is now known as the Boston-Ely Mining Co. The shares of the company have risen from 60c. to $3.65 in the last three days.

Kimberly, Jan. 17.

The announcement has been made that the Nevada Consolidated Copper Co. has decided to issue bonds in the sum of $2,000,000; they will bear 6% interest and will be convertible at the option of the holder to stock of the company at the rate of $10 per share. This will furnish money for the completion of the reduction plant at McGill. W. A. Perkins, general superintendent of construction work at McGill, engaged 500 men in Salt Lake City to assist in the early completion of the plant.——P. H. Cannon and others have conveyed the Flagstaff mine near Cherry Creek to the Cherry Creek Mines Co. for a stock consideration.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The fifth carload of ore has been shipped by the lessee of the Insurgent mine. Five men have been employed on the lease, but work was suspended six weeks because the smelters could not take the ore; since resuming work the five men took out four carloads of ore in four weeks, two of which were side-tracked on the railway until W. M. Crummer, the lessee, induced the Granby smelter manager to accept them. The other two carloads are in transit, the estimated average value of the last one shipped, from a bunch of ore on the foot-wall, being nearly $100 per ton. The Insurgent mine is located on the eastern extension of the Lone Pine vein, and the lessee has the privilege of working it through the lower adit of the Lone Pine workings.——The Syndicated Deep Mines Co. has a small force of men overhauling the machinery of the Pearl Consolidated Mining Co. on the Lone Pine claim and expects to begin pumping the water out of the shaft about Feb. 4.——At the annual stockholders' meeting of the Oversight M. & M. Co., held at Republic Jan 25, the following directors were elected: Harold Preston, E. M. Carr, Wm. Martin, C. A. Wallace, Chas. E. Murphy, E. J. Delbridge, and S. G. Dewsnap.——The machinery at the Copper Key mine is now in splendid condition, and the compressor is furnishing all the air that is needed to run two machine-drills. The adit is now 269 ft. long.—— The Colville M. & S. Co. is arranging to haul two rotary furnaces to its South Half group of claims at Park City on sleds, while sleighing is good.——The adit lately started on the Dominion group of claims, in Keller district, is in 60 ft. and gaining a foot per day.

Republic, Jan. 31.

OKANOGAN COUNTY.

(Special Correspondence).—At the Unga mine near Wauconda the lower adit is being driven to cut the vein. The management reports having struck good ore in the shaft. ——A large body of valuable ore has been uncovered in the Gold Dust mine, adjoining the Bodie mine, and the company anticipates making a shipment in a week or two.—— The Gold Creek Antimony Mines & Smelter Co. of Wichita, Kansas, operating a valuable antimony mine in the Twisp district, has ordered seven carloads of machinery for its mine and mill.——The Hidden Treasure mill at Twisp has resumed running, after being closed down for several weeks. The company's mine has been operated continually with two shifts; ore is being hauled to the mill on sleds. ——A 2-hp. gasoline engine and small air-compressor have been installed at the Alder mine, to be used for forcing air to the head of a 500-ft. adit, where two shifts of men are at work.

Republic, Jan. 22.

CANADA.

BRITISH COLUMBIA.

The ore shipped from and crushed at the mines of the Rossland district for the week ending Jan. 25 was as follows: Centre Star, 3610 tons; Le Roi, 1540; Le Roi No. 2, 630; Evening Star, 70; total, 5850 tons. At the smelter of the Consolidated company at Trail there was received during the week 4941 tons of ore. Besides that from Rossland mines, shipments were received from other mines as follows: St. Eugene, 351 tons; La Plata, 133; Emerald, 45; Sunset, 20; Arlington of Erie, 77; Evening Star, 27; North Star, 66; Vancouver, 42; Whitewater Deep, 48; New Jerusalem, 32; Richmond Eureka, 20; Bluebird, Sandon, 18; Eva, 56 tons. The following are the district shipments for the week: Boundary, 18,075 tons; Rossland, 5850; Slocan-Kootenay, 3029; Total, 26,954 tons.——A 20-hp. electric hoisting plant has been installed by the Greenwood City Waterworks Co. at the Tiptop mine in Skylark.——At the Rob Roy mine, on Wallace mountain, high-grade ore 18 in. wide has been found.——The Granby Consolidated M. & S. Co. has succeeded in getting its seventh furnace in blast. ——The superintendent of the Jewell mine at Long Lake is in Colorado, where he is investigating methods for the treatment of Jewell ore.——At the Crescent mine 10 men are driving on the 225-ft. level; it is likely that ore shipments to the Trail smelter will be resumed during this month.——Four carloads of ore have been shipped from the Emerald mine to the Trail smelter this year.

Work has been continued steadily during the winter at a number of copper mines in the White Horse district, including the Volerie, Arctic Chief, War Eagle, Empress of India, and Josephine.——The Tatlayoco Lake Copper Co. is driving an adit to develop a copper-bearing vein on its property about 150 miles north of Vancouver. Recently a gold and antimony-bearing vein was found on the same property; development of this will be begun in the spring.

Special Correspondence.

LONDON.

The Diamond Market.—Artificial Diamonds.—Depression in Kaffirs.—Dolores Limited.—Tin Ticketings.—Mining in Cornwall.—Market for Tin Ore.

The diamond share market continues to cause anxiety among shareholders and those interested in the trade. All sorts of rumors are afloat. It is even said that the Premier mine is to close down for a time, but this is emphatically contradicted. Rumor is also rife that there are difficulties which prevent an amicable arrangement between the De Beers and the Premier companies for the purpose of restricting production and maintaining prices. Those who control the trade will almost certainly be able to come to some agreement on this subject, and it is hardly likely that we shall see any cut in prices. I believe, however, that it is quite time that some reduction was made in the price of both uncut and cut diamonds. The price of a first-class diamond is higher now than it was before the great production commenced in South Africa. Twelve pounds per carat for small stones is far too much to have to pay, and a reduction would revive buying in many quarters. But, as I say, a reduction of output and not a reduction of price will almost certainly be the policy. The diamond market has had an element of comedy this week, in the action brought by Sir Julius Wernher in the French courts against Mr. Lemoine. The daily papers have naturally made the most of this incident and have decked out the story to suit the popular taste. The facts of the case are that some time ago Mr. Lemoine brought his alleged process for producing artificial diamonds before Sir Julius Wernher, who personally inspected the electric furnace in which the diamonds were made. Sir Julius asked Mr. Oats of the De Beers company to investigate, but as his report was unfavorable to the process, the matter dropped. Sir Julius had provided the inventor with considerable funds and this sum he was content to lose without publishing the matter to the whole world. However, when he found that Mr. Lemoine was proceeding with his work and conducting operations on a still larger scale, apparently with his (Sir Julius's) money, it was thought advisable to bring an action in the French court with the object of recovering some of the money, on the plea that it was obtained by false pretences. The outcome of the action is awaited with interest. The reason Sir Julius Wernher was induced to look into the invention was to see if the process was likely to interfere with the diamond mines. I believe as a matter of fact that Mr. Lemoine actually does produce tiny crystals, but he claims to produce big ones, which the prosecution allege to have come from Jagersfontein.

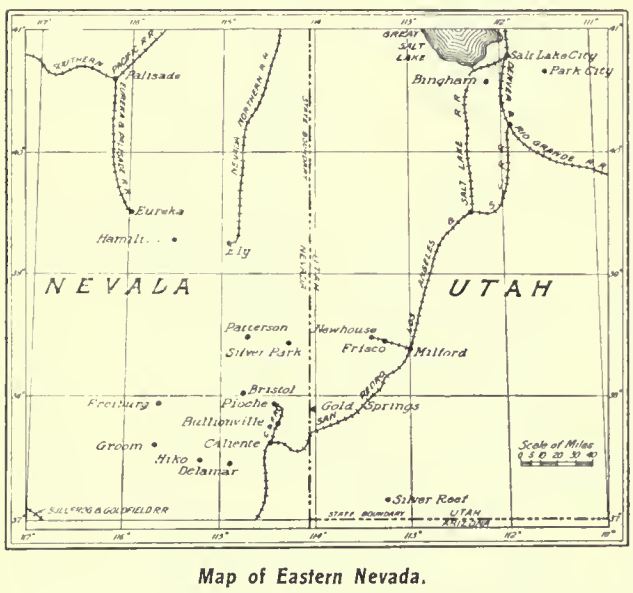
In spite of the record output of gold, particulars of which you have published, the South African market is far from lively. Naturally the diamond crisis affects other sections of the market. Then again we have had an issue of Cape of Good Hope colonial stock, and following this, Mr. J. B. Robinson is asking his shareholders to provide a million pounds more capital for the purpose of equipping the Randfontein group of mines. This issue has been somewhat sudden. Whether the money will be raised remains to be seen, but it is hardly likely that the response will be general. The Randfontein Estates Co. owns twelve mines, four of which are producing and the remaining eight sufficiently developed to warrant the erection of plant. It is intended to provide 600 stamps altogether and to work the mines in groups. The output of these stamps will be about 126,000 tons per month, and it is estimated that the profit will be about 10 shillings per ton. The new issue of shares consists of a million preference shares of participating certificates, entitling the holders to 6% preference dividend, and ranking equally with the ordinary shares as regards the balance of divisible profits. The issued capital originally, in 1889, when the company was formed, was £2,000,000. In 1899, 500,000 more shares were issued and in 1902 another 500,000 were disposed of, buying up the capital of £3,000,000. The issues of 1899 and 1902 were made at considerable premiums, the one-pound share being sold at £3. The present state of the money market can be well judged when this change from ordinary shares at a premium to participating certificates has had to be made.

It has been decided to wind up the English company called Dolores Limited and in future to place the entire management and control in the hands of the American company of similar name. It will be remembered that the English company was formed in 1904 by the Venture Corporation for the purpose of acquiring the shares in the American company registered under the laws of Maine and owning the Dolores mine in the Guerrero district of Chihuahua. The idea of the English flotation was to sell the shares in the English company in England, but for one reason or another the shares passed mostly into the hands of the Americans who were in control of the American company, and at the present time nine-tenths of the shares are held in America in this way. It is obvious that under the circumstances there was no argument in favor of maintaining the English organization; therefore, the company is to be wound up. It is a pity that this interesting and promising mine should have gone back to America.

The figures for the output of tin in Cornwall during 1907 are not available, but a very good idea of the output can be obtained by the amount of tin concentrates sold at the fortnightly tin ticketings. These ticketings are held at Redruth, where the five smelters bid for the various parcels offered by the mines. The total amount of concentrate sold in this way at the 26 ticketings in 1907 was 5720 tons and the price received by the mines was £593,704. During 1906 there were 27 ticketings and the amount sold was 5973 tons, realizing £626,780. Allowing for the difference in the number of ticketings, it will be seen that the output and average price per ton for the years were to all intents and purposes identical. The average price obtained for the concen-

trates at each ticketing during 1906 did not vary greatly and ranged from £97 to £114, without any violent fluctuations. During the first nine months of 1907 the prices obtained at the ticketings continued at a high level, never falling below £100 and for some months in the spring ranging from £115 to £120. After the end of September, the memorable collapse in the price of tin set in and the average prices at the last two ticketings in the year fell to £72 and £75. The future course of prices is none too promising.

It is a noteworthy fact that mines recently reopened or re-modeled have not yet redeemed their promise of increasing the output. The old stagers, like Dolcoath, Carn Brea, Basset, East Pool, Grenville, West Kitty, South Crofty, and Levant still constitute the backbone of the industry. Clitters only sold 125 tons of tin concentrate in 1907. Of



Map of Eastern Nevada.

all the recently re-opened mines, the Wheal Kitty in St. Agnes district has done the best and the credit for the good work is due to that sound and patriotic Cornishman, J. H. Collins. While younger men with modern ideas and plentiful supplies of capital at their backs are meeting with all sorts of difficulties that postpone the production of concentrate, Mr. Collins is regularly selling his six tons every fortnight, although he is short of working capital and uses old and so-called out-of-date machinery. As already mentioned, the total output of tin is not easily estimated, for the metallic contents of the concentrates sold cannot be actually ascertained. Perhaps three-quarters of the amount sold will average 66% tin. The remaining quarter consists of lower-grade concentrate and concentrate that contains metals subject to a penalty. In addition to the concentrate sold at the ticketings there are also products from the steam-tin works that are sold privately. These concentrates are not of high grade, and probably contain less than 50% metallic tin. The amount of concentrate produced in this way usually adds about 10% to the total production, so the output of concentrate during 1907 will work out at about 6200 tons, of which the average metallic contents obtainable by smelting will be about 60%. As above mentioned there are five smelting firms that bid for the ores. During 1907 Williams, Harvey & Co. of Hayle took the largest quantity. The Chyandour, at Penzance (owned by Bolitho), and the Cornish Tin Co., at Redruth (owned by Alfred Lanyon), followed next, while Bain's, at Redruth, and the Penpoll, owned by Strauss, on the river below Truro, took smaller quantities. No Cornish ores ever go anywhere else to be smelted. On the other hand, considerable quantities of foreign ores, from Bolivia, the Straits, Swaziland, and elsewhere, come to Cornwall for treatment, and the smelters themselves are shareholders in tin mining companies operating in the Straits and South America. The Penpoll smelter depends chiefly on Bolivian ores.

PIOCHE, NEVADA.

A Crisis Passed.—Resumption of Work.—Nevada Utah Co.—Ohio Kentucky Co.—Diamond-Drill Exploration.

Pioche passed a crisis. Owing to the decline in metal prices and the practical collapse of the ore market, the mine-owners of the camp had formed a rather loose agreement to adopt a lower scale of wages. The Miners Union protested against this and finally voted not to go to work. Nearly all operations had stopped and the outlook was for a period of paralysis. On January 6 a compromise was reached and a revised scale adopted. This gives hoist-engineers, mine-blacksmiths, and timber-framers each $4 per day; machine-men and their helpers, tool-sharpeners, and timbermen, $3.50; hand-miners, $3.25; dry-shaft work, 50 cents a day more than drifting; wet-shaft work where the miner furnishes his own waterproofs, $1 extra, and where the company furnishes them, 75 cents; minimum underground and surface wage to be $3 per day.

The Nevada Utah started up at once when this compromise was effected, and other properties have been gradually falling into line. James P. Gaskill, chief engineer of all the Nevada Utah properties in both States, came the latter part of December and L. W. Wiekes, the superintendent, followed him on January 2. They started the Day mine at Jack Rabbit and immediately began shipping a car of ore per day. That is a low-grade mine with an enormous tonnage. Under present conditions the returns were so low that Mr. Gaskill at once entered into negotiations with the Clark railroad for lower rates and these have just been announced. From Pioche to the Utah Valley smelters the rate on ores of $10 net value or under (assay-value, less smelter charges) is to be $3.25 per ton, and for ores between $10 and $15 the rate is to be $3.50. This is a concession from the present tariff of 75 cents and 50 cents respectively. In the discussion about a lower rate than $4 per ton on very low-grade ores, much has been said about the rate of $2.75 per ton on $12 ore from Eureka, Nevada, to Utah Valley smelters. In making comparisons of this kind one must not overlook the profile of the railroad that carries the ore. Between Pioche and Salt Lake the vertical height to which a car of ore must be raised aggre-

gates about 3250 ft., while from Eureka to Salt Lake it aggregates less than 1500 ft. The mileage is practically the same. Against this advantage of grade between Eureka and Salt Lake is the fact that ore from Eureka must be trans-shipped at Palisade from narrow to broad-gauge cars. Mr. Gaskill is negotiating for another engine for the company's private line between here and Jack Rabbit, and as soon as that arrives it is the purpose to ship not less than two hundred tons a day from that point.

The Ohio Kentucky resumed work last Sunday with its old force. No report has come from the negotiations at New York looking to the admission of the Ohio Kentucky to the consolidation being formed to take in the Nevada Utah, Balaklala, etc. The Nevada Utah has long been threatening to bring an apex suit against the Ohio Kentucky, claiming nearly all of the vein thus far disclosed in their workings. This controversy would be avoided by a consolidation. The situation exemplifies once more the folly of keeping our idiotic law of apex on the statute books. Each case tried brings out some new condition not previously in evidence. This case, if it reaches the courts, will be no exception. It will be intensely interesting to students of legal jurisprudence, but an unmitigated evil in its effect upon the activities of this camp. From that standpoint consolidation would be a blessing.——The Prince is to start up again in February. The Bristol Consolidated is perfecting arrangements to work again.—— The Lincoln-Nevada, Nevada Pioche, Boston & Pioche, Nevada Horn Silver, Pioche Demijohn, Pioche Milwaukee, California Pioche, Pioche Mohawk, Pioche X Ray, Pioche Mines, Last Chance, and Lucky Star companies are all working with small forces and most of them are taking out some ore for shipment. The Mendha is only waiting for an ore market to begin shipping at least a car per day. The Ely Valley Mining & Milling Co. is a corporation recently financed in London to take over the old Harrison Eilers property about three miles northwest of Pioche. They are sinking on a strong vein that has yielded good ore from the shaft, which is down 125 feet.

James Nesbitt and his associates are working their property called the Gypsy Group, in the Highland district, not far from the Mendha. They are getting out some ore carrying up to 500 oz. silver.

The most interesting development in progress here today is the diamond-drill exploration by the Nevada Des Moines Co. They have a claim on the eastern edge of town on which they sank a shaft about 240 ft. Recently they drilled 250 ft. from the bottom of that shaft. The town of Pioche and the great mines on the hillside are on a strip of quartzite that was uplifted more than 1000 ft. above the alternating beds of shale and limestone. These beds are probably in approximately their original position at the Nevada Des Moines. The drill went through several layers of limestone and shale, and near the bottom entered what appears to be a rhyolite tuff. The very last of the core was ore of such grade that the management immediately ordered a 40-hp. gasoline hoist, with air-compressor and machine-drills. They give out meagre information, but the manager, D. C. Mahedy, tells me that the ore was of excellent grade and highly satisfactory. The Nevada Utah has just closed a contract with the same drill outfit for 5000 ft. of drilling. Altogether the prospects here now seem extremely favorable. Several new enterprises are nearing consummation, which cannot be mentioned yet, but which promise much for Pioche.

BUTTE, MONTANA.

Production Last Month. — Conditions Continue Gloomy.——Butte & London.—Parrot Shaft.— Butte & Superior Mortgage.

The estimated copper output of the Butte district in January was 9,057,250 lb. Only four companies were producing, in addition to a few lessees, as follows:

Companies.	Tons of ore.	Pounds of copper.
Boston & Montana	89,100	7,128,000
North Butte	4,000	480,000
Original	12,400	992,000
Pittsburgh & Montana	3,410	341,000
Miscellaneous	1,550	116,250
Totals	110,460	9,057,250

The Boston & Montana output represents the total production of the Amalgamated, as all the other properties of that company are still closed down. The ore mined by the North Butte is limited to the ore taken out in the course of development on the 1800 level. The Pittsburgh & Montana is treating about 110 tons of first-class ore mined from its own property and also handles a little custom ore. So far as can be ascertained in Butte there is no immediate prospect of a revival, except that the Original will increase its production as soon as the shaft of the Original mine is completed, it having been closed pending re-timbering. Financial conditions are tightening, rather than relaxing, as regards some of the new companies that have been trying to maintain development work. The companies are rich in treasury stock, but the stock can not be sold now except at a sacrifice.

The Butte & London Copper Development Co. is still doing exploratory work on the 1100-ft. level, and is driving on two veins, the most promising of seven veins that have been cross-cut. While some good assays—about 4 oz. silver and 2.5% copper—have been taken from the vein, it is becoming evident that greater depth will be required to get to profitable ore. H. V. Winchell, chief geologist for the Great Northern Railway and formerly with the Amalgamated Copper Co., made a report in which he said that he knew of four veins that traverse the Butte & London ground, but the company has found seven veins within 500 ft. of the shaft. They are from 6 to 20 ft. wide. The chairman of the Venture Corporation is on his way from London to meet the officers of the company. The Venture people have made several overtures to get control of the Butte & London, and it is considered probable that the deal will be consummated at the approaching meeting.——A report of the December operations

on the Barnes-King states that about 4000 tons of ore were mined and milled that month, the gross value being under $4 per ton, which did not pay.

MEXICO.

San Toy Affairs.—Railroad Freight on Ore.—Tezuitlan Smelter Business.—Conditions in Oaxaca.—Tehauntepec Silver Mines.—Oil in Chihuahua.

An important change has been made in the operative force of the San Toy Mining Co., Santa Eulalie district, Chihuahua, due to a practical re-organization of the company. R. R. Brown, of Pittsburg, has resigned as president of the company, and J. P. Hutchinson as general manager. Mr. Hutchinson was the real promoter of the company, and though he still remains as a stockholder, he now gives up all active connection with the company and will first give his time to the case which is now before the Supreme Court of Mexico City. This concerns the Dolores claim, which was held under titles dating back among the oldest in the Santa Eulalie district, but which were set aside and possession forcibly taken from Mr. Hutchinson on a ruling of the Court of the Fifth Sala in Chihuahua, based on some technicalities in the new mining laws, but whether rightly or not it now rests for the Supreme Court to decide. The holders of all old titles to mining properties in Mexico should side with Mr. Hutchinson in this suit. The offices made vacant by the resignation of Messrs. Brown and Hutchinson are at present both to be filled by Donald B. Gillies, recently from Tonopah, Nevada, but formerly for some years with the Clark mines at Butte. Mr. Gillies' experience, therefore, in the handling of large bodies of low-grade ore will be useful to him in his present position, for the San Toy, though having large deposits of iron oxide ore, is unusually low even for Santa Eulalie ores in both lead and silver, and it is already reported that the output is to be doubled as soon as possible, which will bring it up to between 300 and 400 tons per day.

The railroads are feeling the effects of the low prices of the metals, not only in the great falling off of shipments by reason of the curtailment of production in all directions, but also in the question of increased freight rates, for which they have been urgently seeking. As has already been stated in these columns, the commission, before which the question of all new rates has to be presented, while by no means permitting the exorbitant increase in rates as requested by the railroads, did admit of a compulsory classification of ores under 25 pesos valuation, those between 25 and 50 pesos, and those over 50 pesos, and an increase in the rates of 10, 20, and 30% in these three classes of ore. Not satisfied with this, however, the railroads have made an appeal to Leonardo Fernandez, Secretary of Communication, asking that they be allowed, if not their original schedule, at least a material increase over that admitted by the commission. However, under present conditions, it is not believed by many that the railroads will get their demands.

The stopping of purchases of custom ores by the Tezuitlan Copper Co. for its smelting plant promise to be a serious blow to the mines in the various districts of Oaxaca, but an arrangement was affected between the Consolidated Metals Co., which has many contracts for ore throughout Oaxaca, and Seckbach & Co., ore-buyers of Mexico City, whereby the ores of such properties as wish to produce under the present markets are taken care of. But many have suspended in Oaxaca, and the Taviche district is quiet, although the Conejo Blanco continues its shipments of high-grade gold ore. Others are still shipping to the smelter of the Magdalena Smelting & Mining Co., this being the name of the new company organized by Mr. Hamer in New York last fall, with a capital of $5,000.000, and which will absorb the smelter and mines of Messrs. Hamer and Williams, though both retain large interests in the new company. Henry W. Catlin, of New York, president of the new organization, has been on a recent trip of inspection, and is quoted as saying that a large part of the new capital will be put into many necessary improvements at the smelter and in opening the mines, particularly the San Carlos and Providencia, in both of which the increasing supply of ore has been most encouraging. The Tehuantepec Silver Mines Co. of Boston, which recently purchased the San Francisco mine in Taviche, has now acquired also the adjoining properties, consisting of Rey de Plata, Carmen, San Albino, and Amplicacion de Las Animas from the American Consolidated Mining & Smelting Co., controlled by A. W. Cunningham and associates of Waco, Texas. The properties are at present twelve miles from the railroad, but only one mile from the new road, and under proper management will undoubtedly become one of the large mining enterprises in Mexico. And further encouragement is given to this and to the Oaxaca district, by reason of the concession obtained by S. P. Applewhite for the installation of an electric power-plant to be operated by the waters of the Rio Grande. The presence of R. L. Stevens and W. Harvey Weed in Mexico City on the way to Chilpancingo and the Balsas River district in the State of Guerrero has given rise to the rumor that the Tennessee Copper Co. is going to buy and build in that vicinity.

Chihuahua is quite jubilant over the results of the drillings for oil that have been carried on by W. R. Hearst and James Keene, at the instance of C. R. Troxel, and which have resulted in striking oil in one hole at a depth of 1400 ft., in another at 400 ft., and a third hole has just been started. The holes are in the eastern part of Chihuahua, near Ojinaga or Presidio del Norte, and along the line of the Kansas City, Mexico & Orient railroad. The first hole is only about six miles from the Rio Grande, and the work is proceeding south in a more or less direct line with about six miles between the holes. The original concession was for 5000 acres, but now these pioneers are after 200,000 acres additional. An analysis of the oil from the second well is said to have given:

	%
Naptha and light oil	14.38
Light kerosene, 150° F.P.	31.05
Heavy " 128° F.P.	22.60
Lubricating	20.00
Paraffin	10.22
Total	98.25

This is an oil much to be preferred for general use over those of the San Luis Potosi and Vera Cruz fields, which have an asphalt base. The endeavor was to keep matters as quiet as possible, but results leaked out, and it is said that E. L. Doheny of the Mexican Petroleum Co. (S. L. P. & V. C.), and others are scouring the new fields. And as this chances also to be near large zinc deposits the visionary ones already see a replica of the Kansas fields with the oil burning, gas flaming, and stand after stand of zinc smelters. Premature as this may be at this time it seems certain that there is money here in Mexico for the man who will go into zinc smelting, in the region mentioned above if the oil proves up, or near the coal and zinc fields in the vicinity of Monterrey. The call for zinc in Mexico is becoming greater and greater every year, and there is money for the man that will smelt the ore here, and follow up his product by putting it into marketable shape.

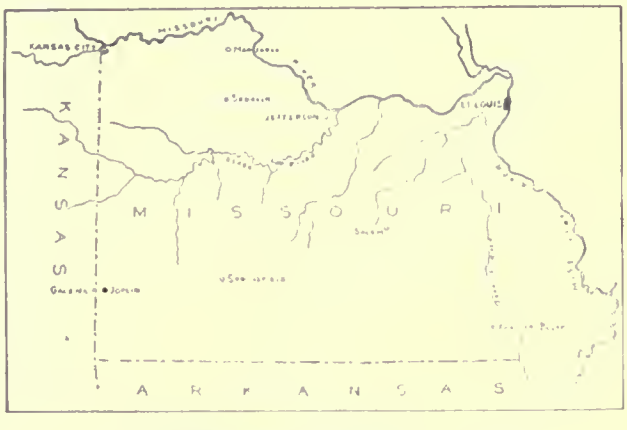
The Blaisdell Coscotitlan Syndicate, for which H. A. Barker is general manager, has acquired a large area of ground three miles southeast from Pachuca. The tract is flat, and lies on both sides of the Pachuca river, whose banks are low, permitting its flow at times to spread over the entire plain. This area has received the tailing from the old mills of Pachuca, as well as the wash from the mineral-bearing hills of the district, and is covered by a deposit of silt and sand to an average depth of 2½ ft. Such deposits include the accumulations of mill-tailing of a century or longer, but the bulk of it resulted from operations during the last 40 years. Mr. Barker estimates that there are 2,000,000 tons of material that may be successfully cyanided for the gold and silver it contains. Much of this tailing resulted from the *patio* process, and is in a finely divided state. It is estimated that it will average between P7 and P8 per ton, being 75% silver, and 25% gold. The silver is a sulphide and the gold is associated with it. The material also contains considerable iron. With this kind of a proposition the company began last fall to erect a plant for digging, conveying, re-grinding, and cyaniding the material. The work began Oct. 7, 1907, and on Dec. 27 there were 20 steel-vats, miles of pipe-line, chutes, conveyors, and other equipment in readiness. The plan is to begin operating by Feb. 15, 1908. The material will be taken up and placed in tram-cars with side dump, which will discharge into a chute, within which a Blaisdell conveyor operates. By this means the material will be elevated 30 ft. and dumped into pulping vats. Callow screens will be used to take out the vegetable matter. The mixed pulp is to be classified by spitzkasten, the coarse sand being discarded for future treatment. The slime will be re-ground in Krupp tube-mills, reducing it to sizes ranging from 80 to 150 mesh. The tube-mills are lined with the El Oro lining. The pulp will then be further subjected to cyanidation in agitating vats. A 5-ton plant will be erected to test the Adair-Usher method of slime-leaching, in which the material is held in suspension while the cyanide solution is passed through it. It is a method used on the Rand. The 20 steel-vats are each 36 ft. diam. and 11 ft. deep, except three sand-filtering vats, which are but 8 ft. deep. The pumps, conveyors, tube-mills, and other machinery will be operated by electric power. The final clarification of the solution will take place in a Blaisdell filter, after which the solution will pass to the zinc-boxes for precipitating the metals. They are putting in ten zinc-boxes, each 17 ft. long, 4 ft. wide, and 2 ft. deep. The precipitate will be melted in steel crucibles. Designs are made for a refinery for separating the gold and silver. The plant will have the capacity of 500 tons per 24 hours.

The Tiro General mine at Charcas, San Luis Potosi, is well developed, and is shipping 4000 tons of ore per month to the smelter at Aguascalientes. These shipments carry 2½% copper, as a mixture of sulphides and oxides. In the mine are separate bodies of galena, zinc-blende, chalcopyrite, and iron in a silicious and lime gangue, which are to be concentrated in a plant just installed under the advice of R. C. Canby, of El Paso. It is equipped with crusher, four sizes of rolls, sizing screens, and Sutton & Steele tables for dry concentration. There is a separator for collecting the fine dust before the bulk of the pulverized material passes to the screens, the latter making five sizes. Each sized product is concentrated on a separate table, which is said to have a capacity of 40 metric tons per day. It is also proposed to employ a di-electric separator for separating the copper from the zinc after these have been parted from the lead and iron. J. G. Creveliug is general manager of the property.

JOPLIN, MISSOURI.

Resumption of Work on Better Prices for Lead and Zinc.—Output of Various Mines.——Successful Prospecting at Webb City.——The Oronogo District.—Work at Aurora.—A New District in Oklahoma.

The re-opening of practically all the mines of Joplin camp and 40% of those at Webb City, following the increase in the prices of both lead and zinc ore, is the leading feature of the past fortnight. The price of zinc concentrate running 60% zinc, advanced to $40 per ton, while lead concentrate running 80% brought as high as $45 per ton. This price makes possible a profitable operation of all the



Sketch Map Showing Position of Joplin.

mines working orebodies running as high as 5%. The weekly production of the district is still below 3500 tons of zinc and 600 tons of lead, when normally it is above 5500 tons and 1200 tons. The plants that have resumed operation should increase the zinc output at least 600 tons. A majority of the operators in the sheet-ore belts will not re-open their plants until zinc reaches a base of $45 per ton. Until then Webb City and Prosperity, from which comes the major portion of the tonnage of both lead and zinc, will not produce. The Underwriters Land Co., handling 1000 tons daily, has not been able to agree with the workmen as to a lower wage scale, and the plant remains idle. The American Zinc, Lead & Smelt-

ing Co., which has six plants in the Prosperity-Porto Rico camp and having an aggregate daily tonnage of 3200 tons, has not resumed work. At all the mines resuming work lower wages are paid, the decrease ranging from 15 to 25% as compared to before the panic.

During the enforced shut-down most of the large operators have undertaken a complete overhauling of their plants and they are making repairs looking to an increased tonnage when the mills resume work. The old companies have done much dead work in their drifts, while others are prospecting new tracts. The most important development in the Webb City district is the completion of the prospecting campaign of the Glass Mining Co. on its 160-acre tract in the north sheet-ore field. The company put down 30 drill-holes, all of which penetrated ore from 180 to 225 ft. The orebodies were in a few instances 24 ft. thick. A double-compartment shaft has been sunk and cross-cuts driven, so as to prove the records of the drill. A 400-ton mill has been erected. A second shaft has been started to intercept one of the drifts in order to provide ventilation and a sufficient hoisting capacity to keep the mill in steady operation. The Indiana Mining Co., a sub-lessee, has sunk a shaft and opened the same run of ore and is now erecting a concentrating plant. These developments add 160 acres to the proved sheet-ore belt of the north Webb City field. ——At Oronogo, the Old Judge Mining Co., at one time a heavy producer from the upper levels, has opened a new body of sheet ore at 180 ft. The ore runs 8% zinc concentrate. A drift 90 ft. from the shaft has revealed a uniform orebody. A second shaft is being sunk and a 250-ton milling plant is now completed. The discovery will revive many of the abandoned mines that were supposed to be barren below the old levels.——The Mercantile Mining Co. completed its new concentrating plant at its No. 1 shaft. The plant is an innovation in mill structure, being of steel throughout, with a steel storage bin of 500 tons capacity. The mill is covered with galvanized sheets and all the floors in the building are concrete save that of the jig-room. This, together with the jigs, is the only wood found in the entire mill. The plant will handle 250 tons per 10-hour shift and is constructed to handle sheet ore yielding from 3 to 4% concentrate. The power plant consists of two Snow gas engines of 200 hp. each, one driving the mill and the other the 12-drill air-compressor. This is the only completely fireproof plant ever constructed in this district, though the utilization of galvanized sheets as a mill-covering has become a settled practice.——Adjoining the Mercantile lease the Carbondale Mining Co. has just completed a 250-ton plant to handle the same character of ore. A feature of this company's plant is the installation of hoisting cages in its double-compartment shaft. The cages and hoisting arrangements follow the plan of those used in the coal-fields of Kansas. This feature is found at only one other plant in this district.——The Tri-City Mining Co., at Carthage, has undertaken the development of a new tract of land northwest of that city and the results have been gratifying. The drilling done on 80 acres of the tract has developed two runs of the ore, one at the western extremity and one on the east forty. The first showed ore at 240 ft. and continued to 258 ft. The ore discovered was a mixture of galena and zinc-blende, the latter predominating. On the east 40 acres ore was found at 228 ft. and showed a 16-ft. face of disseminated ore in a chert matrix. A shaft is being sunk on this land and a concentrating plant will be erected.

At Aurora, Scott & Coleman have just completed prospecting a new tract of land east of the limits of the old camp and discovered a new orebody at a lower level than had been previously demonstrated. Ore was encountered at 268 ft. and a deposit 30 ft. thick was penetrated. A shaft has shown the drill records to be correct. Drifts have been pushed east and south of the shaft; while the underground work is progressing, a concentrating plant is being erected. On this 80-acre tract 27 drill-holes have been put down. Drilling is being continued to determine whether the new discovery is an extension of the orebody in the Sand Ridge mine on the north. The discovery was made on the south end of the new tract.——The Sand Ridge mine, employing 150 men and working at the 300-ft. level, has been re-opened. Operations were discontinued two years ago, when a disastrous cave flooded the mine. The cave occurred beneath the bed of a stream flowing across the property and for some time all hope of re-opening the mine was abandoned. The company was re-organized and built a flume 1600 ft. long to carry the stream over and around the caved ground. The feat was successful, and after two months steady pumping the water was lowered to the working levels when work was resumed in one of the most productive mines ever opened in Aurora. Heavy timbering had to be done in the lower levels to secure the drifts under the caved ground.

At Miami, in Oklahoma, prospecting has demonstrated an entirely new district, extending over several square miles. The ore is found in a sheet-ground formation at shallow depths as compared to Joplin and Webb City. Ore is found at 80 to 150 ft. The Emma Gordon Mining Co. has drilled 78 holes; a majority of these showed ore from 18 to 30 ft. thick. This company is sinking four shafts; one shaft is in ore, and at this point a 400-ton mill is nearing completion. Two other 400-ton plants will be erected at once to treat the output from the other shafts.——Amos Hatton of Webb City is developing a 200-acre tract. Five drill-rigs are at work demonstrating the limits of a sheet-ore body recently discovered. Four shafts are being sunk and a 350-ton concentrating plant will be finished in a fortnight. ——The Jennie May Mining Co. operating a 10-acre lease north of the city has opened a rich deposit of zinc. A concentrating plant will be erected.—— The following mining companies have drilled their leases and are now sinking shafts in this new camp: Lucky Strike Mining Co., Index Mining Co., King Jack Mining Co., Joplin-Miami Mining Co., and D. D. Isley.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

For the compressed-air supply for rock-drills, steam-turbines have begun to compete with reciprocating engines as motive power.

Hot blast has been abandoned at the smelter at the Copper Queen mine, Arizona, at Ducktown, Tennessee, and at Mt. Lyell, Tasmania.

Aluminum, sodium amalgam, and electricity have been tried in place of zinc shavings as precipitants for gold in cyanide solutions, but they are not practical.

The water issuing from the mines at Butte, Mont., is acid: pump parts exposed to it are made of phosphor-bronze and all columns must be lined with either wood or lead.

Drills sharpened by machinery are more perfect than those sharpened by hand and the saving in labor alone is estimated as amounting to at least 65%: this will in a short time pay for the machine.

Pyritic smelting, in which the sulphur in the ore is utilized as fuel in the blast-furnace, is increasing in use for the treatment of ores containing precious metals but poor in copper; this is especially true in districts where fuel is expensive.

In lead smelting there has been a tendency in recent years to revert to older methods; the reinforced dust chambers have fallen into disfavor, and the lime-roasting process does not appear to have been an unqualified success.

Ore on the dump in Arizona is personal property and not real estate, according to a recent decision by Judge Campbell in the District Court at Tucson, Ariz. Ore mined from the mineral claim of one party and dumped upon the mineral claim of another party therefore belongs to the party owning the claim from which the ore was mined.

The average cost of drilling 35 holes to a depth of 200 ft. through sand, clay, shale, soapstone, and sandstone with a hollow-rod drill was 18c. per foot. This included all labor, repairs on machinery and tools and a reasonable allowance for depreciation of equipment. The cost of drilling through jasper, marble, granite, chert, or very hard material will often average $3 per foot.

The amount of new gold coins issued by the Royal Mint during 1907 was £20,951,000, of which £18,800,000 was in sovereigns and £2,087,000 in half-sovereigns. The amount of gold coin withdrawn from circulation was £2,700,000. The new silver coins issued numbered 37,343,000, having a face value of £2,019,789; and 68,570,000 new bronze coins were issued, of the value of £227,550. All these figures show a considerable increase over those of 1906.

Calcined magnesite varies in price according to the amount of roasting given it; that resulting from the manufacture of carbonic acid gas brings a lower price than that specially calcined and given a longer roast at a higher temperature. The calcined magnesite at present sold in San Francisco brings $14 per ton. The crude magnesite costs in the San Joaquin Valley about $3 per ton and the freight to San Francisco is about $3 per ton. The roasting is done at Porterville. The calcined material is mainly used as a digester for wood-pulp in paper manufacture.

Electric power for hoisting and haulage can be utilized to great advantage in the slate-quarrying industry. In Wales, for every ton of slate obtained from 20 to 30 tons of dirt, broken stone, and other débris must be handled. From the North Wales power-house a 10,000-volt current is carried about 50 miles to the Darbishire, Dinorwic, and Oakley slate-quarries, where it is lowered to the proper working-pressure for light and power service. A total of about 5000 hp. is installed in electric motors. The saving in cost as against the use of coal has been considerable.

The method of sinking shafts through water-bearing strata of sand or silt by sinking continuous cylinders and excavating the ground from inside them has reached its greatest development in Germany. A cylinder, usually of masonry built upon a massive iron cutting-shoe, is sunk until skin-friction prevents its further descent. Tie-bolts attached to the cutting-shoe are built into the brickwork and by means of these a heavy iron anchor-ring is secured to the upper part of the shaft. A cylinder of iron is then built up beside the first cylinder; it is forced down by powerful hydraulic presses which work against the anchor-ring. Modern practice seems generally to favor the use of some form of dredge for excavating the material from the inside of the cylinder.

The amount of water which can be decomposed in a given time by an electric current is directly proportional to the strength of that current, therefore, the amount of water that can be decomposed by 1 hp. hr. is dependent upon the current-strength used. At 100 volts 1 hp. hr. equals 7.46 amperes flowing continuously for one hour, during which time it would decompose 0.28 gram of water. The amount of water that can be decomposed by any number of watt-hours in a given time may be determined by multiplying the watt-hours by 0.0373824 and dividing by the voltage. The result will be the weight (in grams) of the water decomposed. The most suitable electro-motive force is dependent upon the size of receptacle retaining the water, also the size of plates used, and their distance apart. Ordinarily for electro-chemical processes, from 5 to 10 volts is found most suitable.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Cyanidation of Ore Containing Both Coarse and Fine Gold.

The Editor:

Sir—Under 'Discussion' in the issue of December 21, Mr. E. M. Hamilton suggests re-grinding, with the idea that the gold would be either disintegrated or flattened into very thin plates. Undoubtedly there is a difference in the physical condition of gold occurring in different places, and it is possible that all gold might not yield readily to this treatment. This idea is suggested by an experience at Cooke City, Montana, where in one part of the mine we found free gold that failed to dissolve after four days exposure to an 0.25% cyanide solution. The ore was crushed dry by rolls through 20 mesh, but an examination of the tailing showed that all of this gold would pass 60 mesh, and nearly all would go through 100 mesh. After the sudden rise in the value of the tailing due to the unexpected appearance of this free gold in a mine which had rarely shown a color, amalgamated plates were introduced into the sluice-boxes through which the tailing was discharged. Practically none of the gold was saved, and then different types of riffles, with quicksilver, were tried and proved unsatisfactory. Following this, blanket tables were used, a concentrate running up toward $1000 per ton was obtained, and the tailing dropped back to an approximately reasonable figure. Possibly if this gold could have been put through a tube-mill and ground to 250 mesh it would have dissolved satisfactorily, but with our conditions, though it passed the finest screen we had, it would not dissolve.

GEO. A. PACKARD.

Boston, January 15.

The Editor:

Sir—If further discussion of your question regarding the treatment of ore containing coarse gold is in order, I would like to offer the following suggestions:

I infer from Viator's communication that the crushing must be done in cyanide solution, otherwise amalgamation followed by cyanidation would be the natural course. Even when using cyanide in the batteries I believe the same plan is the best for the purpose, provided the solvent action of the cyanide on the plates can be avoided. This I think can be done in a simple way by making the plate the negative electrode of a galvanic couple, for it is well known that the cathode is not attacked by the electrolyte while the current is flowing. By making use of this fact we ought to be able to protect the plates from all action of the cyanide, and perhaps make them a little more active as amalgamators. The couple ZnCuHg (amalgamated plate) gives a potential difference of 0.35 volt in a 0.1% cyanide solution, the current going in the solution in the direction indicated by the arrow, thus making the plate the negative element, or cathode.

Should any one care to try the experiment I would suggest placing a few narrow strips of zinc along the edge of the plate, and insulated from it by a thin strip of insulating material. The strip of zinc and the insulator might be fastened to the plate with a couple of copper rivets, which would serve to short-circuit the couple and make the amalgamated plate the cathode, and thus protect it from the solvent action of the cyanide. The solution carrying the pulp over the plate would be the electrolyte, and the current would go from the zinc through the solution to the plate and back through the rivets, thus completing the circuit. The zinc should be bright and clean, as cyanide seems to have but little action upon ordinary rolled zinc.

I believe a few such couples around the plate would be sufficient to protect it from the action of the cyanide, and the amount of zinc going into solution from the anode would be so small as to be of no importance.

Should this method not give sufficient protection, another plan would be to use a carbon anode placed in some convenient position and just touching the pulp, and then pass a very weak current from it through the pulp to the plate and then back to the generator. Probably one ampere, or even less, of current would be sufficient for the purpose. By protecting the plate in this way any desired strength of cyanide could be used, which might prove particularly advantageous in the case of silver ores when a strong solution is necessary.

JAS. S. C. WELLS.

New York, January 18.

Labor Conditions in the Coeur d'Alene.

The Editor:

Sir—You would do a justice to this district if you would kindly publish the following in answer to 'A Word for the Miner' in your issue of December 21.

On page 774 I find the following statement: "The average employee of a mining company can either accept the treatment offered him, or get out. He has no appeal, no chance to be heard; if he takes exception to some arbitrary rule of the management, he gets his time. If he moves to a new camp he meets the same conditions." From this statement one would think that the above was an unusual condition and applied solely to the mining business, yet as a matter of fact the same condition is found in any and all industries. The farmer tells the farm laborer when to sow the wheat; the captain tells the sailor when to scrub the deck; the railroad rules and regulations tell the engineer the time and conditions under which he is to run his train; and the army regulations prescribe the rule of drill for the soldiers. If such were not the conditions throughout the world it would be impossible successfully to carry on any great industry or enterprise. If each laborer on the Panama Canal were given an opportunity to dictate the policy that was to be pursued for one day we would certainly reduce that great work to chaos.

In reference to the employment office, there was one established at Wardner, and another at Wallace, shortly after the blowing up of the Bunker Hill mill in April, 1899. The original purpose of these offices was to prevent the employment of union men, but the system has worked so well and given such satisfaction that these offices have been continued up to the present time. Under the old system of the miner applying to the foreman of the mine for employment, the foreman was annoyed and interfered with at all times by men applying for work; and in the more accessible mines of the district such a foreman could do little but answer the men making application, so that very little of his time was devoted to his real duties of directing the work in the mine. Again, some excellent foremen would soon surround themselves with their personal friends; these they would later allow to take advantage of them to the detriment of the company, and the efficiency of the miner would soon reach such a low point that it would become necessary to discharge the mine foreman and his entire crew of followers. The employment bureau removes all these difficulties by having central offices in the towns of the district where they are accessible to the men seeking employment, and are directly connected by telephone with the mine foreman. Today we find in all large well-managed industrial works that there is a man in the office specially employed to hire men, and the foreman's attention is devoted to the overseeing of the labor, and such will soon be the conditions at the mines.

With reference to Jack Bayne, he is one of the most honorable, honest, and kind-hearted men that I have ever met, and I have known him to send men who were discharged from one mine to some other mine until they had been finally discharged from every mine in the district. He was formerly a mine foreman in this district, and it is true that he has not received the diplomatic training, nor has he acquired the polished manner of our genial Secretary of War, William Taft, yet he has always treated any man seeking employment most justly.

Some of the mines of the district are so situated that they were compelled to erect boarding-houses for the accommodation of their employees, others have never had a boarding-house, and a few, known as the Federal properties, have both stores and boarding-houses that are commonly reported to be owned by the officials of this company. I have eaten in numerous boarding-houses in the mining districts of the West, from Mexico to British Columbia inclusive, and I can honestly say that the boarding-houses of this district average better than those of any district in which I have ever been. The Standard boarding-house is a well built frame building, equipped in the most modern manner, electric-lighted and steam-heated throughout, divided off into rooms, most of which contain two single beds, and if it so happens that one bed is occupied by a man working on day-shift and the other at night, it certainly becomes necessary to call the man working on morning shift. Unfortunately, mines are not always found in the most desirable places, but I fail to see how the management is to blame for this fact, or how the working man could change it, and in the development of the Standard it was necessary to run an adit from a narrow canyon less than 300 ft. wide; in the centre of this canyon we find a mountain stream, and on each bank a railroad, so that under these conditions the only available place to construct the boarding-house and other necessary buildings was between the two railroads; yet even as it is, as far as smoke and dirt is concerned, the conditions are much more favorable than in the centre of the business district of the City of Pittsburg; and we cannot expect to obtain industrial activity in any portion of the world without some of its inconveniences. One dollar per month is deducted from each employee in this district for hospital dues, this amount being paid directly to such hospital as the miner desires to patronize. The section in reference to the insurance is a misrepresentation of the facts; a system of insurance was introduced here some two years ago, and a complete set of rules governs and regulates this system, however, the final governing board consists of four members, two chosen by the mine-owners, and two by the men, and this board has the final power to do that which it thinks is just and equitable.

The following is a general outline of this system: Each miner is charged $1 per month for insurance, provided he works ten or more days in a month; if he works less than the above number of days he is charged ten cents per day; to the sum so collected the company adds one-half of such amount, and in case of accident causing partial disability the miner receives various sums not in excess of $1500. In case of death the family of the miner receives $1500, or those directly depending upon him may (at the option of the board of directors) receive the same amount; in case of death without any family, or anyone directly depending upon him, the funeral expenses are paid by the insurance association. This system has worked well and there are only two improvements that I would suggest to make it nearly perfect: First, the company to contribute the same amount as the workman; second, each region to be divided by law into mining divisions as at present for locating mining claims, and each such division to be compelled to maintain one insurance company to which all the mines in the district shall contribute, so that the men employed in a small mine will receive the benefit of such insurance, the same as the employees of the larger mines now.

In reference to the heat in the summer time, I do not just see how that could be changed by consulting with the miner, and as a matter of fact the conditions here in the summer are the most favorable of any mining camp in the entire United States; during the past year we had only a week of what might be termed summer weather, and during that week the thermometer did not register as high as 90° in the shade during the hottest portion of the day. As for flies, a man working in a mine has little conception of what real flies are, and if he will take a trip to a farm house, a surveyor's camp, or a railroad construction camp, he will come back to the mines

pleased to know that he is engaged in an occupation where he is not annoyed by 'real flies.'

As for pneumonia, we must admit that any man working in a warm place, where the ventilation is poor, is liable to this disease on being suddenly exposed to the cold air for an extended period of time, but the avoiding of this disease is entirely within the hands of the miner, and if he will take ordinary precautions to protect himself he will not be troubled with pneumonia. A most frequent cause of his contracting this disease is the habit of spending the evenings in a poorly ventilated saloon, playing cards, and drinking alcoholic liquors until a late hour, when the miner goes home to his damp cool cabin in a partially intoxicated condition and by morning he is chilled through and the blood has congested in his lungs.

The Coeur d'Alene foundry was conducted here for more than ten years by parties that were not directly interested in any of the large mines, and a few years ago one of the partners, a Canadian by birth, died, leaving his estate to his relatives in Canada; after various negotiations the operators in control here, with one exception (and this for personal reasons), took over this interest and advanced the money necessary to equip the plant, and any man that has ever conducted any mining enterprise will appreciate the great advantage that the mine-owners now possess in having a properly constructed and conducted works of that nature in which, at a moment's notice, they can have repairs made, or any parts of machinery duplicated, and by possessing this interest in the works they have placed themselves in a position where they can adjust and regulate prices on an equitable basis.

With reference to the struggle of the owners of the Hercules with the Federal company, this is mostly a matter of imagination, and the relations of the two companies have been much more pleasant than the relations of the Bunker Hill company and the Federal company, but the fact that the Hercules has always been a union mine has greatly magnified the true facts in the minds of all the union element. The statement that the Bunker Hill & Sullivan mill was blown up on account of a cut in the already low wages paid the men, is not correct. The mill was blown up in April, 1899, and the rate of wages paid at that time was the same as had been paid for the seven years previous, namely: Shaft and timber-men, $4; miners, $3.50; car-men and shovelers, $3 per day. The blowing up of the Bunker Hill mill was the most foolish act ever perpetrated by any body of working men, and it was one of the greatest injuries to the cause of Union labor that has ever occurred in the West. At the time of the blowing up of that mill every mine in the district was a Union mine with the exception of the Bunker Hill, and more than one-third of all the men in that mine were members of the Union. The Union sent an ultimatum to the Bunker Hill to discharge all non-union men and make the Bunker Hill a Union mine; and the refusal of the Bunker Hill to do so was the sole and only reason the Union men had for the destruction of the property, and by the destruction of that mill the Union lost all the prestige that they had obtained during the seven years previous, and they have not been able to regain it during the seven years since then.

In conclusion, I may add that I am not in the employ of any mining company in this district, and am not a mine owner in the district, and it is not a personal matter with me in any way. My only desire is to correct errors and furnish unbiased facts.

J. P. K.

Wallace, December 24.

College Instructors.

The Editor:

Sir—I have read Mr. John A. Reid's most interesting letter; but he seems to me to miss the one thing we lack in all our colleges, and that is the magnetic professor who creates enthusiasm. I have crept in to many a college class-room, and listened to well-prepared and thought-out lectures; but never once, in this broad land, have I been thrilled as I have been in the colleges of Europe. Why? Because the lecturer was always weighed down by the spirit of commercialism; I mean, he seemed always to be striving to give instruction that would pay to know; and this is certainly not the right spirit for colleges, nor will it produce really great men.

I remember when a student at Freiberg, how Bernhard von Cotta inspired me to make petrology a life study how his talks, both in the lecture-room and in the field, thrilled me, and they have not only given me a great joy in life, but have put lots of money into my pocket as well. Man is a warm-blooded animal, and if his blood be cooled by cold-nosed commercialism, he will never do good work or inspire the young. My private tutor in Freiberg was Theodore Richter, the discoverer of indium, and he taught me metallurgy, spectroscopy, and blow-pipe analysis, for 25 cents (ye gods!) a lesson, nominally of one hour, but usually two to three hours; and he would never take more than 25 cents; so when I left, I gave him a box of cigars (all he would accept), and as he embraced me, tears stood in his eyes. We never met again, but the enthusiastic 'send off' those two great men gave me, has been worth 'millions' to me, in my life-work. I owe an untold debt of gratitude to the enthusiastic teaching of Faraday, Williamson, St. Claire Deville, and Hofmann in chemistry; Miller in mineralogy; Bonney, Morris, and von Studer in geology; Huxley in zoology; Tyndall, Maxwell, and Thompson in physics; Percy, Gruner, and Siemens in metallurgy; and many more. Now why is it we do not have lots of men of that stamp here? Our youth is eager and impressionable, and the field is ripe for the harvest. Why do our best painters live and do their best work abroad? It is because our social atmosphere is unkind to them. And so it is, and more so, to men of science.

We are living here now in an age of 'brass' or 'iron'; and history does not record the names of any great teachers in the 'stone,' 'bronze,' or 'iron' age: it may be an 'age of gold,' but certainly not a 'golden age.' When a learned man ranks at least with a millionaire, there may be some hope for us.

After a while this will pass away, and a leisured—not a lazy—class will arise, and all will be well.

The college is emphatically a place of learning, of grand thoughts, and noble aspirations, and never must be dragged down by the spirit of commercialism. Practical instruction is very necessary, and we had it to the fill at Freiberg; at the same time, we had men there who could and did, add a higher plane of thought to their lessons. There are many well-known men in this country who are contemporaries of mine there, and I feel sure they will bear me out in my statements. I would not have missed my college education at Cambridge, Paris, and Freiberg for 'millions'; it has given me a joy in life and in my work that no money alone can ever buy; and to the question, did it pay? I answer: A thousand times Yes; not only in dollars, but also in a joyous life; and the longer I live, the more I feel I owe to those great teachers who started me right on my life's journey.

WALTER E. KOCH.

El Paso, January 21.

Green Gold.

The Editor:

Sir—The communication of Mr. T. K. Rose, the eminent chemist of the Royal Mint, London, which appeared in your issue of November 23, in relation to the report in the matter of certain experiments made by me in determining the cause of some gold having a decided green color, attracted my attention at the time of publication, but pressure upon my time precluded reply before this.

It was my impression, at the time we made the experiments last year, that we did not pickle the samples of alloy, but the reasoning of Mr. Rose being so logical, and feeling my memory might be at fault and that it was possible "that a cast and rolled alloy never shows a green color unless it is subjected to some pickling process which somehow converts part of the gold near the surface into the well-known violet or purple condition," I concluded to repeat the experiments I had previously made. Therefore I had 11 samples of fine gold and silver made up, beginning with 990 parts gold and 10 parts silver, and reducing the gold in each subsequent sample 10 parts and increasing the silver in a corresponding quantity. Each sample was numbered, and upon being flattened out after cooling, without pickling or other treatment, showed the following results as to the color:

No. 1	990	yellow
2	980	lighter
3	970	lighter
4	960	lighter
5	950	slight shade of green
6	940	increased shade of green
7	930	increased shade of green
8	920	increased shade of green
9	910	increased shade of green
10	900	decided green
11	850	full green

Thus it would appear that the presence of the silver in variable quantities is responsible for the change of color of the gold from a deep yellow to a decided green; and in all probability if the number of samples of alloy had been increased by the addition of the same amount of silver to each until the quantity of that metal should predominate, we would find the color shading off from green into a white.

FRANK A. LEACH.

Washington, January 25.

A Suggestion.

The Editor:

Sir—In your issue of January 18 is a suggestion by a 'Musher,' also an editorial on the same. This suggestion sounds natural and probably expresses the opinion of prospectors generally. Of all the departments of mining, the prospector is the only person who buncoes himself, and so often that it seems as though he took delight in it.

It has been the experience of the writer to have seldom met prospectors who knew where to look for a mine and where not to look for one, that their own descriptions of their 'bonanzas' have often been the cause of long and exposed trips to see nothing in the way of a mine. They always get picked samples for assay and their veins usually "widen as they go down." The geologic conditions that surround a body of ore, among which metamorphism, brecciation, and surface oxidation are usually apparent at the surface, are irrelevant to them.

It appears that the 'Musher' has things reversed. If any appropriations were to be made for advancing mining interests in new fields, the better expedient would be to take them to the United States Geological Survey, and have that department examine and report on them, which would be a source of reliable information, in contrast to the incoherent reports of prospectors.

W. P. R.

Seattle, Washington, January 25.

[Our correspondent is rough on the prospector, and puts us in an awkward position, for if we do not publish what he says, he can charge us with conducting a prejudiced paper, while by publishing his phillipic we place ourselves in danger of our lives. We hope any prospector that feels really badly about it, will give us the pleasure of a call, for, in the phrase of the camp, "the cigars are on us."—Editor.]

A Correction.

The Editor:

Sir—Kindly allow me to slightly correct your very complimentary editorial note of February 1, as I am somewhat sensitive in the matter of priority of inventions. It was Mr. Oliver who "hit upon a new idea." My part was to sit in judgment on his enthusiasm or comfort his despair.

ARTHUR DE WINT FOOTE.

Grass Valley, February 3.

ZINC DEPOSITS have been developed in Orange, Shasta, Mariposa, and San Bernardino counties, California. In 1906 shipments of concentrate carrying sphalerite and pyrite were made by the Western Zinc Co. from its Silverado mine in Orange county to San Francisco, where it was used for the manufacture of chemicals. At the Afterthought mine in Shasta county, the zinc-bearing copper sulphide ores were treated experimentally for making zinc oxide.

SMELTING IN GLOBE IN 1893.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

During the years 1892 to 1894, N. S. Berray was superintendent of the Old Dominion Copper Co., at Globe, Arizona, producing blister copper from the oxidized ore of this property. Costs of labor and supplies were high, common labor being $3.25 per day, wood $7 per cord, and coke, after allowing for losses *en route*, $42.50 per ton. Naturally, with freighting so high, only the best coke was obtained, and the copper was put into its most concentrated form as blister.

The mine ore was as follows:

TABLE I. ORE ANALYSES.

	SiO_2	FeO	CaO	Cu
Surface tunnel stope (average)	34.6	26.8	2.0	15.8
Second level, main stope	32.0	34.0	2.1	11.6
Second level, northeast stope	25.4	34.4	3.7	14.1
Fifth level, richest quartz ore	49.4	19.7	1.1	19.8
Fifth level, black ore	31.1	32.1	3.2	13.1
Seventh level, richest quartz ore	39.2	25.4	1.1	21.2
Average	35.3	28.7	2.2	15.9

The last two ores contained 0.006 and 0.003% arsenic respectively, with traces of bismuth and antimony.

There were three furnaces, two being constantly in operation. These furnaces were of the round-cupola type, 36 in. diam. at the tuyeres. A new kind of wind-box on No. 2 furnace increased the temperature of the blast by 60° F; No. 2 ran faster than No. 1 and 3, with a maximum output of 80 tons daily. The increase over the other two furnaces was 10%. The works were not operated on Sundays, and the slag on Monday morning appears to have been higher in consequence.

Taking the performance for the second half of 1893, in 268 furnace days there were put through 15,510 tons of ore with a consumption of 2663 tons of coke, using 3570 tons of limestone, and producing 4,033,135 lb. blister copper, which contained 3,871,807 lb. fine copper. Counting 1039 tons of slag returned to the furnace, we have a total of 20,119 tons put through. The coke was 13.2% of the charge, the limestone 17.7 to 22.9%, figured on the ore put through. The ore, containing 14.2% copper, yielded 12.4% blister copper, while 1.93% went into the slag. There was thus a loss of 12.6% in smelting. Figured by the slag, which constitutes 83% of the ore put through, the loss should be 11.2% of the copper, the difference, as compared with the former figure, being presumably due to loss by volatilization and by flue-dust. The ore put through was 58 tons and the charge (including slag) was 75 tons per furnace-day. In this period of six months only 3.3 tons of custom ore was put through, yielding 2162 lb. copper. For steam-making there was used 633 cords of wood, or 2.2 cords per furnace-day.

The coke used was either Pocahontas (West Virginia) or Connelsville, each kind hand-picked. Analysis showed:

Coke	H_2O	S	C	Ash
Connelsville	1.16	0.99	90.31	7.04
Pocahontas	0.70	0.70	92.80	6.57

The copper bullion, or blister copper, carried but 3 oz. silver per ton and no gold. The table herewith gives some analyses:

TABLE II. OLD DOMINION COPPER BULLION IN 1893.

	March	July.	August.	September.	October.
Fe	0.12	0.72	0.74	0.80	0.97
Cu	98.91	98.27	98.30	98.24	97.52
S	0.64	0.60	0.55	0.53	0.69
As	0.057	0.039	0.040	0.54	0.052
Bi	0.010	trace	0.007	0.006	trace
Sb	0.008	0.019	0.014	0.021	0.014
Slag	0.065	0.060	0.120	0.007	0.180
	99.810	99.718	99.771	99.658	99.426

For the latter half of 1893 the mine expense is thus given:

TABLE III. MINE EXPENSE AND QUARRYING.

Tons of ore mined	15,210
Total mine expense	$79,334
Tons of lime quarried	3,571
Total expense of quarrying	$ 2,535
Cost per ton for	
Extracting ore	$2.520
Development	0.768
Superintendence	0.403
Timbering	0.671
Wood	0.319
Tramming	0.081
General expense	0.155
	$5.217
Cost per ton of limestone quarried for	
Labor	$0.537
Superintendence	0.089
Tramming	0.081
	$0.707

For the latter half of 1893 smelting expenses and weights were:

TABLE IV. SMELTING COSTS.

Tons of ore smelted	15,510
Total furnace expense	$137,959
Pounds of blister copper produced	4,033,135
Cost per ton of ore smelted for	
Labor	$1.243
Superintendence	0.063
Wood	0.282
Timbers	0.002
General expense	0.154
Coke	6.956
Coke lost at Wilcox	0.071
Coke lost at Globe	0.031
	$8.802

For the latter half of 1893 the expenses were, per pound of copper produced:

TABLE V. SUMMARY.

Mining	1.95 cents
Quarrying limestone	0.06 "
Smelting	3.71 "
Total cost per pound of copper	5.98 cents

Commenting upon these results and upon the almost extinct art of blister-copper smelting of oxidized copper ores, one notes, first of all, the high content of the resultant slag in copper. The ore was of a good percentage in copper, containing on an average 35% silica, yet it made 83% of its weight in slag. Had the ore contained 50 to 60% silica, as was the case with that smelted by the writer at Santa Rita, N. M., in 1899, the proportion of slag, and consequently of copper cost, would be in the same measure increased. Mr. Cooper, smelter superintendent of the Calumet & Hecla Mining Co., states that he has been able, while treating such ores, to bring down the percentage of copper in the slag to nearly 1% by the use of anthracite coal.

GOLD-DREDGING AT WAIPORI, NEW ZEALAND.—At one time 13 dredges were at work on Waipori Flat and its immediate neighborhood in Otago, but the number has been reduced to four. The Perseverance dredge was the last to cease operating. It commenced in January, 1901, and has had a much longer lease of active life than most Otago dredges. In 1905, it worked an area of 11 acres, handling 212,960 cu. yd. of dirt, which yielded 1129 oz. gold, which was valued at £4347. The total quantity of gold obtained by the dredge to the close of 1905, was 8645 oz. valued at £33,285 10s.; from this dividends amounting to £13,500 have been disbursed. The cost of the dredge was £3500; the average weekly cost of working, £40; average yearly cost of repairs, £420; and the yearly cost of coal, £700. The average number of men employed was six, and 45 was the average number of weeks worked during the year.

THE DOS ESTRELLAS MILL.

Written for the MINING AND SCIENTIFIC PRESS
By an Occasional Contributor.

The mines and two mills of the Compañia Minera Las Dos Estrellas are in the Tlalpujahua district, in the State of Michoacan, but within three miles of El Oro, in the State of Mexico. In fact the Dos Estrellas, geologically speaking, is in the same district as the mines of El Oro. The principal vein of the Dos Estrellas strikes through a schist, capped by andesite, like the parallel lode of the El Oro mine. Its strike is nearly northwest-southeast, with a dip of 70°. It is opened by two adits, both equipped with double tracks and electric haulage. Six Baldwin-Westinghouse 5-ton locomotives are in use. The first adit is 700 m. long, the second 580 m.

The Dos Estrellas Cyanide Mill.

Near the portal of the first adit is mill No. 1, which has been in operation several years. At the entrance to the second adit is mill No. 2, which is practically a new plant. The two adits, nearly parallel to each other, are over half a mile apart and both cut the main vein at the same angle and on the same level, and at such depth as to give a great amount of stoping ground above the haulage level. The width of the main vein, which is called the Veta Verde, is stated to average about 15 m., the length of the ore-shoot being 2000 m. The gangue is quartz. That part of the property opened by adit No. 1 is known as the Dos Estrellas and that opened by adit No. 2 is called the Cedro. The ore from the Dos Estrellas carries 12 to 15 gm. gold and 200 to 240 gm. silver; that from the Cedro carries 10 to 13 gm. gold and 95 to 120 gm. silver. The ores from both parts are highly silicious. The silver is in the form of sulphide and chloride, as well as native; the gold is partly free and partly mixed with the silver sulphide. Besides the principal vein, the company has three other veins of sulphide ore. These are opened by cross-cuts driven from the workings on the principal vein. These sulphide veins are being developed, and the ore from them is now being milled. As this ore requires wet concentration, it is probable that a suitable equipment may be installed later. The mine is fully equipped with electric appliances, with transformers underground, the workings being illuminated by the electricity that comes from the Hecaxa falls, 300 km. distant.

The ores from the principal vein are crushed in stamp-batteries, classified, re-ground in tube-mills, and subjected to cyanide treatment for the extraction of the gold and silver. Mill No. 1 has 130 stamps, crushing the ore in a cyanide solution through 20 to 30-mesh screens. In passing from the batteries to the tube-mills the pulp is so classified as to separate the slime from the sand. There are 4 tube-mills in this plant, each 24 ft. long by 5 ft. diam., lined with El Oro ribbed lining, cast from chrome steel and scrap iron. It is stated that one set of such liners has been in use 11 months. The tube-mills reduce the pulp so that 75% of it will pass 80-mesh screens. This product is classified in cones, the overflow slime passing to agitating-vats, and the sand to the sand-vats for leaching. First the sand is given washes of 0.22% cyanide solution, then discharged into a second set of vats, in which is given washes of 0.4% solution, and this is followed by washes of 0.12% solution. In the slime treatment part of the decanted solution passes to the

zinc-boxes and the remainder is pumped to the return-solution vats that supply the batteries. The stamp-duty in this mill is 3.48 tons per stamp in 24 hr. Burt filter-presses are being installed here to handle the final slime. In this mill 43% of the material is treated as sand and 57% as slime.

Mill No. 2 has 120 stamps, crushing in cyanide solution. This is followed by classification, tube-mill pulverization, and cyanidation of the sand and slime separately as in mill No. 1. Here are 5 tube-mills in operation. They are the Allis-Chalmers type, 24 by 5 ft. The tube-mill product is divided as 36% sand and 64% slime. Of the sands, 57% will pass 80-mesh screens and 12 to 15% will pass 200-mesh. The sand, after passing to sand-receivers, thence to leaching vats, is first given washes of 0.4% solution, followed by washes of 0.12% solution. The sand is discharged by Blaisdell excavators and Robins conveyors. A 48-ft. tailing-wheel is being installed for elevating a portion of the material to be re-ground in the tube-mills. In this plant all the slime that overflows from the classifiers is treated to mechanical agitation and decantation in vats 36 by 10 ft. The discharge is run from these vats into others that are 36 by 20 ft., where the slime receives continuous agitation for 20 hr., thence to another set of vats 36 by 20 ft. in size, without agitators, for final settling. The Burt filters are also being installed in this mill. The stamp-duty in mill No. 2 is 3.55 tons per stamp in 24 hours.

The precipitate at mill No. 1 carries 75% metal, at No. 2 about 60%. In both mills they use 100 gm. of lead acetate per ton of ore and about 8 to 10 kg. lime. The cyanide consumption amounts to 1.33 lb. per ton of ore. An extraction of 88% of the gold and 64.5 % of the silver is obtained in mill No. 1; in mill No. 2 the extraction is 90% of the gold and 53.4% of the silver. This is for the first 11 months of 1907. Both mills are run by electricity.

The average operating costs per ton for the first ten months of 1907 are as follows (on 259,789 dry tons—the production for the 10 months):

	Pesos.
Milling	1.24
Cyaniding	1.70
Mining (including development at the rate of 1100 m. per month)	4.96
Assaying	0.07
General expenses	0.91
Taxes on ore	0.30
	9.18

The railroad from El Oro to the Dos Estrellas mills belongs to the Dos Estrellas company and is being changed to an electric line. The Dos Estrellas property belongs to F. J. Fournier and associates. On the operating staff are the following: Henri Bossuat, general manager; H. Jouanen, assistant manager; G. Gonzales and O. Lopez, mine superintendents; Walter Neal, superintendent of cyanide work; Thos. Dwyer, superintendent of mill No. 1, and W. H. Armstrong of mill No. 2.

In Colorado there are many occurrences of uranium ore in the form of carnotite.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

F. A. M., of Murphy, sends a specimen of manganese dioxide, Psilomelane.

A small piece of black stalactitic Limonite was sent by G. E. W., of Los Angeles.

Quartz and Calcite or Dolomite stained by Limonite was sent by C. B., of Stemple, Montana.

The green mineral sent by A. C. R., of Lower California, is Garnierite, the silicate of nickel.

A rock containing small foliated plates of Molybdenite was received from G. B., of Goleonda, Nevada.

W. M. B., of Steamboat, Nev., sends a soft white hydrous silicate of aluminum, perhaps Allophane or one of the clays.

S. O. M., of Sweetwater, Nev., sends: No. 1, Tremolite; No. 2, Slate; No. 3, Basalt; No. 4 and 5, yellowish green Garnet; No. 6, Porphyrite.

E. E. N., of Nogales, Ariz., sends: No. 1, Granite; No. 2 and 3, coarse Granite or Pegmatite; No. 4, Syenite; No. 5, Hornblende-Diorite.

The three specimens of rock from Wallace, Ida., marked A, are: No. 1, Greenstone, quite chloritized; No. 2, Diabase; No. 3, Diabase with Asbestos and greenish Quartz.

Specimens sent by D. G., of Terrazas, Mex., are: No. 1, lost in transit; No. 2, mixture of Galena, lead carbonate, and Limonite; No. 3, massive Limonite; No. 4, rock with oxidized Pyrite.

The specimens sent by F. H. C., of East Auburn, were mainly schists containing Pyrite, and have become altered by the action of sulphuric acid formed from the decomposition of the pyrite.

The specimens sent by R. H. H., of Carson City, Nev., are: No. 1, green copper carbonate in a talcose rock; No. 2, specular Hematite; No. 3, Essonite-Garnet in rock with Gypsum; No. 4, Chalcocite and Chrysocolla.

R. I. G., of Fairview, Nev., sends: No. 10, Dolomite; No. 11, Diabase; No. 12, altered rock containing Limonite; No. 13, Hornblende-Andesite; No. 14, altered rock, perhaps an Andesite; No. 15, Melaphyr; No. 16, altered feldspathic rock; No. 17, Rhyolite.

Rocks from El Oro, Mex., marked R. R. M., are: No. 1, pyritic rock with greenish stains due to the protoxide of Iron; No. 2, Quartz-Breccia stained by Limonite; No. 3 to 7, lost in transit; No. 8, Chalcopyrite in quartz with Malachite and Limonite stains; No. 9, lost; No. 10 and 11, pieces from the oxidized zone of Chalcopyrite showing Limonite, Malachite, Azurite, and Gypsum.

MINING IN THE WRANGELL DISTRICT, ALASKA.

The copper prospects and gold placers of the Chitina valley, Alaska, were examined during the summer of 1907 by geologists of the United States Geological Survey. Most of these prospects lie north of the river, on the south slopes of the Wrangell mountains, extending from Kotsina river nearly to the head of Chitistone river, a distance of about 70 miles. Other prospects are located south of Chitina river, in the neighborhood of Taral, an Indian village on Copper river, but these have not yet received as much attention as those of the Wrangell mountains.

The gold placers in operation in the Chitina valley last summer are confined to Chititu and Dan creeks, two southern tributaries of the north branch of the Chitina known as Nizina river. Both creeks have been small producers for several years and promise to increase their output considerably during the coming season.

The Chitina River region was first visited by a Survey party in 1900, when a geologic and topographic reconnaissance map was made under the direction of F. C. Schrader and A. C. Spencer. The report on this work is now out of print. Later, in 1902, the western portion of the region, including only Kotsina river and Elliott creek, was visited by W. C. Mendenhall, whose report, entitled 'The Geology of the Central Copper River Region,' published as Professional Paper No. 41 of the Survey, is the only one still available for distribution. The explorations in 1907 in the Chitina valley were made by F. H. Moffit and A. G. Maddren, who spent about two months in examining the copper prospects and gold placers of the valley. Copper prospects exist at a small number of localities between Kotsina and Chitistone rivers near the contact of the Nikolai greenstone and the overlying heavy bedded Chitistone limestone. This contact can be traced with little difficulty, although it is in places covered by later sediments, and it has served as a guide for prospecting ever since the region was opened. The accompanying map shows the localities referred to.

Most of the ores of the Kotsina region are of one general type. Nearly all the workings, some of which are open-cuts and others short tunnels, show bornite, chalcocite, and, less frequently, chalcopyrite in greenstone. At one locality the copper ores are in limestone. The greenstone has undergone movements which have produced crushing and faulting but have not otherwise greatly altered the original condition of the rock, at least so far as can be seen in a hand specimen. A development of secondary minerals or of cleavage in the greenstone has taken place locally, however. The copper sulphides are present as lenses and stringers in the greenstone, and in most places occur in sheared zones of the rock or associated with joints and fault-planes.

All of the deposits examined by the Survey party on Elliott creek are of the type just described. They occur in the greenstone, many of them within short vertical distances of the Chitistone limestone. Nearly all the property, except a few of the easternmost claims, lie on the north side of Elliott creek and are controlled by the Hubbard-Elliott Copper Mine Development Co. In July ten men were employed on the property and were engaged chiefly in doing assessment work on unpatented claims and in building cabins for offices and quarters. It was expected to increase the working force and resume work on the adit known as the Elizabeth tunnel, which at that time had been driven a distance of about 250 ft. Short tunnels from 10 to 40 ft. long have been driven on several of the other patented claims, but no work has been done on them for some time, as, because of the very short season, the difficulty of procuring supplies, and the impossibility of making ore shipments until better transportation facilities are obtained, it has been necessary to devote all available time to representing the unpatented claims.

The most extensive operations on Kotsina river were under the direction of E. F. Gray of the Great Northern Development Co. About 75 or 80 men were employed in prospecting claims, most of which lie in the upper Kotsina valley in the vicinity of Ames and Roaring creeks. Some claims on Rock creek are also under the control of this company, as well as claims on Iron mountain south of the head of Elliott creek and near Kennicott glacier. No orebodies had been encountered at the time the Survey party left, though encouraging prospects had been found on Rock creek. Prospecting is carried on chiefly by tunnels in places where brown iron stains indicate the oxidation of sulphide minerals, and not less than a dozen of these tunnels have been started on the various properties. A small saw-mill erected last summer furnishes lumber for building and mining purposes, and during the early summer connection with the Government telegraph at Tonsina was established by a telephone line from the main camp on Kotsina river. A. T. Crawford had a small force of men doing assessment work on Khvesna river and several other tributaries of the Kotsina, such as Roaring creek and Copper creek. On Peacock and Surprise creeks the Alaska Kotsina Co. employed a small force of men in representing claims and in making improvements, such as building trails and constructing cabins preparatory to more active development next summer. The prospects are of the type common in the Kotsina region, except those on Shower gulch, where native copper occurs in an amygdaloidal greenstone.

Another company operating on the Kotsina is the California-Alaska Co., engaged like all the other operators of this region, in doing work necessary to hold claims. One claim on Copper creek is of peculiar interest, as it is one of the few in the western part of this Chitina belt where the copper minerals are found in the Chitistone limestone. Bornite with chalcopyrite, azurite, and malachite are the minerals seen in the surface openings on this claim.

From Kotsina river the Survey party crossed the high ridge on the south to the Kuskulana drainage. Most of the prospects of this locality are within a few miles of the glacier and include claims on Slatka, Trail, Dry, and Porcupine creeks as well as the

Kuskulana itself, but the most extensive operations were those on Nugget creek, on what are known as the McCarthy properties. With one exception the occurrence of copper here is of the same general type that is found farther west. All the prospects are in greenstone, and gangue minerals are generally absent except at the claim known as the Valdez. Here a short tunnel cuts a vein of calcite carrying bornite and chalcopyrite. The maximum thickness of this vein is approximately 24 ft., but it has been traced only a short distance along the strike in either direction. A number of claims have been staked in the somewhat isolated mountain mass between the Chokosna and the head of Gilahina rivers, but nobody was on the ground and the claims were not visited by the Survey party. Two groups of properties on Lakina river, known as the Greer and Lynch properties, differ from all the prospects to the west except those of Shower gulch in that most of the ore is native copper. The copper is associated with faults or joint-planes in amygdaloidal greenstone and, in places is contained in a quartz filling. Only assessment work has been done at this locality up to this time. A group of claims known as the Tjosevig is located on Hidden creek, west of Kennicott glacier. The copper minerals are chalcocite, bornite, and chalcopyrite in greenstone, associated with what may possibly be an intrusive sill. A small force of men was at work on these claims during the summer. A few miles farther south, in the main valley of the glacier, some prospecting was being done by the Great Northern Development Co.

The largest and by far the most valuable body of copper ore now known to be present in the Chitina valley is the Bonanza, which, with a few other claims of similar character, but of less evident value, constitute the property of the Kennicott Mines Co. The ore is almost entirely chalcocite and is a replacement of limestone along a series of perpendicular fractures or fault-planes. This orebody lies at an elevation of about 6000 ft. above sea-level. It is in the Chitistone limestone only a few feet above its contact with the underlying greenstone, but so far as is now known does not penetrate the greenstone. The fractures in the limestone have taken place with very little displacement and have not been traced downward into the greenstone nor can they be traced for more than a short distance horizontally. The ore is well exposed on the surface and has been cross-cut by two tunnels, but no further development work has been done on the orebody itself. The last summer was spent in preparation for active development work next year. A good trail was built from the mine to the mouth of National creek, where the office, quarters for men, and ore-bins are to be built, and thence down the east side of Kennicott glacier to Kennicott river. A wire tramway is under construction to carry ore from the mine to the bins, whence it may be transported to steamboats on Chitina river or to the railroad, when that is completed.

East of the Bonanza are the Nikolai property, on Nikolai creek, a tributary of McCarthy creek, and the copper prospects of Chitistone river and Dan creek. The Nikolai was the first claim patented in this region, and since the patent was granted no further work has been done. Two companies were prospecting on Chitistone river, and a number of persons were engaged in the same work or in representing claims staked in previous years. The Houghton-Alaska Exploration Co. is most active and has done more development work than all the others combined. On the north side of Chitistone river this company drove a 90-ft. tunnel in the greenstone and on the south side two short tunnels in the limestone just above the contact, to test the value of ores outcropping on the surface. The second company, the Alaska United Copper Exploration Co., employed most of its men in representing claims and in the construction of trails and a cabin. Among other properties that have attracted attention is the Chiti claim on Glacier creek, a tributary of Chitistone river. The ore is native copper associated with chalcocite and a little cuprite in amygdaloidal greenstone.

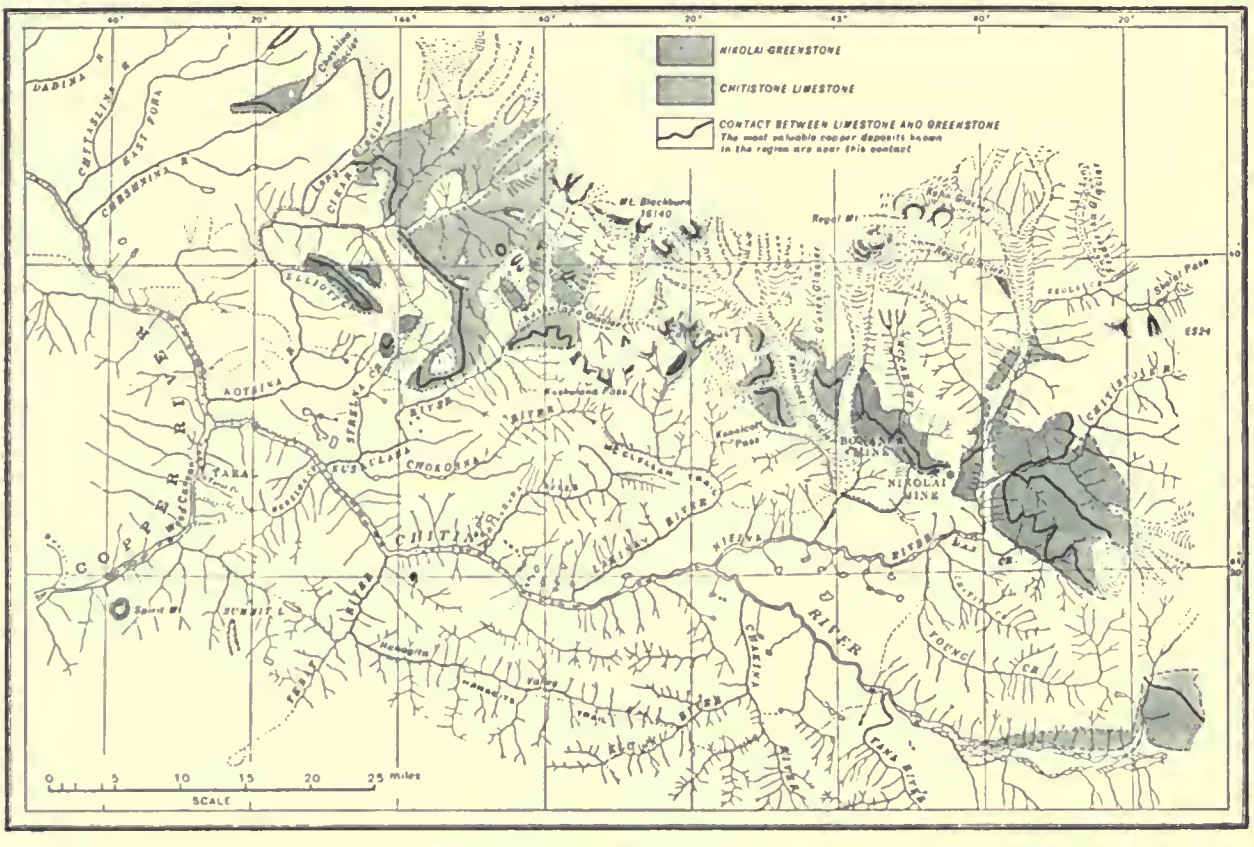
Placer mining in the Chitina valley is confined to Chititu and Dan creeks. Dan creek runs nearly parallel to Chititu creek and is only 6 or 7 miles north of it. The lower part of Dan creek is under a single control and is generally known as the Williams group. This ground has been well prospected and surveys for a hydraulic plant were made during the summer. Only a small amount of gold was mined this year, since the ground can be handled much more economically when the plant has been installed. Some gold was taken from Copper creek, the chief fork of Dan creek. On Chititu creek, G. M. Esterly has installed a hydraulic plant, which is in condition to begin active work as soon as the season opens in the spring. It includes, besides flume, pipelines, and the usual appointments, an electric-light plant and a well equipped saw-mill with planer, edger, and other appliances. This plant has been installed in an unusually business-like and efficient manner. Farther up on Chititu creek a hydraulic plant, the property of Frank Kernan, had a successful season.

The heaviest handicap under which prospecting has been carried on in all this interior country is the great cost of transportation. It is hoped that within the next two years, with the completion of the railroad, this difficulty may be removed. In July a small light-draft steamboat named the *Chitina* made her first trip from Abercrombie Rapids to Copper Center on Copper river and to the mouth of the Nizina on Chitina river. Most of the material for her construction was hauled in last winter over the snow from Valdez to the mouth of Tasnuna river, where she was built. She was completed in July, but after making one trip was hauled out on the river bank at Tasnuna. She will probably be used next summer in transporting supplies for the Copper River & Northwestern Railroad. This road is now being built from Cordova bay to Copper and Chitina rivers. From Abercrombie canyon a branch line will run to Katalla and the Bering River coalfields. The southern terminal of this railroad was recently changed from Katalla to Cordova bay, a

change which is probably due to the great difficulty of lightering freight from steamships at Katalla under present conditions and to the great cost and the long time required to build a breakwater behind which ships could lie at Katalla. Much prospecting and considerable development work has been carried on in the Prince William Sound country during the summer. Knight Island properties have been especially active for more than a year but it can not be said that a copper mine has yet been developed there. After Knight island, Latouche island and the Orca region have been most prospected.

Among the older properties, that at Ellamar has been idle during part of the summer, it is said because of labor troubles. During the summer the shaft was sunk to the 600-ft. level and 650 ft. of drift was made. The ore production, however, was much reduced. On Galena bay the erection of an aerial tram, 5000 ft. long, from the mine to the beach, was begun, and bunkers were being constructed at the beach. Only a little work was done on Bowlder bay, most of it by the Reynolds-Alaska Development Co., which extended its main adit. Two small shipments of ore, nearly 400 tons, were made by the Standard Copper Co. on Landlocked bay. A small shipment of high-grade ore was made from the Dickey prospects at the north end of the bay, where a tramway and wharf have been built. At Latouche, the Beatson property, known as the Bonanza and not to be confused with the Bonanza on Kennicott river in the interior, was the only property that made regular shipments. A cross-cut adit 900 ft. long was driven, cutting the orebody at a level 90 ft. below the old tunnel. The Reynolds-Alaska Development Co. has erected a wharf, electric-light plant, a trading store, and a number of houses on their property on Horseshoe bay, on the west side of Latouche island. A shaft was sunk on one of their claims and a small shipment of ore was made. East of the Bonanza mine, on the Barrack claims, active development work was in progress. A wharf, ore bunkers, and tramway were under construction and a small amount of ore was shipped.

A great many claims have been staked on Knight island, but most of the locations were made within a year or two, so that less work has been done here than on the neighboring island Latouche. Among those carrying on active development is the Hubbard-Elliott Co., whose property is on the west side of Knight island at Dryer bay. A tramway with other equipment was installed during the summer and a small shipment of ore is reported. Prince William Sound properties enjoy a great advantage over the interior region in that nearly all of them are within comparatively easy reach of tide water and that their development is not dependent on expensive railroad construction.



Map of the Copper River District, Alaska.

From Professional Paper No. 41, U. S. Geological Survey.

THE MINERAL PRODUCTION OF CALIFORNIA.—Some 47 mineral substances are now being mined in California, and the combined value exceeded $51,000,000 in 1906, and is estimated to be increasing at the rate of about $10,000,000 per year. The greatest recent advance in mineral production has been made in petroleum, an industry in which California now ranks second in the world. According to the best available statistics the output of California petroleum for 1906 reached the enormous total of 35,000,000 barrels, with a value of $10,000,000. Vast enterprises in pipe-laying are now in progress and some of them completed, for connecting interior oilfields with tide-water.

OIL INDUSTRY OF THE UNITED STATES.

Government Report on the Standard Oil Company.

The third report of the Commissioner of Corporations on the petroleum industry of the United States (which was submitted to President Roosevelt in August, 1907) has just been made public in a volume of more than 1000 pages. The investigation of the oil business by the Bureau of Corporations under the direction of the Secretary of Commerce and Labor was begun in the early part of 1905 by a corps of special examiners, attorneys, and agents under the supervision of Mr. Garfield, then Commissioner, and was completed in the latter part of 1906. Three volumes have been published:

(a) Transportation of Petroleum.

(b) Petroleum Industry, Part 1, Position of the Standard Oil Co.

(c) Petroleum Industry, Part 2, Prices and Profits.

The present review deals only with the last named report.

In his letter of submittal to the President, Mr. Herbert Knox Smith, the present Commissioner of Corporations, states that "from the point of view of the public, this is one of the most important parts of the report," previous parts having "had to do with means and methods," while "the present report on the other hand sets forth the results of such methods and the effect thereof on the consumer and on the profits of the Standard Oil Co." The Commissioner concludes that "The Standard is the most conspicuous example of a combination which maintains a substantial monopoly, not by superiority of service and by charging reasonable prices, but by unfair methods of destroying competition. * * * It has raised prices instead of lowering them. * * * Some of the unfair and illegal means * * * have been proved in the reports already published. * * * In the present report (it is established that) during the last eight years covered by this report (1898 to 1905) it has raised both prices and margins. * * * The Standard has superior efficiency in running its own business; it has an equal efficiency in destroying the business of competitors. * * * Its profits are far above the highest possible standard," on a reasonable commercial basis.

The report contains 736 pages, including 251 special tables and diagrams, following with 212 pages of general tables; the whole comprising an exhaustive argumentative study of profits and prices of the products of petroleum which, the Commissioner states, "is necessarily chiefly a study of the policy of the Standard Oil Co." The chief subject features are:

1. Crude oil; fields, prices, relation to supply of products.
2. Illuminating oil: sources of supply, distribution, prices.
3. Gasoline and stove oil; sources, importance, prices.
4. Lubricating oil for railroad equipment, methods, prices.
5. Margins between crude oil and its products.
6. Discriminations in domestic prices.
7. Foreign prices of American oil.
8. Profits and domination of the Standard Oil Co.

Of the six crude-oil fields the report says that only the Appalachian (or Pennsylvania, as it is better known) and the Lima-Indiana need to be considered for most purposes in the general discussion of price movements, for the reason that comparatively small proportions of the crude outputs of the other large fields are handled by the refineries; as shown by the following statement for the year 1904—a representative year:

Name of Field.	Total Crude Oil Produced. Bbl. of 42 Gal.	Consumed by Refineries. Bbl. of 42 Gal.	Illuminating Oil Produced. Bbl. of 50 Gal.
Pennsylvania	31,408,567	27,628,000	15,830,000
Lima-Indiana	24,689,184	24,230,000	8,700,000
Mid-Continent	5,617,527	1,056,600	370,000
Gulf	25,200,381	864,700	1,300,000
Colorado	501,000	440,000	125,000
California	29,649,434	4,167,000	650,000

The average annual price of Pennsylvania crude for about 20 years preceding 1898, with the exception of three years (1883, 1895, 1896) was below $1 per bbl.; from 1899 to 1906, both inclusive, the prices fluctuated from $1.21 in 1901 to $1.62 in 1904. The Lima-Indiana prices for the same period, 1898 to 1906, were from 61c. in 1898 to $1.16 in 1903. Previous to 1895 the price was below 50c. The report says that it is "probable that the Standard kept the price down in order to enable it to acquire extensive oil leases at a low price, after which it rapidly increased the prices. * * * There has been a marked similarity in the price movements between Pennsylvania and Lima crude during recent years." The Lima is not of as good quality as the Pennsylvania. The new field brought in about the close of 1905, in Illinois, and included in the Lima-Indiana field, has produced a refining oil about equal to the Lima, but the price has been much lower, due in part to the inability of the pipe-lines to handle the rapidly increasing production.

The Mid-Continent field has come to be a factor in prices of both crude and refined; but the report says that the general influence scarcely dates back of 1905, during which year a pipe-line was established from this field to Whiting. A separate report on the Mid-Continent field will be submitted by the Commissioner, owing to the complication and importance of the causes affecting the prices in Kansas.

In the Gulf field only the Corsicana district may be said to be controlled by the Standard in the fixing of the crude prices. A larger part of the crude in the southeast Texas and Louisiana districts is sold on the short contract basis, and prices are considerably lower than in Corsicana, whose product is largely consumed by the Standard refinery.

Colorado crude is chiefly consumed by the refineries that own the wells, and the products are marketed within a clearly defined area, so that the prices have substantially no influence on the prices of other crude oils or their products.

California crude has had substantially no effect on other fields or the general market, as only a small percentage is refined and there is such a variety of

quality, and variances in prices; and the products of the refineries are marketed within a sharply defined area. Five-sixths of the crude going to the refineries is treated by the Standard Oil Co. at Point Richmond. Owing to the peculiar conditions, particularly in connection with the fuel-oil business, California will require special discussion in a special report hereafter to be published.

"The yield of the crude is naturally an important consideration. * * * Hence the prices of Pennsylvania and Lima crudes are comparatively high and prices of Texas and California are relatively low. * * * Kansas crude occupies an anomalous position, having a high percentage of illuminating * * * yet it has been reduced recently to a very low price."

Following is a comparison of yields and prices in December, 1904, of the crudes in the five essential fields:

	Naphtha. %	Illuminating. %	Average Price. Per Bbl.
Pennsylvania	12	67	$1.57
Lima-Indiana	11.5	43	1.026
Mid-Continent	11	41	0.843
Gulf	3	15	0.311
California	6	18	*0.60

*Estimated.

The parallelism between the proportions and the prices is much closer in December, 1904, than in December, 1905.

Confining attention to Pennsylvania and Lima, the yield is about 3 to 2 in favor of Pennsylvania crude; the ratio of prices at the end of 1904 was nearly 3 to 2 ($1.57 to $1.026); at the end of 1905 the ratio of prices was about 9 to 5 ($1.58 to $0.915). So the ratio of yield between Pennsylvania and Mid-Continent was about 3 to 2 and the ratio of prices in December, 1904, was about as 9 to 5; and at the end of 1905 the price of Mid-Continent crude had declined to 52c. per bbl. and later to 39c.; meanwhile the Pennsylvania crude, although declining in 1905, was advanced in 1906 and reached $1.78 in 1907, while the Mid-Continent was advanced only 2c. per bbl.; and in the same period Lima-Indiana advanced; although in the beginning the Kansas crude was slightly higher than Lima, but in the middle of 1904 it dropped and then very rapidly until the price was less than half the price of Lima. Kansas was 35c. lower than Pennsylvania in February, 1903, and $1.07 lower in November, 1905; and in December, 1906, the margin was $1.19. "While the Standard may * * * have found the production greater than it could handle, nevertheless it has treated the Mid-Continent producers unfairly because it has used all its efforts to prevent independent pipe-lines and refineries from being established."

Further demonstration of the situation just described is made by a series of tables and diagrams regarding the comparison of the average annual stocks of crude with the average annual prices, and elaborated in the text. Briefly stated, the result shown is: "With the single exception of the movement from 1899 to 1900 * * * as the combined stocks (of the Pennsylvania and the Lima-Indiana fields) increased, prices decreased; and as the combined stocks decreased, prices increased" from 1894 to 1904. From 1904 to 1905 the price of Pennsylvania crude fell considerably, notwithstanding the decrease in the combined stocks of Pennsylvania and Lima-Indiana crude, due, probably, the report says, to the rapid increase in the stocks of Mid-Continent crude; which stocks had largely increased in 1904 also, but had no influence until 1905.

Sources of supply, distribution, and prices of illuminating oil are elaborately set forth in the report by maps, tables, and diagrams. The map of territorial distribution from Standard Oil Co. refineries indicates 17 refineries, which are here named in the order of their comparative sizes: Whiting, New York, Franklin, Philadelphia, Buffalo, Olean, Baltimore, Richmond, Cleveland, Lima, Pittsburg, Sugar Creek, Florence, Neodesha, Parkersburg, Chaison, Corsicana. The map shows six divisions of distribution, making two divisions of the Western (the Pacific Coast and Rocky Mountain divisions). Reading from west to east: The Pacific Coast is supplied from Richmond; the Rocky Mountain from Florence; Texas and parts of New Mexico, Oklahoma, Arkansas, and Louisiana, supplied from Chaison and Corsicana; Kansas, Nebraska, western Missouri, and western Iowa are supplied from Sugar Creek and Neodesha; the Central States, from Whiting and Lima and Cleveland; the Atlantic Coast States are supplied from the refineries of Buffalo, Olean, Pittsburg, Parkersburg, New York, Philadelphia, Baltimore.

From a table of prices of waterwhite illuminating oil, and cost of transportation, to retailers, by States and groups, the following is taken for the year 1904:

	Average Price per Gal. Less Transport. Cents.	Average Cost of Transport. Cents.
North Atlantic	9.5	0.5
South Atlantic	10.3	1.8
North Central	9.6	0.9
South Central	11.2	2.1
Western	13.7	3.1
United States	10.2	1.2

The table contains 49 prices and costs of transportation averaged from 1830 quotations. Some of the variations in prices of oil and cost of transportation between States are shown by the following selections from the table:

	Price per Gal. Cents.	Cost of Transport. Cents.
Delaware	7.7	0.7
Pennsylvania	8.7	0.6
Rhode Island	9.6	0.5
New York	10.0	0.3
South Carolina	10.8	2.5
Texas	11.6	1.5
Colorado	16.2	2.3
Nevada	16.4	5.6
Washington	15.7	2.7
California	11.1	1.2
Oregon	15.3	3.3

Data obtained from retail dealers show a predominance of tank-wagon delivery to the extent that of 3854 towns reported there were 3061 towns receiving oil in tank-wagons, and of that number the tank-wagon is used exclusively in 2517 towns; the next

important method is by iron and wooden barrels; while only 320 receive oil in cases.

Gasolene, next to illuminating oil, is the most important product of the refineries, the greater portion of which, particularly in recent years, has been either stove gasolene or motor gasolene. The report states that for December, 1904, price records were obtained representing 713 towns, mostly delivered by tank-wagons, covering the North Central, western South Central, Rocky Mountain and Pacific Coast divisions; full data for the Pacific Coast since 1897, and similar data from 1903 to 1905 for the Rocky Mountain division were secured from the Standard; these prices for the Western territory correspond quite closely to that of the North Central States, except that on the Pacific Coast the gross prices show less advance since 1903 on account of the establishment of the Standard refinery at Richmond, Cal. The North Central prices correspond also with prices in other divisions, and for that reason have been taken as typical of the movement of the entire country. The tables show the average price of gasolene, less freight, and the prices of Lima crude and of Pennsylvania crude, with the margin between the gasolene and the crude, demonstrating that in the period 1901-1905, particularly, there was a marked advance in the margin from January, 1901, to the middle of 1903 of 3.3c. per gal. (6.9 to 10.2); thence to the end of 1904 the margin declined 1.9c.; but in the first six months of 1905 the margin again ranges higher, increasing from 8.5 to 8.7 cents.

The significant feature of the lubricating oil industry presented by the report is the domination of the Standard Oil Co. in its dealing with the railroads. The report cites particularly the case of the Norfolk & Western Railway. This company, after making thorough and satisfactory tests of the relative efficiency of the lubricating oils of the Standard Oil Co. and two independent companies, and establishing the fact that the independents produced fully as good quality, and that one of them a preferable oil at a smaller cost, the Standard continued to control the sale of the lubricants to this as to other companies. The report goes into this matter fully, giving the record of the tests, the forms of contracts, and complete data. A tabulated statement is also given showing the wide difference in the net prices paid by different railroads.

Margins between crude oil prices and prices of products have increased since 1897, and added greatly to the profits of the Standard, according to the data in the report. It is shown that the average margin for all products combined for 1898 and 1899 was 6.1c.; for 1900 to 1902, 7.1c.; January, 1902, to June, 1905, 7.8c. It is possible, the report states, that some part of the increase in margins has been due to increased cost of pipe-line transportation, refining and marketing, but only a very small amount per gallon.

Discriminations in the domestic market as to prices in various cities are made a considerable part of the text and tabulated construction of the report. As an illustration the following prices, less freight, of illuminating oil in December, 1904, are given: New York, 10.5 cents per gal.; Boston, 10.8c.; Worcester, 7.5; Cleveland, 7; Cincinnati, 6.4; Augusta, Ga., 8.2; Atlanta, 10.9; Kansas City, 9.9; St. Joseph, 10.4; Los Angeles, 6.7; San Francisco, 12.3; Seattle, 14.5; Denver, 14.4; Butte, 16.6. Only a small fraction of these differences, the report says, is due to difference in cost. Referring to the differences in prices on the Pacific Coast, the Commissioner in his letter of submittal says: "One of the most striking instances is in California, where the Standard carries oil from its great refinery near San Francisco, several hundred miles by water and rail, and sells it in Southern California for several cents less than is charged for the same oil in San Francisco."

A very large proportion of the petroleum products of the United States, says the report, is exported; 55 to 60% of the illuminating oil is sent abroad; and that there is a remarkable excess in the American above the foreign price. During the latter half of 1904 the average prices were: United States, 10.3c. per gal. for illuminating oil; Germany, 6.92c.; United Kingdom, 6.42; Denmark, 6.49; after allowing 1 cent for difference in quality the excess ranged from 2.38 to 2.88c. That there was no oversupply in the United States, as claimed by the Standard, the report states was proved by the fact that the Standard shipped more than 2,500,000 bbl. of illuminating oil from Russia to various European and Asiatic countries, from November, 1902, to the end of the first half of 1905.

Two chapters of the report are devoted to discussion and data regarding the profits, and the sources of domination of the Standard Oil Co. It is shown that for the 25 years, 1882 to 1906, inclusive, the total amount of dividends paid was $551,992,904, an annual average of $22,077,000; and the average amount of trust certificates or stock was $91,434,574; the profits in excess of dividends for the same period amounted to $79,536,025; and these profits are based on an investment that at the end of 1906 was valued at about $75,000,000.

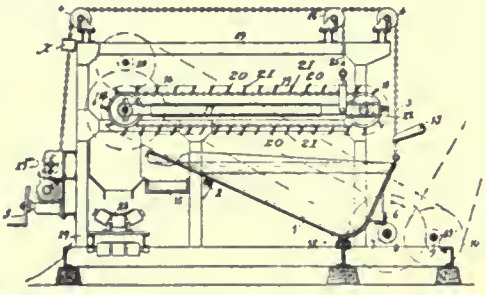
THEORETICALLY, a miner working underground requires only 6½ cu. ft. of fresh air per minute for respiration and the absorption of moisture and the dilution of carbonic acid gas. This assumes that air after having been breathed is immediately removed without mixing with the surrounding atmosphere, a condition impossible to fulfill. Considering that the permissible vitiation of air by carbonic acid is six parts in 10,000, it will be found necessary to provide 66 cu. ft. of air per minute to dilute and carry away the 0.8 cu. ft. of carbonic acid produced per hour by one man. Considering the problem in this light, it is evident that, although an average man at work breathes only about 750 cu. in. air per min., the amount necessary to carry away the gases given off is the important consideration.

A COMPANY formed at Nagasaki, Japan, for the employment of volcanic ashes for cement has realized great profits. Already the exports of this new kind of cement are not less than 700,000 bags per annum. It is shipped to Korea, Sciangai, Formosa, and north China. Sand and portland cement enter into the composition of the new material, but the proportions are not known.

MINING AND METALLURGICAL PATENTS.

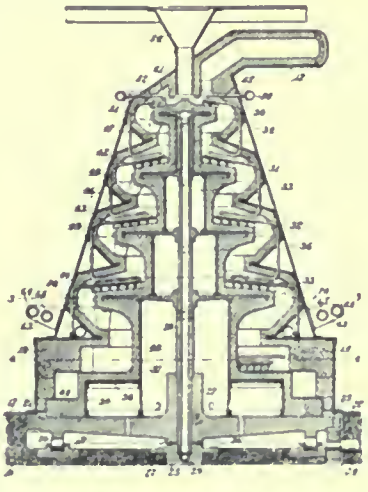
Specially Reported for the MINING AND SCIENTIFIC PRESS.

ORE CONCENTRATOR.—No.876,713; Petrus Härdén, Stockholm, Sweden, assignor to Metallurgiska Aktiebolaget, Stockholm, Sweden, a Corporation of Sweden.



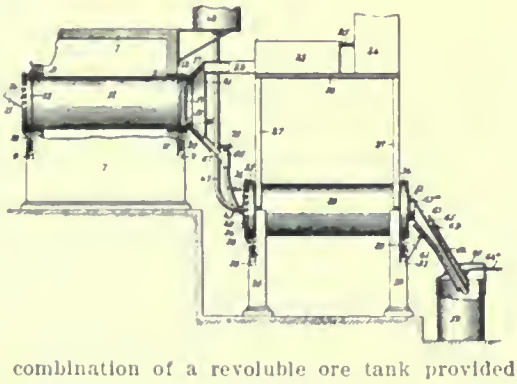
Apparatus for shaking ore pulp, comprising a pivoted receptable, means for shaking it, means for raising the receptable to run off the water, and an endless scraping means with devices for lowering the latter into the receptacle and withdrawing the same therefrom.

FURNACE FOR ROASTING ORES.—No. 876,567; Alva D. Lee, Brookline, Massachusetts.



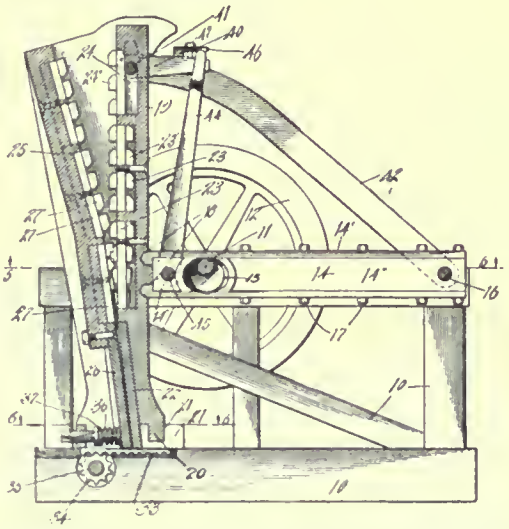
In a roasting furnace provided with an ore inlet at the top, the combination of a hollow revoluble member beneath said inlet; a plurality of projecting shelves secured thereto at various levels; a plurality of cylindrical casings surrounding said revoluble member between said shelves; and means for supplying heat to the bottom of said furnace.

REVOLVING ORE-TANK.—No. 876,539; Allen J. Garver, Clarkston, Wash., assignor to himself and Jonathan McAssey, Clarkston, Washington.



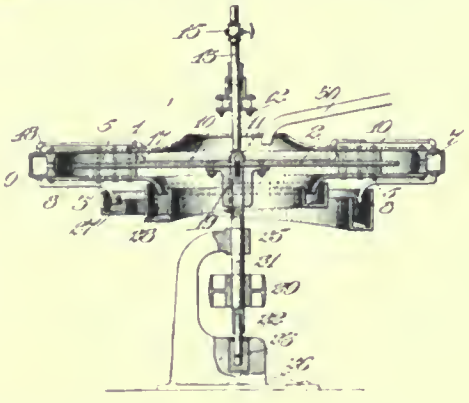
The combination of a revoluble ore tank provided with a disk, a pipe connected with said disk and adapted to discharge comminuted ores into said tank, said pipe being so connected with said disk as to permit the rotation thereof while said ore is being discharged thereinto, a second pipe connected with said disk so as to permit the rotation of said cylinder, said second pipe being adapted to discharge a solution into said cylinder,

ORE-CRUSHING MACHINE.—No. 876,892; John B. Albers, Los Angeles, California.



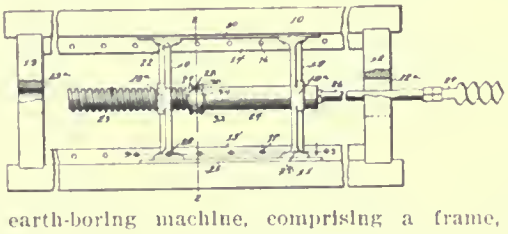
An ore-crushing machine provided with crushing jaws whose upper ends are more widely separated than the lower ends thereof; mechanism to give one of said jaws a vertical motion and the top of the other jaw a movement toward and from the jaw having the vertical motion; and mechanism to hold the lower end of said last jaw in spring pressed engagement with the bottom of the vertically moving jaw.

CENTRIFUGAL CONCENTRATOR.—No. 876,642; Edward Hearing and Fred A. Dudley, Kellogg, Idaho.



A concentrating apparatus consisting of a plurality of horizontally revoluble surperposed disks, independent separating chambers carried by the disks at the periphery thereof and having openings therelnto, each of said chambers consisting of a separate casting independently fitted to the apparatus, means for supplying the separable material to be dellvered outwardly by centrifugal force, and caused to pass over the openings into the separators, and pipes whereby water under pressure is dellvered into the separators so as to form a counter current through the receiving openings.

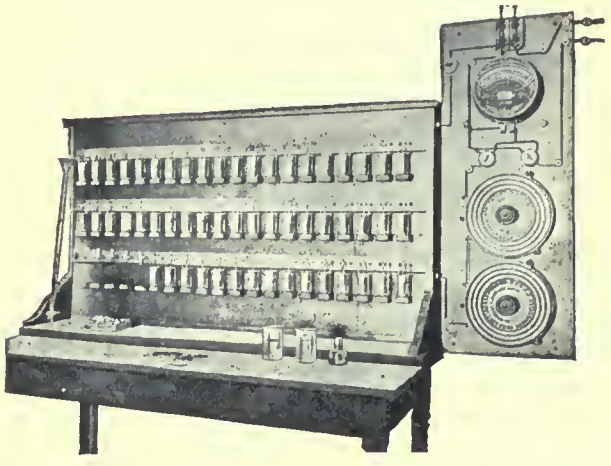
EARTH-BORING MACHINE.—No. 876,048; Patrick Fenton and Frederick W. Waechter, Knoxville, Iowa.



An earth-boring machine, comprising a frame, angle plates on said frame, connected machine heads in said frame and engaging said angle plates, a feed bar mounted in said machine heads, screw connections between said feed bar and one of said machine heads, means for connecting an auger to said feed bar and means for rotating said feed bar.

Electrolytic Assaying.

The increasing demand for greater speed and more accuracy in making daily assays of ores and products from mills treating material containing but very small quantities of lead and copper, has caused the older analytical methods to be supplanted by new ones, devised to meet the needs of modern work. The usual form of electrode in use at the present time consists of platinum cylinders and spirals, or cones and spirals, costing in the vicinity of from $15 to $20 each, making the installation of many units very costly.



In order to overcome this expense, George A. Guess and H. E. T. Haultain have designed and patented a cheaper form of electrode.

The outfits are furnished in cabinet form and can be made up of any number of units. In battery sets they are connected up in parallel and for power current they are connected in series. Suitable rheostats for controlling the current and also ammeters for reading are furnished with each outfit. The cost of the outfit complete for any number of units, including stand, table, batteries, ammeters, rheostats, connectors, beakers, and electrodes, will be found to be less than the cost of the old type of electrodes. In addition, the time necessary to make an estimation is a feature that most readily appeals to all operators, as determinations can be made in three hours, whereas in the old form from ten to twelve hours are necessary.

A pamphlet entitled 'Electrolytic Assaying' will be sent to all interested parties upon application to F. W. Braun, Los Angeles and San Francisco.

Books Received.

'Mining Tables' by F. H. Hatch and E. J. Valentine. Macmillan & Co. Price $1.90. 200 pages. This is a handy volume containing a comparison of the units of weight, measure, currency, mining area, etc., of different countries, together with tables, constants, and other data useful to mining engineers and surveyors. It is well worth the price and ought to prove most useful. For sale by the MINING AND SCIENTIFIC PRESS.

'Hydraulic and Placer Mining' by Eugene B. Wilson. John Wiley & Sons. Price $2.50. 350 pages. This is the second and revised edition of a popular handbook. It contains most of the information needed by those who wish to learn the rudiments of placer mining, while the book includes many data useful even to those who are experienced in this branch of mining. It is nicely illustrated and well printed. For sale by the MINING AND SCIENTIFIC PRESS.

'Specification and Contracts.' By J. A. L. Waddell. This useful volume includes examples for practice in specification and contract writing, together with notes on the law of contracts by John C. Wait. The publishers (The Engineering News Publishing Co.) state that the price of the book has been kept as low as possible, since their aim and that of the authors has been "the advancement of the engineering profession in one of its most important lines." It ought to be an extremely useful book of reference. Price $1. For sale by the MINING AND SCIENTIFIC PRESS.

Commercial Paragraphs.

WILLIAM W. POWER has recently been appointed manager of the electrical department of the Boston branch of the H. W. Johns-Manville Co.

THE GUTTA PERCHA & RUBBER MANUFACTURING CO. announces its removal on Feb. 1 from Alameda to permanent quarters at 67–69 First St., San Francisco.

THE CALIFORNIA ORE TESTING CO. is installing in this City a complete Merrill experimental filtering plant, consisting of slime-press and precipitation-press. Cyanide specialists should go and see it in operation.

THE AMERICAN WELL WORKS, of Aurora, Ill., have issued a new and attractive bulletin (No. 104), describing the construction of their centrifugal pumps and explaining the varied adaptations of this useful piece of machinery.

THE CHRISTMAN COMPANY, of Massillon, Ohio, has issued a well illustrated catalogue describing the special features of its drilling machinery and mine equipment; these include the hollow-rod drill, which has the motion of an ordinary churn-drill. In the rod next the bit there is a steel ball which forms a valve, and as the rod rises and descends, all the material is drawn into it and discharged at the top through the discharge hose.

Catalogues Received.

THE WESTERN ELECTRIC COMPANY announces a new bulletin describing the Beck Flaming Arc Lamps, now manufactured for use on either alternating or direct currents, and so greatly simplified in construction that but little skill is required in operating.

THE JOSEPH DIXON CRUCIBLE CO. of Jersey City, New Jersey, has issued a booklet entitled 'Dixon's Graphite Brushes'; this contains much information useful to all users of graphite brushes and will be of interest to many other mechanical and electrical engineers.

FORT WAYNE ELECTRIC WORKS of Fort Wayne, Ind: 'Bulletin No. 1102,' containing a list of plants operating direct-current direct-connected generators, types MP and MPL; 'Bulletin No. 1103,' describing the series A. C. arc lighting system; and an index to bulletins No. 1001 to 1103.

THE DE REMER WATER WHEEL CO. of Denver, Colo., has sent us the third edition of its catalogue entitled 'De Remer Water Wheels'; in addition to describing the water wheels manufactured by the company, it contains in tables much useful information for the hydraulic engineer.

THE A. LIETZ COMPANY of San Francisco, Cal., has issued the tenth edition of its 'Manual of Modern Surveying Instruments and Their Uses,' together with a catalogue and price list of the scientific instruments made by the company. The Lietz instruments are well known to the profession, having been made under the personal supervision of Mr. Lietz since 1882. They include the engineers' transit or theodolite, the Y-level, and the dumpy level; aluminum is largely used in the manufacture of these instruments. The manual also contains seven professional papers including 'A Short and Practical Treatise on Stadia Surveying or Trachymetry'; 'Remarks on the Principle of the Logarithmic Slide Scale'; 'Some Practical Hints on How to Tell a Good Surveying Instrument'; 'A Short and Practical Method to Find the Length of One Minute of Longitude in Any Latitude, Based Upon Certain Developments of the Terrestrial Spheroid'; 'The Cyclotomic Transit.' In short, this publication is not a mere catalogue, but contains much information of practical value to the engineer.

ROYAL SCHOOL OF MINES.—The annual dinner of the past students in the Royal School of Mines will be held at the Hotel Cecil, London, on March 18, at 7 o'clock. The chair will be taken by Mr. Richard Pearce, Ph. D., Past President of the American Institute of Mining Engineers. Tickets can be obtained from the honorary secretary, Mr. George T. Holloway, 57 Chancery Lande, London W. C.

Editorial.

IN 1907, 5000 railway passengers and employees were killed and 6330 other persons, mainly trespassers on the right of way, were also killed, that is, a total of over 30 per day. In addition 76,286 were injured on our railroads in that one year. The waste of human life is more appalling than that of warfare; in the latter it is intentional, in the former it is due to bungling among the managers and lack of discipline among the employees.

READERS of this journal will be doing us a useful service if they will send photographic prints or 'kodaks' of scenes illustrating mines and mining operations in their vicinity, such as we have published recently in conjunction with the correspondence from Nevada appearing under 'General Mining News.' These little pictures are valuable in suggesting the general appearance and progressive development of our mining districts. The photographs should preferably be printed on glossy paper, for the dull artistic print makes a poor copper halftone.

PRICES OF METALS are higher at the present time than they were in the industrial depression that followed the panic of 1893. In February, 1894, the average price of copper was 9.6 cents; lead was 3.31; zinc, 3.85 per pound; and silver stood at 63 cents per ounce. Today they are 13½, 3.75, 4.80, and 57½, respectively. Only silver is lower than in 1894; copper is 40% higher. But wages and supplies of every kind are much higher, we have all profited so much by the rise that relatively we feel the fall all the more, for our standard of living, whether in the home, or the shop, in the mine or the smelter, has reached the mark of extravagance. It costs 20 to 25 per cent more to extract the metals from the ground and it takes 20 to 25 per cent more for the miner and smelter to pay their bills than 14 years ago. The more we remember, the less we forget.

NEWS of the doings of professional men is always interesting to their fellow practitioners; hence the column devoted to 'personals' is widely read. In this issue we announce the retirement of Mr. H. C. Hoover from the firm of Bewick, Moreing & Company. This has been rendered necessary as much by the need of rest as differences of opinion. Mr. Hoover has been a tremendously active man for the last ten years and we are glad to think that he will not sacrifice his youthful manhood to the relentless pursuit of wealth. It will interest our readers to learn that in the 30 years previous to 1902, the largest number of working mining concerns associ-

ated with the firm of Bewick, Moreing & Company was 15. These were, in 1901, handling about 500,000 tons of various stuff and earning a profit of about £500,000. In 1907 the business had grown so as to include 45 concerns, handling 3,250,000 tons, earning about £1,600,000. These facts afford testimony to the industry and ability of the firm, and, we believe, especially to such qualities on the part of our friend, Mr. Hoover. We hope his holiday will bring him to California, for he is a graduate of Stanford University and one of the many engineers to whom this State has proved a real school of mines.

National Mining Bureau.

ON ANOTHER PAGE we give the text of a resolution introduced before the Congress of the United States in relation to the plan of establishing a mining bureau at Washington. The Committee on Mines and Mining has reported favorably on the proposal to create a branch of mining technology in the Geological Survey, but it has not yet endorsed the bill to establish a Bureau of Mining Technology in the Department of the Interior, separate from the Survey bureau. Senator Heyburn's bill expressed the desires of the Western men who have been agitating for a mining department for many years, but the radical legislation therein demanded did not find favor with the Committee on Mines and Mining. Senator Dick's resolution obtained the support of the friends of the Survey, mainly on the argument of Mr. Tillman, that it could be easily passed by the Congress, while the establishment of a separate bureau would require a hard fight. The sentiment of the Committee was unanimous that the proposed Division of Mining Technology in the Survey was to be regarded merely as a first step toward an independent bureau, but they were not then ready to endorse the recommendations of the Secretary of the Interior. We deem it proper to state that the officers of the Geological Survey are not to be blamed for the outcome, disappointing as it is. The director, Mr. George Otis Smith, has stated frankly that he favors "an increase in the mining work by the Federal government without duplicating that already authorized." As a matter of fact, the sentiment of the Survey people is for the Dick bill, which, on account of its brevity, offers fewer points for attack than the bill introduced by Mr. Englebright, as published in the MINING AND SCIENTIFIC PRESS of January 18. It is best to make the general law brief and simple, and to have it deal with principles only. Adequate protection against a wrong interpretation lies in the necessity each year of getting specific appropriations for carrying out the work. There is much good sentiment at the back of this movement for a bureau, especially as it relates to the investigation of mining accidents, and it is hoped that the Dick bill will be passed. The resolution introduced by the same senator is practically an endorsement of the work already undertaken by the Survey, which has wandered far from the field of activity for which it is best fitted, however excellent the motive prompting such departures. We hope most sincerely that the agitation for a National Mining Bureau will not end simply in legalizing the non-geological labors of the officers of the Survey, enlarging the bureau of geology so as to include subjects quite outside the special training of a geologist. The service to be done by a Bureau of Mining may be uncertain, the excellence of the geological investigations made by the Survey has been demonstrated beyond argument; let us not graft a new branch on a fruitful tree.

The Lead Market.

WE LEARN FROM AUSTRALIA that the idea prevails there that the lead market in San Francisco is badly congested. This is far from being the case. The Selby smelter, which is the controlling factor in regulating prices on the Pacific Coast, has only eight or nine hundred tons of 45 per cent concentrate on hand and is barely able to supply local needs. Early in January a shipment of lead amounting to 1500 tons was made to New York and that pretty well depleted the stock on hand. On the contrary, the chief depressing factor at the present time is the accumulation of lead concentrate at Port Pirie, in South Australia. We are informed that this stock, from the Broken Hill mines, amounts to about 50,000 tons. The concentrate was purchased by the European ore-buyers when lead stood at about £22 per ton (4.75 cents per pound); and the total accumulation, including zinc concentrate, amounts to 70,000 tons. The Australian situation is critical, for the ore-buyers will not take lead concentrate on the old terms, namely, for from 6 to 12 months, and at a charge of from 80 to 90 shillings, but they insist on contracts for a period of 5 years and a rate, including all deductions, of about £5½. Apparently, the buyers are unwilling to accept any more lead, even on their own terms, until the existing surplus has been consumed. Large sums of money must have been lost by some of the contracts made by metal merchants: for instance, in one or two cases at Broken Hill, a long contract was made on a charge of 82 shillings; this contract is still in effect and it was in effect when lead sold at about £14 per ton; in the interim the metal went to £22, and is now back to £14 again, so that several firms lost heavily by these transactions; it is not strange that they are extremely cautious now. On the other hand it is hard on the Broken Hill mine operators to have to pay an increased charge of about 30 shillings, or $7.50, per ton. But that is the experience on this side of the equator also. It is the old question as to who is to bear the loss due to falling prices; obviously it should be shared by the producer, the consumer, and the middleman. Of course, part of the trouble at Broken Hill, as elsewhere, in so far as concerns lessened profits from lead mining, is due to the advance in wages. At Broken Hill the increase amounts to 12½ per cent and even this figure does not give the full measure of extra cost to the producer, for besides the higher rate the operator faces diminished efficiency. In times of intense industrial activity when workmen are scarce

and unions exacting, not only are wages higher but poor workmen cannot be dismissed advantageously, for they are likely to be replaced by others that are no better. The men know that they are in demand and they abuse their advantage. Then comes a time of reaction; wages fall; men are idle; and the whole clumsy arrangement is re-adjusted. During the boom, the employee has the upper hand; when the depression arrives, the employer is the arbiter. It is a pity; apparently it is an essential part of a brutal cosmic process that the interests of the two sides should be antagonistic and they will remain so until a higher order of intelligence directs the actions of both the elements involved in our complex industrial civilization.

A Professional Blue Book.

SEVERAL of our professional friends have received a letter from Mr. H. M. Chance, of Philadelphia, inviting them to join him in the formation of a Mining and Metallurgical Association, the aim of which is to "promote and maintain the dignity and advance the interests of these professions by all means, and to perform functions covered by neither the American Mining Congress nor the American Institute of Mining Engineers."

It is fair to state that Dr. Chance is an engineer in excellent standing, an old assistant of Lesley, and a gentleman quite warranted in taking a lead in such matters. Next, we may quote from his letter a paragraph outlining the nature of the work to be performed by this Association; he says: "As one of the objects sought to be attained is the protection of the public and of the profession, by such measures as may be practicable, from the damage done both by charlatans posing as engineers and experts, it is proposed that the first work undertaken by the Association shall be the compilation of a directory, or Blue Book, of those legitimately engaged in mining, metallurgy, and allied industries and occupations, including all those, whether technically educated or not, who by experience may be qualified to render useful service in any particular class of work. It is proposed to insist upon rigid classification, precisely defining the character of services each is best qualified to perform, as indicated by the provisional list herewith enclosed, thus providing a means of discriminating between those who are and those who are not qualified to render useful service in these pursuits." Further on, he explains that "the responsibility for the exclusion of names from this directory will be assumed by a Board of Censors, elected by the Association."

Thus at last we shall know who is a mining engineer in good standing and the public will be told, by process of elimination, whom not to engage professionally. Speaking seriously, we have no hope that such a purpose can be accomplished; there is no probability that any group of men however representative could, or would, exercise judicial functions, separating the sheep from the goats, the respectable engineers from the charlatans or the has-beens, any more than the Mining Congress or the Institute. In the first place, some of the leading men in the profession would have to be excluded as being promoters who use the services of mining engineers rather than doing the work themselves. So also there are those who were once metallurgists and are now manufacturers and financiers; such men are no longer metallurgists. A clergyman who has unfrocked himself voluntarily, to become a stock-broker, ceases to be a priest; a man who formerly designed houses and who has retired to a farm is no longer to be rated as an active member of the profession of architects. Secondly, men are not fixed quantities; one who is sufficiently trustworthy and careful today to be in the Blue Book, may be guilty of the worst errors five years hence, through the undermining of his character by drink or greed; a poor fellow who erred yesterday and is today deemed unfit for a responsible position—or to be in the Blue Book—may pull himself together so as to be a first-rate engineer ten years hence. Let any man of twenty years' experience look over his acquaintances and he will be able to give names to fit the above descriptions. In a field of activity that is world-wide and amid the extraordinary changes of environment that befall the members of our profession, the ups and downs of moral assessment are tremendous. No Board of Censors could keep in proper touch with the fluctuating value of the human integer, for to no such body of men would all the necessary information be available. Take a practical example: We have 'Who's Who in America.' This is a 'blue-book' of men of standing and it is one of the best of its kind, but any familiarity with the contents of this directory of notabilities soon dissipates the idea that it is more than a useful volume of reference so far as it goes. No one would claim that it affords a complete list of the leading men of America today, for, to mention only one feature, it is predominantly filled with the biographical accounts of professors and writers, in fact, the sort of people that occupy an official position in the community by teaching or those that obtain a varying kind of prominence by writing; and all these people put together would not begin to represent the sum of American professional, financial, or industrial talent. In fact, this imitation at long distance of a Burke's Peerage is, in a democracy, bound to be a little ridiculous. You can rate men by rank in countries where a College of Heralds occupies itself with sifting the data necessary for the purpose; you can decide whether a man is of baronial birth or not, if you have his pedigree, because the question of his personal character or ability does not come into the question. But when you start out to decide the relative worth, professional attainments, or business fitness of the individual, you usurp a function that only omniscience can properly perform. We hope, therefore, that Dr. Chance and his friends will abandon the more ambitious feature of their undertaking and be content to publish a directory of those professionally engaged in mining and metallurgy, leaving the final appraisal of worthiness to that high tribunal to which a man is called when the last order comes, 'Lights out.'

Personal.

COURTENAY DE KALB is here from Los Angeles.

WILLIAM DE L. BENEDICT is here from New York.

JAMES C. SPERRY is in San Francisco for a few days.

E. GYBBON SPILSBURY sailed for London on February 4.

H. KILBURN SCOTT has returned to London from India.

SIDNEY E. BRETHERTON, of Redding, has gone to New York.

PHILIP L. FOSTER was recently in London, from New York.

F. W. OLDFIELD is examining prospects at Rawhide, Nevada.

J. W. MERCER has returned from Ecuador, and is now at Denver.

ROBERT M. RAYMOND is returning from London to El Oro, Mexico.

HERBERT HAAS, of the Union Iron Works, has gone to Goldfield, Nevada.

ERNEST LEVY is temporary manager of the Le Roi No. 2 at Rossland, B. C.

SEELEY W. MUDD returned recently from a trip to Europe. He is now at New York.

OTTO SUSSMANN returned to Salt Lake last week from examining mines in Idaho.

GEORGE MOORE of the Moore Filter Co., New York, was in Salt Lake City last week.

JAMES W. LONG, formerly at Ouray, and lately in Nevada, is on a visit to San Francisco.

H. D. PALLESTER, of Terlingua, Texas, is visiting the quicksilver mines of California.

SCOTT TURNER has gone to Tacoma, to superintend sampling operations at the smelter.

W. J. PENTLAND is general manager for the Campañia Minera, Juarez, in Sonora, Mexico.

JOHN L. HENRY, of Oakland, has gone to northern Mexico, to examine a group of gold mines.

JOHN A. REID sails on the *Curaçao*, leaving on February 15, for Triunfo, in Lower California.

J. E. SPURR and W. ROWLAND COX have formed a partnership, with offices at New York and Denver.

J. H. VAN DENBERGE, whose office is at 74 Broadway, New York, is now examining mines in Colorado.

LLEWELLYN HUMPHREYS is consulting engineer for the Gunn Thompson Co., operating at Ely, Nevada.

EDGAR NEWHOUSE, of the American Smelting & Refining Co., is in San Francisco, on a tour of inspection.

CHARLES A. SHELBY is superintendent of reduction division for the Cananea Consolidated Copper Co., in Sonora Mexico.

R. C. SHAW was very ill in Costa Rica and had to return invallded. He is now recuperating his health in South Carolina.

W. A. REED, formerly with Liberty Bell Co., at Telluride, is manager of the W. P. H. Leasing Co. at Cripple Creek, Colorado.

JOHN HAYS HAMMOND underwent an operation for appendicitis in San Francisco on February 12, and is recovering satisfactorily.

Owing to ill health brought on by overwork, H. C. HOOVER is retiring from active partnership in Messrs. Bewick, Moreing & Co., and W. J. LORING takes his place as technical head of the firm. Mr. Hoover is retained by the firm for general advice and at the request of the boards of directors of various companies retains his seat as a director.

ROYAL SCHOOL OF MINES.—The annual dinner of the past students in the Royal School of Mines will be held at the Hotel Cecil, London, on March 18, at 7 o'clock. The chair will be taken by Mr. Richard Pearce, Ph.D., Past President of the American Institute of Mining Engineers. Tickets can be obtained from the honorary secretary, Mr. George T. Holloway, 57 Chancery Lane, London W. C.

Obituary.

FRANCIS T. FREELAND died at Philadelphia on January 27. He was staying at the Colonnade hotel and is supposed to have succumbed to apoplexy. He ranked high in the profession. Born at Philadelphia and a graduate from the University of Pennsylvania in 1879, he early developed skill as a mathematician. Going to Colorado, he became manager for the Iron Silver Mining Co. at Leadville, then he was successfully engaged at Aspen, and still later he was manager of the Isabella mine at Cripple Creek. He contributed several important papers to the Transactions of the Institute, notably one on faulting, and was a leading expert in mining litigation. For the last five years he had practically retired from professional practice. He had just returned from a journey round the world when he died. He was never married, but had many friends.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Big Springs Mining Co. has 10 men stoping ore in a 165-ft. adit of the Claire mine; this ore is mostly of the silver-lead class, but in one place the lead is replaced by copper. All of the ore carries gold, several assays indicating 1 to 4 oz. per ton. Several smelter shipments show that the ore averages at least $30 per ton in lead, silver, and gold. C. W. McCoy is manager.——Supplies are being forwarded to the property of the Lutz Mines Co., in the Huachuca mountains; H. J. Amphlett is superintendent. ——The owners of the Savage mine are preparing to install a heavy hoisting plant, sink a new working shaft, and build a concentrating plant.——The Paradise Mining Co. is sinking a shaft which is to be 250 ft. deep.——At the King of Lead mine three men are working; they are making occasional small shipments of ore.——At the mine of the Bisbee-Sonora Mining Co., in the Paradise district, an adit has been driven 182 ft. to develop the Badger-Hail lode; it has cut the vein and the entire breast except a few inches in one corner is ore carrying silver, lead, and copper. The vein is over 60 ft. wide at the surface.

GILA COUNTY.

It is reported that the Keystone and Live Oak mines will pass into the possession of a New York syndicate.

GRAHAM COUNTY.

Rich gold ore has been found in the bottom of the shaft of the Old Gold Belt mine in the Clifton district.——Development work at the New York-Arizona property continues to reveal a fair grade of milling ore.——Walter Doudna, who has a bond on the Gypsy Queen and several other claims in the Greenelee district, has let a contract to W. S. Riley to drive a 75-ft. adit on the Gypsy Queen claim. ——E. Depee reports that he is mining excellent silver ore at the Harper mine near Morenci.——The Arizona Copper Co. has produced 1441 tons of bessemer copper during January; several new converters and a number of converter tops have arrived from the El Paso Foundry & Machine Co.——C. D. Cameron in developing the Celtic group of claims near Metcalf, has found sulphide ore, averaging 28% copper and carrying some gold and silver. A small pumping plant is to be installed.

MOHAVE COUNTY.

(Special Correspondence).—The Smith-Shaefer group of claims was sold last week for $65,000 cash to Kingman and Eastern parties; the sale was effected through W. O. Young of Salt Lake. The property is near Chloride.

Kingman, Feb. 7.

PINAL COUNTY.

Plans are being matured for the erection of a more extensive plant at the Sultana-Arizona mine; this is to include a power plant, tram, concentrator, compressor, and other machinery. A good force of men is employed doing extensive development work. The company has shipped 16 carloads of ore that carried, according to smelter returns, 10 to 20% copper. Several more carloads of ore are on the dump ready for shipment. John Mecham is president of the company.——T. H. Crowe purchased a stamp-mill and was preparing to erect it at Troy when the financial panic tied up his funds in the Globe National bank.—— The new smelting plant of the Southern Arizona Smelting Co. at Sasco, was blown in on Feb. 1 and is running satisfactorily. It is a thoroughly equipped plant, with at present one furnace of a daily capacity of 350 tons, but another furnace of equal size has been ordered. The smelter was built primarily for the reduction of the ore of the Imperial mine, 12 miles south of the smelter, but later will handle custom ores if they are offered.

YAVAPAI COUNTY.

The smelter company at Humboldt is settling local bills, including taxes, and preparing to start up.——The new perpendicular shaft at the Logan mine, 4 miles southeast of Skull Valley station, is 115 ft. deep; it exposes ore the leanest of which assays 3% copper and $1 gold per ton. The mine is opening a belt of sulphide-bearing schist whose outcrop is 250 ft. wide. Water is piped to the camp from a spring on one of the claims; a sufficient supply can be developed for a large reduction plant. W. J. Casey is foreman at the mine.——The Redmen Mining Co., whose property is near McCabe, has purchased a 5-stamp mill, air-compressor, and two power drills.——It is said that the Logos Mining Co., operating in the Bigbug district, has developed an orebody 26 in. wide, consisting of chalcocite ore carrying 20 to 40% copper.——A 12 hp. gasoline hoisting plant is to be erected at the Critic mine near Wendendale; this mine is being operated by Loftus & Davis.——C. B. Genung has uncovered a rich gold-bearing vein on his property near the Congress Junction road; it is exposed in a 40-ft. shaft that was dug years ago.——The Cardinal Mining Co. has sufficient ore in reserve in the Express mine for a long mill run; it is to be crushed at the mill of the Arizona M. & M. Co.——At the Mescal mine in the Jerome district two shifts of men are driving an adit and it is stated that another shift will be added as soon as practicable.——Work has been abandoned at the Boston Jerome mine until a power hoisting plant has been installed.—— At the Verde Grande mine the shaft is 510 ft. deep; sinking has been stopped for the purpose of cutting a station.—— The Haynes Copper Co. is installing the machinery necessary for the sinking of a shaft over 1200 ft. deep.

CALIFORNIA.

BUTTE COUNTY.

Blue ground was struck on Feb. 5 at a depth of 92 ft. in the drill-hole being sunk at the diamond mine. This blue ground was drilled into about 10 ft. and sufficient samples obtained to show that the formation is identical with that in the main shaft on the property. The drill will now be moved to another portion of the ground, as the object of the drilling is to determine the extent of the so-called 'kimberlite' deposit.

CALAVERAS COUNTY.

It is reported that the management of the Melones mine is seeking a crew of men who speak the English language. ——Sam Davidson found $160 worth of gold nuggets in the course of a day or two of panning on ground near the old Boston quartz mine. This ground was worked years ago by Frenchmen, but it now appears that there may be several acres of virgin ground.

EL DORADO COUNTY.

The preliminary work at the Bean Hill hydraulic mine is completed. The company has a fine debris dam. One of the Debris Commissioners examined several dams in the vicinity of the Bean Hill mine and selected sites for several more dams.——W. Dean and son are busily working their hydraulic mine.——It is proposed to begin work shortly at the Stillwaggon mine; W. L. Rees is to be superintendent.

INYO COUNTY.

A vein 2 ft. wide has been uncovered on the Poppy group of claims at Skidoo. The find has created excitement in the camp because a sample from half the width of the vein assayed $1568 per ton and a sample from the remainder assayed $261 per ton. Walter Wright, S. W. Cline, and J. Frank are the owners.——At the Skidoo company's property, the main shaft is 400 ft. deep and between 4000 and 5000 ft. of development work has been done, not counting lessee's operations. There have been developed three veins 1 to 3 ft. wide of relatively high-grade ore. One of them which is 2 to 2½ ft. thick has been exhaustively sampled and is said to carry $68 per ton. The construction of a mill is in progress.——Work is being pushed on the Yellow Garter group of claims and it is now thought that the Gold Standard lode has been found on it.——The final touches are being put on the Casa Diablo mill and on the repairing of some electric transformers that were unable to withstand a test. Development work in the mine has

exposed an orebody 40 ft. long and 28 in. wide; this ore is said to carry $100 per ton.——Samples from the 700-ft. adit of the Dunlap mine assayed $5.47 per ton; they were from the country rock and the vein has not yet been reached.——The erection of the new 30 stamp mill for the Snow Canyon company is proceeding rapidly.

NEVADA COUNTY.

Work at the Normandie mine is being pushed with vigor; the shaft has been unwatered and sinking has been begun. ——Owing to the financial state of the country only a few men are employed at the Norambagua mine; Richard White is superintendent.——The Greek lode has been cut in the cross-cut of the Union Hill mine; it is 2 ft. wide and contains free gold plainly visible. The same company has a shoot of high-grade ore in the Wiltsee vein.——The long drainage and transportation adit project known as the Twin City Subway is slowly making headway toward organization. The promoter, George Downey, has not met with any opposition of property holders on the route selected by him, and is receiving encouragement from the owners of the mines that will come within the sphere of benefit of the long adit.——At the Idaho Maryland mine 10 stamps are crushing ore from the 500-ft. level; the ore-shoot has now been opened for 100 ft. and it is 18 in. wide. ——Negotiations are in progress for the sale of the old Pittsburg quartz mine on the Gold Flat slope of the Banner Mountain ridge. This mine is developed by a shaft 1000 ft. deep; the lode varies from 6 in. to 4 ft. wide. Some of the ore carried from $50 to $350 in gold and silver per ton. The vein at the Brunswick mine is 18 in. wide; the company paid one dividend and made many improvements while working out a block 250 ft. high and 450 ft. long.

PLACER COUNTY.

At the Southern Cross mine all repairs have been made and things are ready for a good run. The 20-stamp mill will be started shortly and the crew of 12 men will be increased to about 25; James H. English is superintendent. ——M. Savage has a small force of men developing the Three Queens mine; he is opening an ore-shoot that years ago yielded $14,000 from a piece of ore the size of a parlor stove.——The Crater mine has been drained and everything is in readiness for driving on the 800-ft. level.—— Lee McCoy has struck a 'white channel' at the Vier mine on Georgia hill.——The Cash Rock dredge has been completed; the suction pipe can take up and throw off a boulder 9-in. diam. An oil-tank of 80,000-gal. capacity is being built on the river-bank.

PLUMAS COUNTY.

L. N. Tefft has several men employed in fitting up the Illinois placer claim near Cromberg; he also has the Lone Star and Concordia mines ready to run. The latter contains a body of gravel nearly 200 ft. deep; this is said to prospect fairly well from surface to bedrock.

SHASTA COUNTY.

The roadbed of the Sacramento Valley & Eastern railroad has been graded to Delamar and the rails will soon be laid. Freight for the Bully Hill mine and smelter is being hauled by wagon from Horse Creek station, only two miles from Delamar. March 1 has been fixed as the probable date for blowing in the remodeled and enlarged smelter at Delamar.——Since smelter construction ceased at Coram business has become so slack that the Southern Pacific Co. has closed its station at that point.——Fred Maxwell reports that he has found a good body of ore in the old workings of the Uncle Sam mine, near where the last lessees, Nicholas & Thomas, took out their ore.

SIERRA COUNTY.

A test run of 5100 lb. of ore from the Wyoming mine at Alleghany which was recently crushed in the Eldorado mill yielded by amalgamation $580.80; this is equivalent to $227.76 gold per ton of ore. In addition about 50 lb. of sulphides were saved on the concentrating table. A winze which is being sunk on the lode is 15 ft. deep; in the bottom the ore is 4 to 5 ft. wide. Stanley M. Welland is superintendent.——The Happy Jack lode is being developed under bond and lease by Frank McLaughlin; he is driving an adit on it.

SISKIYOU COUNTY.

The Adeline Ricks mill near Callahan is crushing about 50 tons of ore per day; Frank Zeigler is superintendent. ——The open winter season has been of great help to mining men in enabling them to haul in supplies to continue development work. Many mining companies that have formerly ceased operating during the severe months, this year have continued with unabated vigor.

TEHAMA COUNTY.

It is said that William Shader's big steam drilling plant has sunk one hole 118 ft. and another over 60 ft. on the ranch of J. W. Widner, the object being to test the claim of O. H. Stott that he has found by means of an apparatus (which he calls a plumb bob) that will be attracted by gold, a place under which there is gold. The drillers seem to have been more successful in finding water than gold.

TRINITY COUNTY.

Including lessees, about 25 men are mining ore at the Brown Bear properties. The mill will be started as soon

as the roads are in condition suitable for ore hauling.—— At the Lappin mine a small force of men is doing development work. In the spring the force is to be increased and the mill started. The owners intend to install an electrical equipment, connecting with the Northern California Power Co.'s line at the Brunswick mine.——C. A. Carter, the owner of the Hostetter gravel mine at Minersville, has two monitors set and everything in readiness for work; he is waiting for the water months, which in that section are usually March, April, and May.

TUOLUMNE COUNTY.

A cross-cut is being driven for the main adit of the Wallwood mine to cut the lode at greater depth than heretofore exposed.——The main adit of the Morgan mine at Carson Hill is being cleared of debris to admit a party of English experts to the underground workings to make an examination of the lode; the samples taken will be sent to England.——S. A. Ryland of the Angels Iron Works is in charge of the construction of the new Kanaka mill at Groveland.——The new tramway at the Cosmopolite mine has been completed; it is expected that now the mill can be kept in continuous operation.——Frank Webber, a junk dealer and trader of Stockton, has been arrested on the charge of having stolen two plates from the Bonanza quartz

mill in North Sonora. These plates, with the amalgam on them, were worth at least $500.

YUBA COUNTY.

The Weed's Point mine near Camptonville is being successfully operated; the long bedrock adit was completed some time ago. The gravel is said to be profitable to mine. Two good restraining barriers impound the debris. C. L. Crane is manager.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The new 50-ton mill of the Empire Tunnel Co. was put into commission the middle of last week. The machinery consists of two gyratory Hatheway mills and occupies very little space on the floor; from the test runs of the same a saving of 94% of the gold was effected. The process includes fine-grinding, reducing to 200 mesh. In this manner the gold is released from its coating; by a spray of water shooting up from below, the gold and rock are lifted, the gold dropping first, where it is gathered up by quicksilver. It is then transferred to the bullion box, which at all times is kept securely locked; in time it is retorted and disposed of at the U. S. mint. If the mill will do one-half the work that is claimed for it, a new era will dawn for the sulphide belt of upper Clear Creek. It will result in scores upon scores of low-grade mines being placed upon a paying basis, as throughout the Empire section enormous bodies of ore are showing which could not formerly be handled at a profit. The people of this district are anxiously awaiting the final results, as no time will be lost in placing orders for mills. The Empire mill is being fed upon ore found in the Gold Dirt mine, and from the test runs it has been ascertained that the material can be mined and milled at a cost of not over 75c. per ton.——The Capital mill is now running steadily and it is reported that a high saving is being effected. The machinery is being run on ore taken from the east and west drifts on the Aetna vein. Over 1000 tons of this material are in reserve, while the mill-bins are filled to the top. Manager W. M. Cooper is adding to the working force and will have between 100 and 150 men at work inside of 30 days.——Shipments from the Columbia mine on Silver mountain were started this week by the lessee, John Graham. Stoping is in progress upon a streak of gold-bearing ore that is from 18 in. to 2 ft. wide, the average value of which is $39 per ton.——L. Baccheirl has taken a lease upon the Wide West mine on Leavenworth mountain. A force of 10 men has been put to work in cleaning out the workings, and shipments of both high and medium-grade ore will be inaugurated inside of the next 30 days. This mine has a record of having surrendered in excess of $1,000,000, and the ground has not been worked to a depth exceeding 600 ft. It is surrounded by such famous producers as the Colorado Central, Allunde, Kirtley, and Equator, the combined output of which is in the neighborhood of $20,000,000.——The Miller adit on Saxon mountain is being driven steadily forward, having now been advanced for 450 ft. According to surveys a vein will be reached within from 40 to 50 ft.——Operations were put under way this week upon the Panama group of five claims, situated on Columbia mountain. The adit, in 125 ft., is being advanced to intersect a vein that lies 20 ft. distant. Considerable scattered ore running through an 8-in. streak of quartz is showing in the heading. E. E. Grubb & Co., are operating under lease.——H. W. Kirby & Co., who own the Bernhardt group of claims on Green Lake mountain, are employing a force of men in driving the adit for the intersection of the veins. One lode was recently cut, and while a big body of mineralized quartz is showing, no drifting has been performed.——J. F. Allinde, leasing at the Santiago mine, has uncovered a 2-ft. streak of ore that shows by assay 14% copper and 3 oz. gold per ton. A total of 40 tons was run over the aerial tramway last week. ——Wood & Co., leasing on the 14th level of the Terrible mine, have 60 tons of smelting ore ready for shipment; this will mill on an average $50 per ton in silver and lead. In addition to this, over 200 tons of concentrating ore have been placed in the mill-bins; it will receive treatment as soon as there is sufficient water flowing through the pipeline to permit of operating the machinery. Large development on company time is promised for the near future. ——The New Boston mine on Democrat mountain has been bonded and leased to McKarahan & Parks, the bond calling for $35,000. These operators have secured the use of the aerial tramway owned by the Democrat Mt. M. Co., as well as the privilege of treating the ore at that company's mill, which has a capacity of 50 tons daily. The concentrating material is a lead-zinc ore, while the smelting ore brings returns of 40 oz. silver per ton and 60% in lead.——The Dunkirk mine, a famous old producer of Sherman mountain, is again undergoing development in an energetic manner. This property recently passed over to a syndicate of Denver capitalists, headed by M. D. Smith of Georgetown. The raise from the Ashby adit is being placed in condition and levels are to be run from each 100-ft. station. Large streaks of good-grade ore are showing in many of the workings, and shipments are promised for the near future.——Active development is under way at the Collins property on Leavenworth mountain. The adit is being driven to intersect the vein at a depth of 150 ft. under the shaft workings. In the bottom of the shaft a streak of ore is showing which is 8 in. thick, the average value of which is $50 per ton in silver and lead.—— Work has been resumed in the driving of the Bi-Metallic adit, which is now in 1000 ft. The first vein to be reached is the Blue Bell; this produced much high-grade ore a number of years ago. John W. Boughton of Silver Plume is general manager.

Georgetown, Feb. 1.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The resumption of the Cherokee Lanyon smelters at Gas City and Coffeyville, one-half of the Ozark Oxide Co.'s plant at Coffeyville, together with two additional blocks of furnaces at the Lanyon-Starr smelters at Bartlesville, added strength to the demand for zinc ores during the first week of February. However, the increase in production fully met the demand and there was no advance in price. For the week ending Feb. 1 the shipment of zinc ore fell 800 tons below that of the previous week, owing to the operators holding for higher prices. Lead shipments were 188 tons greater and brought from $48 to $50.50 per ton for the 80% grades.——The rejuvenation and extension of the Carl Junction camp the past few months have been among the important developments in the Missouri-Kansas field. When the old Lehigh mines were active some years ago prospecting was prevalent all over the camp, but no free orebodies of importance were discovered, although a number of strikes of low-grade sheet-ground were made. Interest in that camp flagged until the development and successful exploitation of sheet-ground in the Webb City camp proved to operators the value of such deposits. Since then operations have been resumed in Carl Junction, and an important addition to the mining district is now being developed. The Kramer Mining Co. has undertaken the development of 400 acres of land surrounding the camp. A large part of this has been drilled and a peculiar sheet-ore formation discovered on lands lying north and west of the town. This ore is a finely disseminated blende in a matrix of silicious mud-rock. The rock is apparently a sediment resulting from the degradation of the carbonaceous shales of the Pennsylvanan rocks, highly silicified. The intimate mixture of the blende with it presents a problem in milling which necessitates extremely fine crushing and table concentration to recover the blende. The extent of the orebody has been shown by drilling to be very large, underlying over 200 acres of land, and the drilling is not yet completed. On the lease north of the city shafts were put down, but water proved a hard problem below the 180-ft. level. A pumping plant with a capacity of 5000 gal. per min. was installed before the orebody could be reached and opened up. The heaviest deposits of ore occurred at 225 ft. After

thoroughly developing the deposit and testing the ores, a concentrating plant was designed to treat them. While modeled after the regular type of Joplin mill, it is designed to slime all the chats, the proportion of cleaned concentrate being greater from the table concentrators than from the jigs. The capacity of the mill is 400 tons per 10-hr. shift. The mill began operations this week and there are 10,000 tons of ore on the dump awaiting treatment. The experiment of treating this peculiar sheet-ore is being watched with interest, and if successful will inaugurate the development of large tracts of adjoining lands. West of the city this same company has sunk a shaft and the orebody has just been penetrated. The deposit is sheet-ore but free from the features found in the deposit on the north lease. A concentrating plant will be erected at this shaft during the early spring. W. C. Kramer is manager of the company's field operations.——The developments to the south have been as important as those noted north and west. The land of the Avondale Mining Co. has been actively prospected and the operations have resulted in a wide area of proved ground. On the west 80 acres, the Jubilee Mining Co. has a sub-lease and has put down 25 drill-holes. A number of workable orebodies have been demonstrated. This company is now sinking a shaft on the east side of the tract and a sub-lease was given to the Lehigh Zinc Mining Co. on 12 lots, on the west side. Upon this sub-lease a body of sheet-ore has been opened and a 150-ton mill will be erected. Two other sub-leases have been developed sufficiently to reach the ore, but the extent of the deposits has not been determined.——The sub-lease held by the Carl Junction Mining Co. has reached a producing stage. On a six-lot lease an orebody 150 ft. long, 145 ft. wide, and from 15 to 20 ft. thick has been developed at the 100-ft. level. The full extent of the orebody is not yet known as the headings are still in ore. A 125-ton concentrating plant has been erected and began operations last week. The ore is exceptionally free and runs at times as high as 30% zinc. The discoveries of new bodies of sheet-ore and the development of these free-ore deposits have started a new movement of prospecting throughout the Carl Junction camp. The importance of this development is noted in the large increase in the production of this camp in 1907 over that in 1906.——The drilling recently undertaken by L. P. Benua of Carthage on the old Porter mining tract in the northwest portion of that city has resulted in the discovery of a rich deposit of blende. The ore was first encountered at 35 ft. and continued in open ground to 111 ft., where the drill entered a deposit of chert and blende extending to 167 ft. This tract was once famous as a producer from the shallow levels but had been abandoned for years, no attention having been given to the lower levels. The recent discovery has given a new lease of productivity to a tract of at least 60 acres.

Joplin, Feb. 5.

NEVADA.

CHURCHILL COUNTY.

Formal transfer of stock representing the control of the Fairview Eagle's Nest Mining Co. was made on Feb. 5 to O. P. Posey. This property was one of the assets of the Sullivan Trust Co. which failed with liabilities amounting to $1,200,000.——An old-time stampede out of Fairview, Fallon, and Rawhide occurred on the night of Feb. 5, when the people of these towns got word that a strike of exceedingly rich gold ore had been made by Archie Graham in the range back of Sand Springs; samples taken at the property assayed from $1700 to $2100 per ton, principally gold.

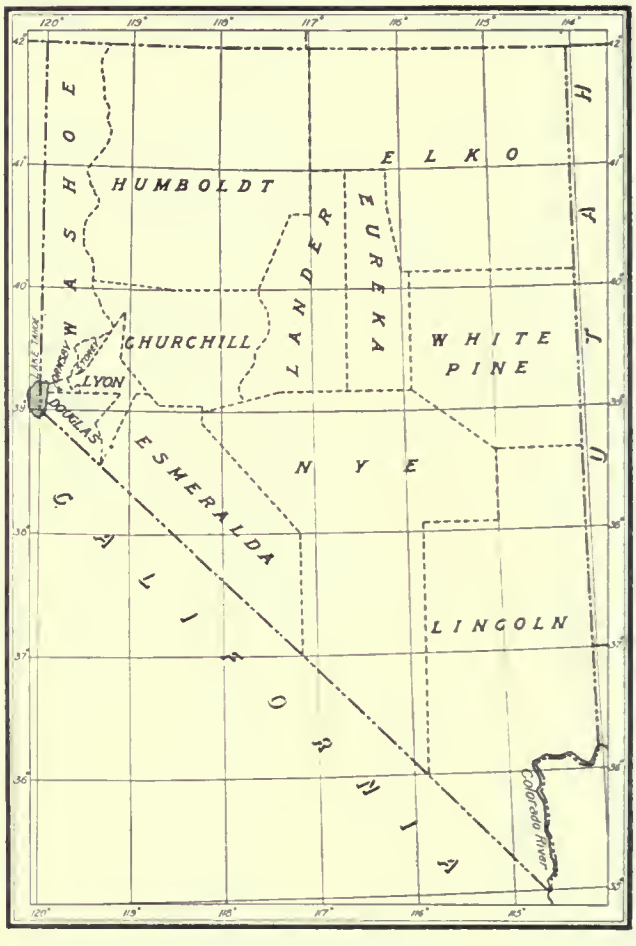
ELKO COUNTY.

Blewett Bros. are working two shifts at the Jack Pot mine at Aura; they have cut the lode in the lower adit. ——The owners of the Big Four mine are steadily driving No. 2 adit; a sample from the ore sacked has assayed $162.31 gold and silver per ton. The vein averages 3 ft. 10 in. wide.——Theo. Storff is operating his placer mine in the valley of Sheridan creek; this valley has some of the best placer ground in the Aura district.——The business men of Battle Mountain are planning to construct a railroad to Gold Circle.

ESMERALDA COUNTY.

President Roosevelt has telegraphed to Governor Sparks that the troops will be withdrawn from Goldfield on March 7. It is expected that by that date the organization and equipment of the State police will have been completed. The Governor has appointed Captain W. L. Cox superintendent and A. W. Cahlan inspector of police. As soon as equipments have arrived from the Eastern States 30 members of the newly appointed police will be sent to Goldfield, where they will be drilled. It is said that the cost of living in Goldfield has been greatly reduced; the miner who receives $4 per day now can purchase much more for this sum than he could for $5 a few months ago. This condition strongly supports the position of the Goldfield Mine Operators' Association in its change in the scale of wages for work performed in and about the mines.

Although at least 2000 miners were out of work on account of the strike, and many heavy producing properties were closed down, the January production of the Goldfield district was valued at $427,807.50; the Combination mill crushed daily 85 tons of ore, of an average value of $62.50 per ton, or a total of $164,687.50; a small run of ore from Goldfield Consolidated properties that was treated at the Kinkead yielded $5000; the Western Ore Purchasing Co. received 358 tons, of a total value of $32,220; 400 tons of ore from the Combination Fraction, Mohawk-Jumbo, Sandstorm, and Great Western mines, treated at the Nevada-Goldfield Reduction Works, yielded $38,000; and 947 tons shipped to the smelters produced $187,900.——While practically no production is being made by the properties of the Goldfield Consolidated company, with the exception of sufficient ore to keep the Combination mill running, they are being actively developed. The mines are being manned by non-union miners and by members of the new organization, the Nevada Miners' Union No. 1. It is said that all the help needed by the company is obtainable and that three shifts are employed.——The superintendent of the Nevada-California Power Co. has been looking over the



The Counties of Nevada.

ground with a view to extending a branch line into the Stimler district.——The main shaft of the Murray lease at Rawhide when 43 ft. deep is said to have exposed rich ore. Grab sampling from the ore that was being hoisted at that time indicated that it carried about $100 per ton.

LANDER COUNTY.

(Special Correspondence).—The Western Mines Development Co., of which J. D. Hubbard is president, has acquired the Hidden Treasure group in Mill canyon, 30 miles south of Beowaive station, and has consolidated it with an adjoining property which had been acquired by V. P. Strange of Salt Lake. Gold ore of milling grade has been uncovered and a force of 10 men is at work, under the direction of Mr. Strange.——Major Gillette of Philadelphia has taken over the Little Gem group of claims owned by the Reliance Mining Co., near Tenabo. This is to be consolidated with adjoining property and further development is to be prosecuted on the exposed orebody. The intention is to erect a mill.

Beowaive, Feb. 7.

LYON COUNTY.

It is reported that about Feb. 9, A. H. Gale and J. R. Thompson, former railroad laborers, after being lost for 24 hr. in a storm in the Wild Horse mining district, 12 miles south of Hazen, found a 3-in. vein of high-grade gold ore. This was reported throughout the country near Hazen and many of the residents of that town and 200 of the men employed on the Government reclamation project have deserted their work to rush to the scene of the strike.

NYE COUNTY.

(Special Correspondence).—The development of properties in the camp is proceeding in a fairly active manner, considering the condition of the money market and the strain upon all interests in this section of Nevada for the last three or four months. Frank Peterson and associates, of New York, have bought out all interests in the Manhattan Ore Reduction & Refining Co., which includes the holdings of E. B. Cushman and J. H. G. Wolf, as well as the mining companies interested in the enterprise, for which Peterson and associates have paid something over $75,000, and on which they will spend an additional $10,000 to increase the power, so as to treat 40 tons of ore per day. The plant is a 10-stamp battery, with classifiers, tube-mill, Butters filter plant, 40 frames, and zinc precipitation press, of the Merrill type, using zinc dust as precipitant. Mr. Peterson and his associates have also taken a five-year lease on three of the promising properties on Gold Hill, namely, the Stray Dog, Jumping Jack, and the Indian Camp, and expect to develop these properties sufficiently in the next six months to produce ore regularly for the mill. Meanwhile the milling plant will run on a contract made with the Manhattan Consolidated Co. for the reduction of its ore.

Manhattan, Feb. 7.

The ore shipments over the Tonopah & Goldfield railroad for the week ending Feb. 6, as reported by the Western Ore Purchasing Co., consisted of 88 tons from the Tonopah Extension and 80 tons from the MacNamara mine. The Tonopah company sent 3100, the Belmont company 940, the Jim Butler 167, and the Montana-Tonopah 1100 tons to the mills. The total output of the Tonopah mines was 5475 tons, of an estimated value (the shipping ore being valued at $60 per ton and the milling ore at $20 per ton) of $116,220.——At the Belmont mine two more veins to the south of the South vein have been cut on the 8th level; the first vein is 8 in. wide and carries $125 per ton, the second vein is 12 in. wide, but the ore has not yet been assayed. A. H. Jones has been appointed superintendent of the mill.——Two carloads of ore aggregating 100 tons, of an estimated value of $125 per ton, were recently shipped from the MacNamara mine.——At the Tonopah Extension mine, driving on the 1050-ft. level, below the dacite, is said to have cut many large stringers that indicate proximity to a large orebody.——About 135 men are employed by the Montana-Tonopah Co.——The material for the cyanide plant at the Bullfrog Pioneer mine has been delayed by stormy weather. A Balke crusher has been purchased. The ore in the drifts on the 110-ft. level assays $10 per ton.——The pipe supply at the Gold Bar stamp-mill was not strong enough to stand the pressure and burst at the first test.——The new owners of the Montgomery-Shoshone Extension property are preparing to install a compressor and sink the shaft from the 300 to the 500-ft. level.——On the Denver vein of the Tramp Consolidated property good ore has been found; Charles N. Carding has succeeded W. D. Blackmer as manager.——The Montgomery-Shoshone company continues to ship a carload of high-grade ore per day to the smelter.——The main shaft of the Crœsus mine is 360 ft. deep; sinking will be continued.——On the 400-ft. level of the Mayflower Consolidated mine, a vein 22 ft. wide has been cut; it consists of good-grade free-milling ore.

STOREY COUNTY.

More men are now employed in the mines at Virginia City than for several years. The recent uncovering of a new body of rich ore in the Ophir mine has given further encouragement to other companies that have been doing development work; 120 men are employed by the Ophir company.——In the Yellow Jacket mine 40 more miners were placed at work on Feb. 5.——The New York-Nevada company is at present operating the Underground mine.

WHITE PINE COUNTY.

The Black Horse Central Mining Co. intends to erect a custom mill at Black Horse; it is to have 20 stamps, four Frue vanners, four Wilfley tables, and a cyanide plant. A. G. Burritt is president of the company.——It is expected that as soon as the snow melts there will be a wild rush into the Steptoe district; the Vulcan mine of the district already producing shipping ore.——At the Siegel mine 15 men have been doing development work during the winter and the property now has in reserve and on the dumps several hundred tons of high-grade silver-manganese-iron ore; for years every smelting company near Salt Lake to which this ore has been shipped, has paid the Siegel company a premium above its assay value.

UTAH.

JUAB COUNTY.

(Special Correspondence).—The Tintic Smelting Co., controlled by Jesse Knight of Provo and managed by W. L. Mangum, is making good progress on the construction of its smelting plant, situated between Eureka and Silver City. By next May it is estimated that the plant will be ready for business. It will start with two 46 by 162-in. lead furnaces and two hand roasters for roasting the sulphide ores; each is 14 ft. by 60 ft. 1 in. The plant will also be provided with a 300-ton sampling mill, a briquetting machine and a bullion melting room for dressing the bullion. It is being constructed under direction of Howard P. Saunders as consulting mechanical engineer. It is stated that Richard F. McCaffrey of Salt Lake is to be superintendent and metallurgist when the plant begins operating. The mines being operated by Mr. Knight and associates include the Colorado, Black Jack, May Day, Beck Tunnel, Iron Blossom, and others.

Tintic, Feb. 7.

CANADA.

BRITISH COLUMBIA.

The ore shipments from the British Columbia districts for the week ending Feb. 1 were as follows: Boundary, 22,011 tons; Rossland, 5915; East of Columbia River, 3052; total, 31,008 tons. The receipts at the smelters were as follows: Grand Forks, 22,011 tons; Trail, 6011; Northport, 1240; Marysville, 675; total, 29,937 tons.——Despite the somewhat discouraging price of lead, shipping has been going on freely from the Slocan district.——Arrangements have been made for the immediate installation of extensive mining machinery at the Little Bertha mine at Bannock City.——Contractors are engaged in sinking a shaft at the Handy Group mine, which is situated at the junction of Lynch creek and the Lardo river.——Louis Pratt and J. A. Whittier have taken a lease and bond on the Province group of claims.——Good ore has been found in a 52-ft. adit on the Peacock group of claims in the Nicola district.

Special Correspondence.

LONDON.

Gold Mining in Tasmania.—The Diamond Market.—Champ D'Or.—Coal in Natal.—Deep Mining at Kalgoorlie.—Mr. Landau's Lament.

The Tasmania Gold Mining Co. is still unable to record a profit. The company was formed in 1903 by John Taylor & Sons to acquire a number of properties in the Beaconsfield district of Tasmania. These properties had been worked by various owners for many years, and with good results, but unfortunately operations had to be suspended owing to the workings arriving at the water-level, below which it was impossible for anybody but a millionaire to sink. The workings appeared to form a channel for the drainage of the surrounding country. When John Taylor & Sons took up the business the first thing to be done was to provide pumping engines of great capacity, made by Hathorn Davey & Co. of Leeds. During the erection of this machinery, the elements gave further evidence of what they can do in the way of flooding, and a great deal of damage was done to the mine and to the plant. However, during most of this time the production of gold went on, and during the three years ended September 30 last the output has been steady at about £130,000 per annum. The current expenditure on ordinary operations, and the special expenditure on flood protection have more than wiped out any profit so far. The works are now in good condition, and it is not likely that operations will be interrupted in the future. The geology of the neighborhood has received expert study, with a view to ascertaining the sources and courses of the underground waters, and the information obtained is valuable.

During the twelve months ended on September 30, 58,339 long tons were milled, yielding 23,434 oz. fine gold. A further 7078 oz. were obtained by chlorination and cyanidation, making a total output of 30,512 oz. The gold contents vary in depth. At the point where most of the work is being done, the ore was richest at the 900 and 1000-ft. levels. At the 1100-ft. level the grade has fallen off, but judging from the records of variation in the upper levels, the engineers are hopeful of finding better ore again, as they continue sinking. There is plenty of ore ready for the mills, and now that extra expenditure has come to an end, there is every prospect of a divisible profit being made during the current year.

Trouble among diamond producers continues. The latest news is that the Lace Diamond mine suspended operations owing to the impossibility of selling the output. This mine is situated 16 miles northwest from Kroonstad, in the Orange River Colony, and was opened up by J. Dale Lace. Active operations commenced in 1902, but during 1905 an interruption was caused by shortness of water-supply. Since April, 1906, the work has been continuous until last week. On December 31, 1906, the amount of blue ground on the floors was nearly 1,000,000 loads. The average contents are from 10 to 13 carats per 100 loads, as compared with 25 to 40 carats per 100 loads at the various mines belonging to De Beers. The company owning the mine has never made any profit, so under present circumstances, a shut-down is doubly wise. Another indication of the condition of the diamond trade is the decision of the Premier Diamond Mining Co. to cancel the announcement made in December with regard to dividends. It was then stated that the results of working for the year ended October 30 warranted the distribution of a dividend on the ordinary shares amounting to £400,000. Of this amount the Transvaal government would be entitled to £240,000, while £160,000 would go to the shareholders. When the De Beers company announced shortly afterward that it would pay nothing at present on the ordinary shares, the Premier company desired to rescind its dividend notice. The difficulty, however, was to induce the Transvaal government to forego its rights. An agreement between the Government and the company has now been made, so that the company is enabled to keep all its funds intact.

The engineer of the Champ O'Or in the western portion of the Rand has issued a further estimate of the life of this mine. He considers that it will last until the coming May. If subsidences take place the mine will close down before then. On the other hand, if no sign of subsidence appears, it will be possible to extract the ore left in the pillars in the upper part of the mine. In addition to ore in the mine, there are accumulations of slime still to be treated. These will last, at the present rate of treatment, until the end of the current year. The mine is owned in France and has been worked since 1891. There are 60 stamps, and the output has varied from 20,000 to 50,000 oz. gold per annum. The company has not on the whole been a very successful one financially. The approaching exhaustion of this mine follows closely on that of the Bonanza. The two mines were unlike, for the latter contained the highest grade ore on the Rand and made large profits. Both, however, were small mines, a fact which accounts for their comparatively early exhaustion.

Map of South Africa.

At the present time it is not easy to raise capital for new ventures. It is of interest to note therefore that the Commonwealth Oil Co., owning shale oil deposits in Australia, has been successful in placing a large issue of debentures. This company is under the control of two of our large publishers of popular literature, Newnes and Harmsworth. Another new issue making its appeal to the public is the Vryheid Natal Railway Coal & Iron Co., which has been formed by G. H. Bonas for the purpose of acquiring and equipping the Hlobane colliery near Vryheid, in Natal. This company is asking for £175,000, to be used for outfit and for the completion of a branch railway. The coal deposits are extensive and the company hopes to obtain a share of the export trade at Durban. The property also contains iron and manganese deposits, of which I hope to give particulars at a later date.

Mr. Hermann Landau created some stir in the West Australian market this week by stating publicly that in his opinion the Western Australian government should spend £100,000 or £200,000 on a thor-

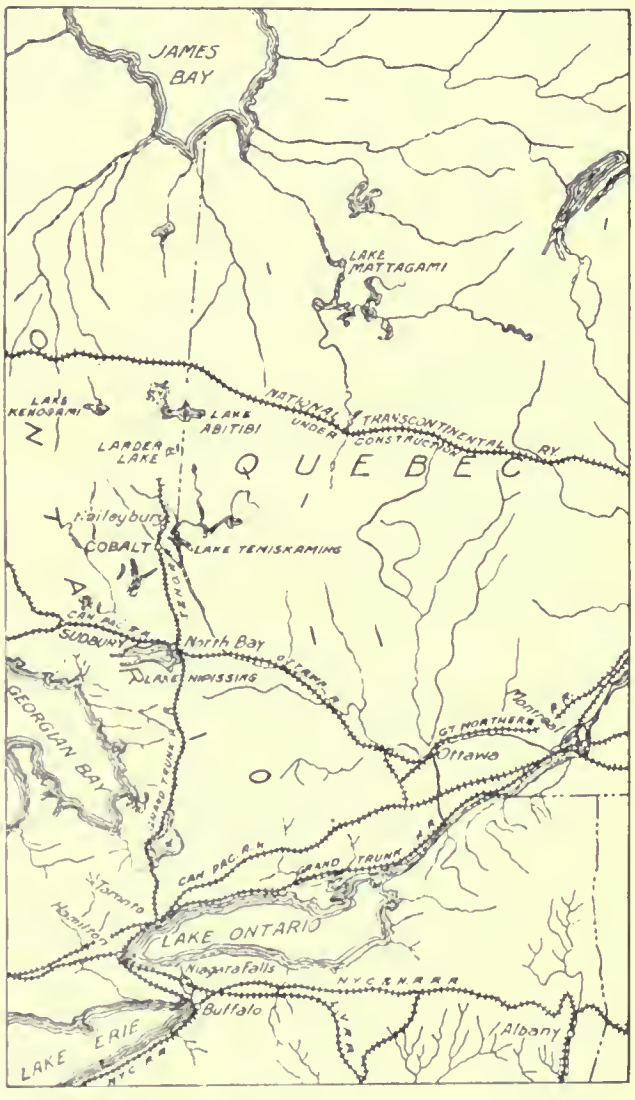
ough geologieal examination of the Kalgoorlie distriet. He was in a pessimistie mood, prophesying that many of the mines would have to be abandoned when the deposits beeame poor in depth. He did not reeeive much support, as it is generally felt that prospeeting at depth is not a government's duty. His remarks were made at the meeting of the Asso-eiated Northern Blocks; he took oeeasion to warn shareholders that the lower levels of the mine did not hold out mueh promise. He mentioned that the ore reserves on September 30 were 149,181 tons estimated to eontain 91,804 oz. gold, which amonts to 3½ years' supply. This is a fair enough prospeet for a mining company, and it is too early in the day to talk about falling back on public money for the purpose of prospeeting. A year ago the reserves were 101,769 tons, averaging 19.8 dwt. per ton, eompared now with 149,181 tons containing 12.3 dwt. It is this deerease in the average eontents that depresses Mr. Landau. Sinee the mine started work in 1899, the total ore treated to date has been 182,683 short tons, and the value of the gold extraeted has been £1,277,941, of which £577,500 was distributed as dividends, being at the rate of 165% on the capital. In addition, the eompany has eash on hand and a reserve fund invested in first-elass seeurities amounting to no less than £166,800. Practieally the whole of the expenditure on development and equipment has been paid out of profit and the mill and plant stand in the balance sheet at the nominal sum of £10,000. When you eome to think of it, is not Mr. Landau or his company in a better position to provide funds for prospecting than the government? Perhaps the directors and shareholders, having reaped a substantial profit, might like to win a reputation for public spirit?

TORONTO, CANADA.

Summary Reports of the Geological Survey.—Discoveries of Coal.—Shipments From Cobalt.—Other News.—Asbestos.

The summary report of the Geologieal Survey of Canada for 1907, just issued, giving the results of the investigations made by twenty parties in nearly every provinee of Canada, eontains mueh praetieal information as regards mineral diseoveries of eeonomie value, especially in the Canadian West. As the result of the work of D. D. Cairnes in the Yukon Territory, enormous quantities of available bituminous coal have been found. The coal measures that eross the Lewes river at Tantalus have been found to extend in a northerly direetion for several miles at least and in a southerly direetion for over 50 miles, crossing the Whitehorse-Dawson wagon road 70 miles from Whitehorse and in all probability extending considerably farther. Wherever a seetion has been made, two or more workable seams of good bituminous eoal have been found. In the places where it has been obtained at a depth, the eoal cokes satisfactorily. W. W. Leach, who eontinued work in the Bulkley valley, B. C., reports the diseovery of a new eoal area on the Goldstream about 2 by 2½ miles in extent, showing two seams of 5½ and 3½ ft. respeetively of elean bright coal. Another smaller area was found in the same loeality. Mr. Leach considers it fairly certain that no great coalfield exists in the Bulkley Valley district from Hazelton to the headwaters of the Moriee, though small isolated areas are known. It is not probable that much development will be undertaken on the coal properties situated on the Telkwa river and Goat ereek, until the route of the Grand Trunk Pacific is finally selected. D. B. Dowling's examination of the coal areas on the south branch of the Brazeau river behind the Bighorn range in the Rocky Mountain region, where a big coal-seam was found in 1906, has resulted in the finding of other seams. The workable seams have a total thiekness of 66 ft. 4 in. The area from Lake Temiskaming westward in Quebec Province has been a good deal prospected in the expeetation that the Cobalt formation might be found to extend in that direetion. Morley E. Wilson, in reporting his investigations in this region, states that no discoveries of eeonomie importanee have been made. Sinee the silver ores of Ontario are associated with the post-Huronian diabase, the limited extent of this roek in the area examined greatly reduces the probability of similar diseoveries.

The Survey has undertaken a systematie investigation of the coals of the Dominion by an exhaustive



Map Showing Position of Cobalt and New Districts in Ontario.

series of eeonomie and chemieal tests, which include eoal washing and (when necessary) dry eleaning, followed by boiler tests. Other portions are to be treated in gas-producers provided with devices for measuring the power developed, and competitive eoking tests will also be carried out. The co-operation of the mining and mechanical engineering departments of McGill University, of Montreal, has been seeured. The investigation is under the general direetion of J. B. Porter, R. J. Durley having charge of the boiler tests and producer gas experiments. It is proposed to secure sample lots of 10 tons of average coal from each mine. About 175 tons have been already procured from the mines of Nova Scotia and New Brunswick and subjected to the boiler tests and it is hoped to cover the Western coalfields this season.

Ore shipments from Cobalt for the week ending

January 25 amounted to 492 tons from the following mines: Coniagas, 33 tons; Foster, 20; La Rose, 150; McKinley-Darragh, 60; Nipissing, 32; Standard, 19; Silver Queen, 121; Silver Cliff, 26; Temiskaming, 29 tons. At the annual meeting of the Erie Cobalt Mining Co. on the 27th ult., reports were presented showing $49,000 expended on development. The company has on hand low-grade ore, the value of which is estimated at between $50,000 and $60,000. It was determined to install additional modern mining machinery. The shareholders of the Peterson Lake mine last week refused to ratify a deal made by the directors for the sale of 30 acres of their property to the Nova Scotia for 150,000 paid-up shares in the latter company. A good strike has been made on the Cobalt Lake property in an adit under the lake at the 86-ft. level. The vein is 2 ft. 6 in. wide, carrying native silver. The company has on hand four cars of high-grade ore. The Cleveland Cobalt recently struck a vein 7 ft. wide at the 125-ft. level, showing low silver contents. O'Neil Gordon, general manager, has resigned his position.——John Harris, superintendent of the McKinley-Darragh mine, has resigned.

A rich deposit of asbestos has been found about four miles from the village of Melbourne, Quebec. The vein is thought to be a continuation of one that has been successfully worked near Danville. Some Sherbrooke capitalists have become interested in the property.

DENVER, COLORADO.

Activity at Leadville.—Forest Supervision.—Activity in the San Juan.—Portland Meeting.—Routt County Coal-Fields.

Mining at Leadville is slowly picking up as the smelters are able to take more of the ore. The activity in prospecting for gold has resulted in the opening of the Margaret mine, 26 miles west of Leadville. This is a new property and is claimed by men familiar with the district to be on the extension of the old Yankee Blade vein. The famous London mine situated over the range in Park county is producing steadily. The open weather has particularly favored shipping. Twenty teams are now engaged in hauling the ore to Leadville. The leasing system is gaining favor in this camp. More than the usual number of leases have been granted thus far. Several of the mines are now working three shifts, but as yet most of the work is confined to prospecting and development of properties producing gold ore.

Confidence is returning to the mine operators in the San Juan region. The Snow Flake property at Red mountain and the Des Ouray property at Ouray have both resumed operations during the past week. Another shift has been added to the working force on the First National property. The recent strike reported at the Camp Bird has encouraged everybody and largely accounts for the general resumption of operations. The Emma Gold Mining Co. of Rico is at work installing additional machinery preparatory to sinking a shaft at the mouth of their main drainage adit. This company is also increasing its milling capacity by the addition of 15 stamps. The Pennsylvania tunnel at Telluride has been connected by a raise of 416 ft. with the Smuggler-Union workings. This adit was started about ten years ago; it opens an immense area of stoping ground, for the Smuggler vein is so persistent that it has been stoped for a mile continuously.

The Newhouse tunnel has proved such a success at Idaho Springs that preparations are now being made to continue the Lucania tunnel from Idaho Springs into Bellevue Mtn., where there are several valuable properties that can best be operated through such an adit. The tunnel is already 4209 ft. long, and several veins, yielding fair returns, have been cut. The old Burell mine on Alps Mtn. is being re-opened by G. E. Wroekloff under a lease. This mine has been idle for over twenty years. The shaft is being re-timbered and new machinery installed. Within the month the Burleigh tunnel will be connected by the Phillips raise to the bottom of the shaft of the Seven Thirty property. This will make leasing easier and more profitable at Silver Plume.

The Cripple Creek district has started off well for the first month in 1908. The production amounted to 56,785 tons, valued at $1,335,820. This increase in production is due in great measure to the recent cut in freight and treatment charges made by the United States Reduction & Refining Co. The competition between this company and the Golden Cycle is very keen, and the Cripple Creek operators are the gainers. Several old properties have been opened during the month and leases are in demand on almost every available property. Likewise several new and important finds have been made in the productive mines. All these factors, combined with the usual managerial hustle to make a good showing just before the annual stockholders meetings, resulted in an exceptionally good month.

The annual meeting of the forest supervisors of Colorado and surrounding States was held at Leadville during the first week in February. A great deal of interesting information was given out and some rather astonishing facts. The policy of the Forestry Department in keeping the forest reserves better and more efficiently supervised has been severely criticised, and the Government has been accused of meddling with the affairs of private individuals. The need of activity on the part of the Forestry Department is plainly evident when it is learned that fully 75% of the homestead locations in the Las Animas reserve alone are fraudulent. When the forest service first took control of that reserve fully $500 worth of timber was being cut illegally every day. The work of the Department is being enlarged, and hereafter it will employ expert miners and geologists to inspect all mineral claims that are to be located on reserves. As far as possible the Department intends to exclude mineral areas from future reserves.

The San Juan district continues active despite the slow recovery in the financial world and adverse climatic conditions at this time of year. Development work on the property of the Mountain Flower Mining Co. has been suspended until spring. This property is on the east fork of Deep creek, in a very precipitous region, and the prevalence of snow-slides makes it advisable to cease operations at present. At the Chipeta tunnel, near Ouray, repair work and cleaning out are being done by a small gang of men. The Silver Chief group is now shipping ore regularly from Telluride and more than the usual amount of development work is being done in the Bridal Veil basin, about four miles southeast of that town.

The Russell-Page Mining & Tunnel Co., which owns a group of five claims at the head of Cascade creek and has a lease on the Cynosure claim near Idaho Springs, is installing a boiler and air-compressor preparatory to continuing an adit to drain these properties. Considerable dissatisfaction is expressed by the operators and lessees with the ore-buyers at Georgetown. A local newspaper published a correspondent's letter in which the ore-buying companies are charged with fraud and collusion with the assayers. Whatever may be the real grounds for dissatisfaction, it must be remembered that grab sampling is not as accurate as the method employed at the samplers. Assays on samples taken

at random cannot be expected to check with a systematic sampling and assay.

It is now assured that the Moffat railroad is to be the only one leading into the Routt county coalfields. The Union Pacific recently completed its surveys from Wamsutter, in Wyoming, to Craig, in Routt county, and announced that the line would be built at once. It is to be regretted that this coalfield is not to have the advantage of competing railroad lines. Financial stringency and uncertainty regarding the outcome of the next presidential election are the reasons given for abandoning the project.

T. R. Countryman of Cripple Creek gave a lecture before the Colorado Polytechnic Society on February 8. The subject of the paper was 'Drainage in the Cripple Creek District.' After describing the geology of the great gold camp as a phonolite sponge cut by many basic dikes and held in an impervious granite cup, Mr. Countryman reviewed the history of the various drainage schemes and how they proved a common water-level. The adit that is now being driven will lower the present water-level 700 ft. and will require at least 36 months to complete. It will be of interest to compare the contractors' estimate of 24 months with the engineers' estimate when the tunnel is completed.——The annual meeting of the Portland Gold Mining Co. was held at Cheyenne, Wyoming, on February 3. The old officers were re-elected for the ensuing year. Recent developments in the lower workings of the mine have disclosed large high-grade orebodies. The same is true of many other mines in the district. It is now believed that the U. S. Geological Survey report on the district was too conservative. It is true that the orebodies seem to converge in depth. On the other hand, the ore is richer and as yet the veins are strong and well defined in depth. The experience of the Isabella mine, which has found high-grade ore-shoots in depth and been enabled to pay off all its indebtedness, is very encouraging to those whose ore reserves will be exhausted before the drainage adit is completed.

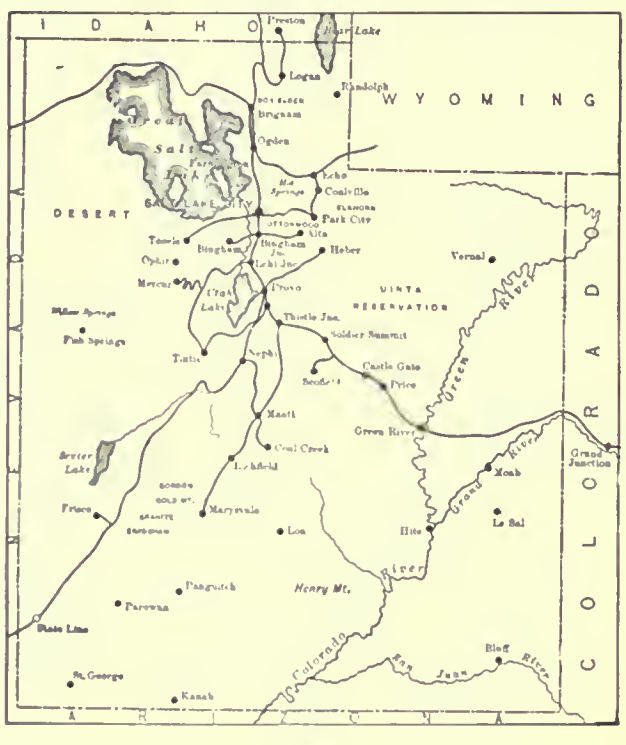
SALT LAKE, UTAH.

The Ontario Adit.—Ohio Copper Co.'s New Mill.—Utah Copper Co.'s Output.—Bond Issue.—Ogden Smelter.—Litigation Settled.—Utah Consolidated Resumes Shipments.

According to reports just received, the water in the Ontario No. 3 shaft at Park City has receded nearly 50 ft. below the 1100-ft. level and is lowering at the rate of nearly 4 ft. per day. The management of the Ontario Silver Mining Co. considers this to be positive proof that the last of the obstructions in the drainage adit have been found and that it is a matter of only a short time until the avenue will have been restored to its former usefulness. Water is flowing from four drill-holes from a parallel drift to the main channel at the rate of 5000 gal. per min. The adit was closed by caves just about three years ago.

The Ohio Copper Co., at a special meeting of shareholders at Portland, Me., authorized an increase in the capital stock from 1,000,000 to 1,500,000 shares, of the par value of $10. It is proposed to issue $2,000,000 worth of bonds, redeemable in stock at $10 per share any time prior to September, 1912. The funds derived from this issue will pay for the mill now under construction, with enough additional to build a second unit, thereby providing facilities for the treatment of 4000 tons of ore daily. In a report submitted by D. McVichie the actual amount of developed ore in the Ohio mine at Bingham is placed at 3,746,165 tons, of an average copper content of 1.6%; with 3,238,616 tons additional classed as probable ore above the 500 level, of the average copper content of 1.5%. It is anticipated that the best orebodies lie below this level and development at depth is now in progress. The mine is to be connected with the Mascotte tunnel from the Dalton & Lark mine at a depth of nearly 1000 ft., and it is expected that this work will be completed within the next 60 or 90 days. The Ohio ores concentrate on a basis of 18 tons into one. A noticeable feature about the Ohio mine is the increase in gold as depth is attained. In the construction of the mill, $653,579 has already been expended; the equipment includes two 24 by 16 in. jaw-crushers, four 20 by 6 in. jaw-crushers, eight 24 by 15 in. rolls, 144 jigs, sixteen 7-ft. Chilean mills, and 382 Wilfley tables. The slime plant will be equipped with 72 Wilfley slime-tables and 180 Callow tanks.

The output of the Utah Copper Co. during January was 130,000 tons of ore; this was treated at the company's mills at Garfield and Bingham, the



Utah.

latter handling 700 tons per day, 3,200,000 lb. copper being obtained. The ninth section of the Garfield mill will be in commission before the end of the month.——The mill of the Boston Consolidated Co., at Garfield, is reported to be working satisfactorily. Three 250-ton sections are in commission and the fourth will be ready this week.——The Utah Copper Co. has filed amended articles of incorporation with the Secretary of State, the capital stock having been increased to $7,500,000. The bond issue of $1,500,000 authorized at a special meeting of stockholders recently, according to advices received from the East, has been fully subscribed.

Owing to the numerous protests made by farmers residing in Weber and Boxelder counties, the Utah Mine Owners' Association has abandoned the project of making Ogden the centre for an independent smelter. Accordingly, the option on the plant of the Utah Smelting Co. will not be exercised.——All litigation having been brought to an end over title to the Snowflake and Mountainview groups in the Gold Springs district, Iron county, a syndicate has organized the Buck Mountain Gold Mines Co., with a capital stock of 5,000,000 shares of the par value of $1 each. Plans are being made to erect a mill

to treat 100 tons of ore daily, the plant to be almost a duplicate of the one now being operated by the Jenny Gold Mining Co., in the same district. Charles A. Short, of the Short & Elliott Co. of Salt Lake, is manager.

The Utah Consolidated Mining Co., operating at Bingham, will resume ore shipments on the 15th inst. to the extent of 800 tons daily, the product to go to the Garfield smelter of the American Smelting & Refining Co. for treatment, under a contract which is to run for one year with the privilege of two. J. B. Risque, the manager, says there has been no change in the plans of the Utah Consolidated in regard to the building of its proposed new smelter in Tooele county. However, there will be no hurry to start construction.

ROSSLAND, BRITISH COLUMBIA.

Operations of the Granby.—Possible Consolidations. —The Rossland Mines.—The Lead Bounty.

The Granby is the only mining company in this district that has shown any material progress during the past week. They have increased their operations since the beginning of the year step by step until they are now shipping 22,000 tons of ore per week from the mines to the smelter, where they have their full battery of eight furnaces at work. It is likely that the furnaces will be enlarged in the early summer, increasing their present capacity (3000 tons) by about 25%. There are now 800 or 900 men employed at the Granby mines and smelter, but there is still a small surplus of labor in the Boundary.

The annual meeting of the Dominion Copper Co. did not lead to the resumption of work and there are rumors that the Granby may absorb this company and the B. C. Copper Co. Some color is given to these reports by the recent examination of these other mines by Granby men. The officers of the Granby maintain there is nothing in this gossip, but to the average observer the plan seems feasible, as it would enable them to operate these mines at a good profit, even with copper as low as it is now. It is also stated that the Consolidated Co. has its eye on the Dominion property. As the Consolidated smelter at Trail is now treating ore from the Snowshoe mine at a profit, that carries only 1.4% copper, $1.50 gold, and 23c. silver, the same thing may be said of them as of the Granby.

The big companies here are recognizing the value of extending their operations over a broader field. The Granby is doing development work on good properties in the Similkameen and Rossland; the Consolidated at Rossland, Trail, Moyie, Phoenix, Sloean; the Le Roi No. 2 at Rossland and Silverton, etc. This is partly necessitated by the low-grade character of the gold-copper ore, to treat which successfully it is necessary to have a higher grade of ore for flux, and it of course also tends to more economical mining.

The Maple Leaf group has been bonded to New York capitalists and a small force of men put to work. At the Jewel mine they have a large body of gold ore blocked out that will require special metallurgical treatment. The superintendent is now at Denver seeking a fit process and making tests.

The Rossland mines shipped 5885 tons of gold-copper ore during the past week. The total for the year to date is 28,688 tons. The Consolidated Co. is opening up a fine lot of ore in the lower workings of their mine. From the War Eagle workings they recently extracted a 100-ton lot that ran $50 in gold, which is high for this camp. One newly developed orebody is 35 ft. wide, another is 65 ft. across.

Work is progressing at the Le Roi, Giant-California, and Evening Star. At the Blue Bird they have struck a silver-lead lode that runs $50 per ton. This being in the mooted South Belt, it is hoped that the strike will prove of importance and aid in the opening up of this portion of the camp.

The Hewitt mines, near Silverton, recently shipped five cars of ore running 141.6 oz. silver and 5% lead. They have a quantity of concentrating ore blocked out. This company has made many improvements in the handling of its product and is working steadily. Delegates have been sent East to present the case of silver-lead mining interests here in a proper light to the Government, in the matter of a further extension of the bounty on lead.

MEXICO.

Refinery Changes Hands.—Fresh Zinc-Shaving.

On the first of February the clean-up and inventory was completed at the Nonoalco refinery, Mexico City, of the National Metal Co., and the plant turned over to the Metal Refining Co. (Societé Affinage de Metaux), with whom the terms of sale by the former company were arranged just before the close of 1907. This refinery was started by the National Metal Co. in December, 1905, for the electrolytic refining of silver and gold from doré bars and cyanide and sulphide precipitate. The company confined itself wholly to custom work, filling a long-felt want, and in a short time had contracted almost the entire output of the great camps of Pachuca, El Oro, and Guanajuato, and was continually adding others, until its purchase and production were well in excess of 500,000 oz. fine silver and 25,000 oz. fine gold per month. Early last year the necessity of a new and large refinery became evident, and ground was purchased for this purpose. But the continued growth of the business and the consequent large amount of money locked up therein was a great tax upon the company's finances, so that when early last fall the strong French company appeared upon the scene and made a splendid offer to the National Metal Co. for its business, negotiations were entered into, and as it was soon seen that the French company would enter the field as a strong competitor if the sale was not made, the deal was finally consummated and the property turned over as stated above. Pending the inventory and clean-up, the bullion has been shipped to the new company's correspondents in France, but now work will be resumed at the Nonoalco plant, which will continue in operation until the completion of the new plant which the French company has already started at Cypress St., Santa Maria, Mexico City. The home office of the Metal Refining Co. is at 56 Provence St., Paris, and it is closely allied with Mirabaud et Cie. and the Comptoir Lyon Allemond. The Mexican directors are Hugo Scherrer, Jr., Guillermo Brockman, and J. Seekbach of Seekbach & Co., all of whom have for some years been large bullion dealers. During the two years that the National Metal Co. was in the refinery business, it handled something over 40,000,000 pesos worth of bullion, and deserves great credit for the work done; now, though not compelled to remain out of the refinery business, it will undoubtedly again resume the ore-buying that it had practically abandoned in order to devote its time and capital to the refinery.—— What promises to be a very successful enterprise and one that should be welcomed by every cyanide man, is that established by A. G. Baldwin, of Los Angeles, at Nonoalco, Mexico City. Here Mr. Baldwin has erected a small plant with the most modern machinery for the manufacture of zinc-shaving, whence the mill-man who has not his own plant may obtain without delay and for immediate shipment absolutly fresh and clean zinc-shaving, obviating the long waits for shipments from the States.

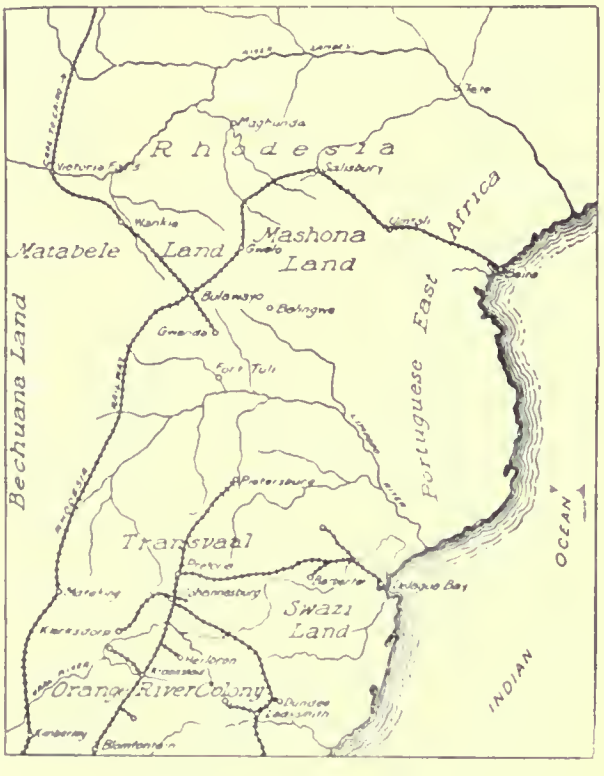
JOHANNESBURG, TRANSVAAL.

A Bold Hold-up.—Sunday Work in the Stamp-Mills. —State Mining Engineer.—Good Dividends.

Last week a desperate attempt was made by two highwaymen to hold up the officials of the Witwatersrand mine on their way to the bank with bullion valued at £12,000. The robbers were quite up-to-date, for they made the attempt by blocking the road with their motor-car. The officials had no idea that the men in the motor-car were highwaymen, until one of them was looking down the barrel of a revolver held by one of the robbers. As the officials did not appear anxious to give up the bullion, the robber pulled the trigger, but strange to say, the pin failed to fire the cartridge. At once, Mr. Allen, one of the officials, shot his antagonist through the stomach. The men were novices at the game, and ran to their motor-car. The wounded man soon became unconscious through loss of blood, and as the other fellow did not know how to manipulate the car he ran off across the veldt. Before night both men were captured, and a few days later the wounded man died. He was a resident of Johannesburg, a married man known to many people. It is stated that the other man was formerly on the staff of one of the mines. Times got hard with them, and this appears to have been their first crime. If it be true that 'nothing succeeds like success,' the reverse must be true that 'nothing fails like failure.' The complete failure of the highwaymen, and the death of one of them, will do more to discourage other desperadoes than any moralizing. There have been numerous attempts since the war to hold up banks and mines, but the failures have outnumbered the successes. On one or two occasions success has been due to having a confederate employed on the mine. The incident at the Witwatersrand will make people more careful in future, for although the gold is insured against such accidents, it is a sad thing for highwaymen to get away with, say, £12,000.

A week or so ago, the Comission now sitting to inquire into the workings of the mines received a deputation from the Witwatersrand Church Council, who gave evidence on the subject of Sunday work. As is well known, the Sunday law in this country is one of the best in the world, and compared with the laws in the Western States, where apparently no notice is taken of Sunday in the mining centres, the Transvaal is very well off. Only certain specified work is allowed on Sundays, and a contravention of the regulation is punishable by a fine as high as £75. The law allows the running of stamp-mills on Sundays. The delegation from the Council pleads that this too be prohibited. When it was pointed out the loss, especially to the poorer mines, that this new regulation would cause, the delegation suggested the construction of more stamps, but did not guarantee the capital to carry it out. Most people, especially church people, thoroughly sympathize with the delegation in their desire to do something for the mine employees, but the general opinion is that the very few men who work on Sundays are treated generously, and there is no necessity to change the law. It is improbable therefore that the stamp-mills will cease crushing on Sundays.

Many sarcastic comments have been made over the action of the Government in dismissing the Government Mining Engineer, H. Weldon, who for several years has successfully filled this important post. Mr. Weldon is well qualified for the post, both by training and by experience in this country. But he has a failing that Het Volk cannot readily forgive—he is a typical Englishman. It has been apparent for some time that he would be ousted from his appointment, and people have been amused to see how the Government would bring it about. There was little surprise, therefore, when it was announced



Map of the African Goldfields.

that Mr. Weldon, who rightly declined to resign, preferring to force the Government to dismiss him, was to be superceded by R. N. Kotze, who possesses the first qualification for this post, namely a good Dutch name and ancestry. Fortunately, Mr. Kotze is also a well trained engineer, and is about the only member of Het Volk that knows anything about mining. Mr. Kotze has been a consulting engineer in Johannesburg for some time, and knows the Rand well. Mr. Weldon's services will not be altogether lost to the industry, for he has consented to take the position of Chief Inspector of Mines.

The excellent dividends being announced in the daily papers are doing something to restore confidence in the mining industry. Some of the rich mines are paying out amounts this year somewhat higher than usual, while most of the less fortunate mines are announcing dividends above last year's declaration. There is no doubt that every effort is being made to woo capital back to the Transvaal, and the leaders are going the best way about it, namely by reducing working costs and thereby increasing the interest paid to shareholders.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

In a machine devised for surveying boreholes, the magnetic needle is clamped by the air pressure caused by a detonation of a cartridge.

Chilled-steel shot of extreme hardness, adapted to replace diamonds in drilling through many formations, is made by spraying or atomizing molten steel into cold water, thereby chilling it instantly.

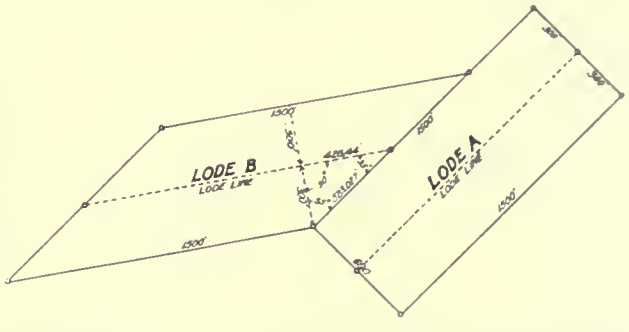
Cadmium is an important constituent in the zinc ore of the Joplin district in Missouri; mine-owners there engaged in the production of the metal in the beginning of 1907 and probably recovered during the year between 7000 and 8000 kg. of it.

Candles and lanterns, if handled with great care, will burn in air containing 3% carbon dioxide, but give very little light. They are extinguished by a very slight jar if more than 2% is present. An acetylene lamp will burn in still air containing a higher percentage of carbon dioxide than a candle will stand, but the flame becomes yellow and finally almost blue. In fighting fire in a mine it is necessary to have electric lights to work by where carbon dioxide is present in the proportion of 2% or more of the air.

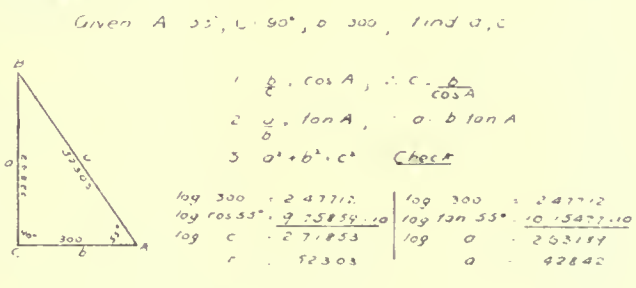
Dynamite is a peculiar and unreliable substance and must be handled with utmost care. At this season of the year there are always many accidents from dynamite explosions, nearly all of them resulting from carelessness or ignorance on the part of the men handling such explosives. Steam-shovel men are frequently called upon to furnish hot water with which to thaw out frozen dynamite. Water for this purpose should never be drawn directly from the boiler, as the temperature of the water in the boiler, which is generally more than 212° F. is too high for safety. A better way is to take it from the overflow in the inspirator, as such water is only about 60 or 70°, and while it takes a little longer to thaw the dynamite, it is much safer, and may be the means of preventing many accidents.

A prejudice exists among the prospect-owners of northwestern California against assaying as a means of determining the value of their properties. As most of the gold is in a free state they depend on the use of the mortar and gold-pan to give them an idea of the approximate amount of gold per ton of rock. Here is how this careless method worked out in a case in Trinity county: About five years ago several men who had considerable experience in a portion of Shasta county where the gold is only partly in a free state, bonded a prospect in the Coffee Creek district of Trinity county. They did not have any of the quartz assayed, but after much panning they concluded that they had a large vein of ore that carried $10 gold per ton. Then they organized a company and proceeded to erect a 10-stamp mill. When one 5-stamp battery was completed they made a test run of several weeks' length. It is doubtful that they even made a clean-up. At any rate the operation suddenly collapsed. These men had made the mistake of judging a Trinity county pan prospect by a Shasta county standard. This is not an isolated case; careful sampling and assaying are prime requisites to success in gold-quartz mining even in a district in which nearly all the gold is in a free state.

The locations embracing lodes A and B in the form on the diagram are properly made. The angle at which end lines cross a lode is immaterial so long as the lines are parallel, and the claim as located does not exceed the statutory length or width. The width is the perpendicular distance between two side-lines, not necessarily the length of the line connecting the



two opposite ends. As to grouping claims for patent purposes, as long as the claims are contiguous the law is satisfied. The Land Department allows patent applicants to exercise their own judgment as to the manner in which the claims join one another. The formula for determining the length of two sides of a triangle where all the angles and the length of the other side is known, is stated and applied as follows:



Given A 33°, C 90°, a 300, find b, c
1 c = a / cos A, ∴ c = a / cos A
2 b = a / a · tan A, ∴ b = a tan A
3 a² + b² = c² Check
log 300 = 2.47712
log cos 33° = 9.75859 - 10
log c = 2.71853
c = 521.03
log 300 = 2.47712
log tan 33° = 10.51927 - 10
log a = 2.99639
a = 428.42

The largest orebodies of the Cripple Creek district, Colorado, consist of a multitude of soft rich seams in hard nearly barren rock. Concentration by any method other than hand sorting is impracticable. When the rock is blasted, a large part of the valuable material in the seams is reduced to an extremely fine powder; another part adheres as crusts to the coarse rock. The fine is screened out and the coarse material hand sorted. At some mines the waste rock discarded by the sorter is washed before being thrown over the dumps, as it has been found that valuable fine adheres to these larger rocks. This sorting, washing and resorting is one of the items which bring the cost of ore production at Cripple Creek higher than in most camps in which other conditions are similar.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Conical Tube-Mill.

The Editor:

Sir—Some twelve years ago I conducted my first experiment with the tube-mill, in the endeavor to crush a rich slag containing a quantity of matte for wet concentration, after 6 by 42 in. high-speed rolls failed to do the work required. With the rolls the economic point was reached at 16 mesh. The tube-mill was brought to my attention as the Murphy 'barrel,' and I was prevailed upon to give it a trial as a last resort. The result astonished me; but it carried the work to the other extreme, and produced a slime which, as far as economic results were concerned, placed me in almost the same position as did the under-grinding by the rolls. While the work in this instance was costly, even though I made a gravity concentrate of about $200 per ton, the experiment in the form of experience was worth the price paid. I realized the great capacity of the device, and also realized that it would not fill the requirements for ordinary concentration on account of its sliming. As cyanidation was then in an undeveloped stage, the experiment was charged to experience, and five or six years later it was utilized as a valuable asset. In the meantime, other engineers adapted the developed tube, or pebble-mill, to cyanidation, until today it is accepted as one of the necessary appliances for the recovery of millions of dollars per year, where margins of profit are sometimes limited to cents per ton, instead of dollars.

It is a question, whether even now the full possibilities of the device have been given the consideration which it deserves as a gradual reduction apparatus. The tube has been fed and choked with undersized material, but it has gone on "doing business" in spite of abuse. Its great economic possibilities should have been the subject of more thought and experiment.

The pioneer in any line generally has to pay for his experience in cash or its equivalent, or as a sacrifice due to the criticism of his co-workers. In my own case it was with considerable temerity that I carried out the theory in a new device employing the tube-mill principle for crushing. The idea developed into laboratory tests and the laboratory tests into a practical working machine, that is, my purpose was to clear the anvil cushioned with the remains of previous work, before placing upon it the next task under consideration, an idea often and ably expounded by practitioners such as Philip Argall, Ernest A. Hersam, and others of their class. While I do not claim to have achieved the acme of their requirements or of my hopes, still I feel that in developing and bringing out the conical pebble-mill, I have accomplished not only a first step, but a stride toward filling a long felt want.

The first machine I devised on this principle, was for the extraction of sapphires from a soft tufaceous rock. To crush the rock, meant crushing the sapphires. The satisfactory accomplishment of this end was finally realized by employing a mill comprised of two cones, using the coarse lumps of the sapphire rock as grinders; a method that I had previously used in the ball-mill, when grinding without the intervention of grinding-balls. The result was that the sapphires dropped from their matrix like plums from a plum pudding. Then the question arose, as to how to get them from the machine. This was contrived by inclining the mill at any angle from the horizontal while revolving, when any particle smaller than the grinding body immediately sought and took up a zone of vertical stratification according to its size rather than its gravity, issuing in a stream from the mill. The result was a mixture of sapphires, quartz, iron pyrite, and other material, from an eighth to a half-inch in diameter. Here another difficulty in separation presented itself, which was finally overcome by employing gravity-jigs to separate the quartz and sapphires, and the Blake static-electric process for the removal of the sulphides.

To claim that sliming and coarse grinding can be accomplished in the same machine, appears to be unreasonable. That it can be done is illustrated by the case of the sapphires, and it is proved by the results accomplished by the conical mill adjusted for fine grinding, in competition with an ordinary tube-mill. The feed for the tube-mill was first crushed by stamps through 25 mesh, while the conical mill heading was the direct product of rolls, of which over 63% was coarser than 20 mesh (from ¼ in. to 20 mesh):

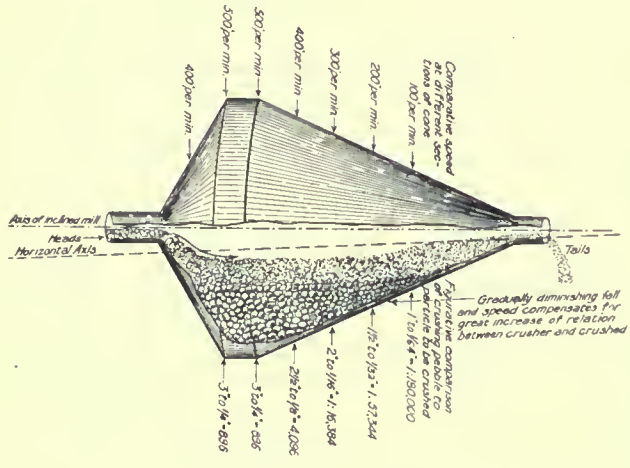
	Mesh	On 40 %	On 60 %	On 80 %	On 100 %	Through 100 %
Conical mill, charge of 2000 lb. pebbles, consuming 15 hp.	Head	75.7	6.6	5.5	2.3	9.5
	Tail	0.0	1.4	5.4	2.5	90.8
Regulation tube-mill, charge of 11,000 lb. pebbles, consuming 48 hp	Head	1.5	13.5	17.0	17.5	53.0
	Tail	0.0	0.5	1.5	2.0	96.5

In this coarse crushing by a pebble-mill, it was realized that we had attained a point which was of far-reaching interest to the metallurgist, even though we had been working with what has been termed a 'freak' machine; but a freak only in so far that it does something the other machine does not—for machines, like men, are freaks when they diverge from the trodden road of common usage.

In the most excellent article by Mr. Ernest A. Hersam in the MINING AND SCIENTIFIC PRESS of November 16, commenting upon the loss of power due to friction or the interference of ore particles among each other, he says: "All such friction is lessened by a free discharge of the crushed ore as it becomes reduced to the size wanted. This condition is difficult to obtain. To crush the ore the masses must be retained between the approaching surfaces that administer the force. But while too great an amplitude in the motion of the pressure surfaces tends uselessly to compress the fragments, grinding these one upon another, and distributing the force in many directions—too little amplitude, on the other hand, fails to do more than deform some of the particles, and failing to break these, it wastes what-

ever energy is so expended." These remarks not only apply to the crusher, stamp, or roll, but I believe more particularly fit the case of the ordinary tube or pebble-mill, whose consumption of power is so much greater than the work performed.

The tube-mill is ordinarily fed with material already ground to pass 20 mesh or finer; in which case fully 50% has already reached the maximum fineness desired, and therefore is a frictional interference to subsequent work. This work has been accomplished at a great expense of power; figuratively, it has been done and over-done; a sledge-hammer has been employed to drive a tack. To illustrate: A 1000 lb. stamp, dropping upon a 1 lb. piece of ore with a 6-in. drop delivers a blow of 500 ft. lb., or a relation of 1 : 500. In the subsequent crushing of the particle of the 1 lb. piece, the ratio is raised enormously. In the case of a 1 lb. pebble rolling down a rough 2 or 3-ft. incline, it would be pure supposition to figure the foot-pounds exerted;



400 per min
500 per min
500 per min
400 per min
300 per min
200 per min
100 per min
Comparative speed at different sections of cone
Axis of inclined mill
Heads
Horizontal Axis
Tails
Gradually diminishing fall and speed compensates for great increase of relation between crusher and crushed
Relative comparison of crushing pebble to particle to be crushed
1 to 64 = 1,980,000
1½ to 1 = 1,57,344
2 to 1 = 16,384
2½ to 1 = 4,096
3 to 1 = 896
3 to 1

Diagram Illustrating Grinding Action.

but assuming that it expends a relative amount of force, less the friction, and acting upon a mass a quarter-inch in diameter, the relation by weight will be 1 : 1024. But you cannot get this force successfully applied in either case unless you remove the interference due to the previously crushed material. In the case of the conical mill, the crushing bodies employed (pebbles) are of different diameters, such as naturally results from the wearing of the pebbles in their action upon the material to be ground; normal sizes being replaced as required. The larger sizes seek and maintain a relative position at the base of the cone or cylindrical part of the mill, where they act upon the newly fed particles. These particles, after being crushed, immediately pass forward to the next succession of sizes of pebbles, which in their turn act upon the second reduction, and so on up the incline of the cone, where a gradual reduction of applied forces takes place through the smaller sizes of crushing mediums, and less impactive force, due to the decreased peripheral speed.

An idea of these relations of crushing bodies to the particles to be crushed, can better relatively be understood by a classification of sizes of crushing masses, to size of particles to be crushed, as follows:

A 3 in. pebble is to a ¼ in. particle as 1 : 896
A 2½ in. pebble is to a ⅛ in. particle as 1 : 4096
A 2 in. pebble is to a 1/16 in. particle as 1 : 16.384
A 1½ in. pebble is to a 1/32 in. particle as 1 : 57.344
A 1 in. pebble is to a 1/64 in. particle as 1 : 180.000

Thus the crushing ability of the smaller pebble, is inverse to its size, and shows the waste of power in employing unnecessarily large bodies for work performed in the regulation cylindrical tube-mill, where classification does not take place, but a large proportion of the power is consumed in friction between pebbles and material already as fine as desired.

If a practical demonstration is desired of the sizing action that takes place in the cone outlet of the conical mill, I suggest as a simple experiment, with material on hand in almost any laboratory, the placing together of two glass funnels (preferably ribbed inside) with base to base, holding same together with adhesive tape, first partly filling one of the funnels with almost any material like fine dry sand to coarse gravel: revolve this apparatus at a slight angle from the horizontal, and watch the result. Explain it, if you can.

H. W. Hardinge.

New York, January 20.

Dam Made of Slag.

The Editor:

Sir—As mention has been made lately in your journal of a couple of dams built of slag, possibly a report of a new one may be of interest. The Union Copper Mining Co. of Copperopolis, California, was in need of a dam below the concentrator. The company's smelter is so situated that slag from the reverberatory furnace could be used in the molten state for the construction of the dam. In the past, the slag from the furnace has been removed by running it directly to the dump, in a sand-run about 75 ft. long. By extending this slag-run to a total length of 180 ft., liquid slag could be made to flow to the site of the dam. It is possible to dispose of a large amount of slag by this means, thus economizing the space available for a dump.

First a temporary mud dam was built across the creek and the accumulated water removed by a flume; then two concrete piers, erected on a concrete foundation, were constructed in the bed of the creek to hold the flood-gate. A culvert, 4 ft. square, was extended down the creek from the piers. The sides consist of roughly built walls of brickbats and the top, of a slightly arched bed of earth 8 in. thick at the sides. This bed of earth is supported by a platform of old boards resting on numerous uprights. When the slag has reached a sufficient depth, the boards and supports will be burned out, allowing the earth arch to collapse. It is expected that the brick walls will be washed away, the earth and brickbats being carried down the creek by the winter rains. An arched culvert of slag will be left. The face of the dam is constructed of brickbats laid in mud. A trench was dug down to bedrock of this wall and filled up with slag so as to decrease the possibility of leakage between the slag and the ground. The brick wall will probably fall in when the dam fills with water, leaving a straight face of slag.

No trouble has been experienced in running the slag to the dam in the sand-run. From the mouth of the run, slag is diverted as desired to any portion of the fill. The plan has been to discharge the slag at the face of the dam and allow it to flow down-stream. In this way the highest part of the dam is formed at the face, the slag sloping

from there down the creek. In the above manner we have been able to construct a good permanent dam at very little expense.

The Editor:

Concentration.

Sir—While 'slime' and the 'filter-press' are almost wholly occupying the field of metallurgical research, the 'concentrator man' is resting on past laurels and appears to be satisfied to allow chemistry to invade the field of mechanics. As far as the metallurgy of gold is concerned, except in rare instances, the problem is rather of a mechanical nature than chemical, for gold in ore usually occurs as a mechanical mixture and should be separated by mechanical means, although the original deposition was by chemical agencies. One can hardly imagine that the type of machine represented by the Frue vanner and Willley table is the ultimate product of mechanical genius for the separation of materials of different specific gravities.

While this may be a period of monetary stringency, compelling many of us to wait for better times, we might be using our heads and hands in attempting to solve a method of eliminating the chemical equation from the treatment of gold ores by improving or originating new ideas whereby we might take the slime problem into the realm of mechanics. The mechanic has given us a wellnigh perfect sliming machine, let us finish the job and give the chemist food for thought. We all know that concentration as now practised leaves from a trace to $7 per ton in the tailing from an ordinary ore, in fact, it leaves enough to make it worth while to employ auxiliary processes in order to complete the extraction. Part of the gold is in the form of fine metal that has escaped the plates and concentrators, and part is combined mechanically with sulphides of high specific gravity. Eliminate this loss and our problem is solved. We are not now considering silver or copper ores in which the metals may be in a chemical mixture whose specific gravity may be very near that of the matrix.

We have tried concentrating slimed ores on belt and table machines with water as the suspensory medium with very indifferent success, concentration in oil likewise with partial success, also flotation by means of gas, as well as air as a medium. Of these different processes I am inclined to believe the simplest and the most promising to be the last named. I am aware that various machines using air concentration are on the market, varying in point of effectiveness from the crude 'dry washer' of the desert prospector to the more delicate machines utilizing an air-blast on sized material. So far these have not solved the problem but, nevertheless, I am inclined to believe that the combination of fine grinding and air-concentration has many excellent features. We may at the outset use the results of our experience in practical concentration and try to formulate some ideas to govern us in solving the problem.

The first problem is perfect sizing. With a dry slime, graded screens will accomplish the result; with a wet ore, hydraulic sizing must be resorted to; for the solution of this problem may be with dry or damp ore in air or some other gas, so we must not overlook possible contingencies and especially any knowledge that will help us. My experience has been that the flat table is a better machine for concentrating mineral from slimed ores than the belt type and that to obtain good results hydraulic sizing as a preliminary process is necessary, but has not this hydraulic sizing been neglected? If we are to size at all, why not do it well? The inverted pyramid and cone are the general appliances used for the purpose, but an important principle connected thereto has had insufficient attention. I refer to the decreased upward motion of the water current as it nears the top of the appliance. I am aware that at the Smuggler mill at Aspen the management has a patent on a sizer embodying this feature. The remedy is a contraction of the annular space between an inner cone and the conic receptacle so that the rising water with suspended mineral will encounter a constant force, allowing the minerals of a given specific gravity time to settle before being carried over into the tailing. This is not sizing in its simplest form, it is concentrating and sizing, for fine metal or mineral will be carried over, but if pushed to a logical conclusion, with the annular space proportional to all the other factors, we may have a good concentrator. Now apply the principle to air-concentration and with all the factors constant we may imagine a state of equilibrium in the air-vessel, with the light particles in the upper stratum and the heavy material in the lowest. With coarse particles the condition would be impossible, but the 'fine grinder' has provided us with a very fine product that possibly has unconsciously solved or indicated the direction of our search, so let us use this fine material and endeavor to compete with the cyanide man.

ALGERNON DEL MAR.

San Francisco, January 19.

A Correction.

The Editor:

Sir—We note an article in your issue of February 1, on 'Drills for Stoping,' by Algernon Del Mar, and we certainly take exception to the remarks that he makes relative to the Hardsoeg drill. Beginning at the sixth line, he states that the drill is not so constructed that the air-pressure keeps the drill up to its work.

In view of the fact that the Hardsoeg company is the inventor of the air-feed attachment of the air-hammer drills, it seems a little hard to have a statement like this go before the public. The Hardsoeg company builds fully twice as many air-feed types of drills as any other manufacturer.

We enclose you their catalogue so that you may see for yourself. Such statements as this coming from Mr. Del Mar tend to do our business harm. We advertise and spend considerable money to have the public understand what the Hardsoeg people do build, and particularly the air-feed machines. Of course, it is evident that Mr. Del Mar has never come in contact with the air-feed drill of the Hardsoeg Co. or else he would not make such statements.

RIX COMPRESSED AIR & DRILL CO.

San Francisco, February 4.

[The catalogue, Bulletin No. 10 of the Hardsoeg Wonder Drill Co., does contain illustrations of air-feed drills on pages 8, 9, and 10 of that bulletin.—Editor.]

An oil pipe line has been built for transporting California oil across the Isthmus of Panama; its diameter is 8 in. and its length is 51 miles.

The deepest borehole put down for coal in Great Britain was completed during 1907; it attained a depth of 4531 feet.

DIFFUSION AS A FACTOR IN ORE DEPOSITION

Written for the MINING AND SCIENTIFIC PRESS
By COURTENAY DE KALB.

In an able paper* on 'Metallic Sulphides in the Tuffs of Santo Domingo,' Mr. F. Lynwood Garrison raises an interesting question as to the genesis of certain sulphide concentrations in un-fissured masses of an approximately homogeneous tuff. Orebodies of this type large enough to admit of economical exploitation, are rare, but the phenomenon of such segregations or concentrations is not uncommon, and the cause of it merits further consideration than it has received by geologists. In certain lead districts, for example, in southeast Missouri, the occurrence of detached masses of galena in unfractured limestone, entirely disconnected with either joints or bedding planes, is not unfrequently observed. Similarly, concretions of carbonate of lime, or of hydrated iron oxides, in sandstone are found in many places. The latter undoubtedly belong to the same type of segregation as the galena masses mentioned, and as the sulphide concentration described by Mr. Garrison, and they are peculiarly suggestive of the genetic forces operating, because they so frequently assume an approximately spherical form. They point to a force operating or tending to operate equally from all directions toward a common centre. This again demands immobility of the solution or ground-water with which the capillary or sub-capillary spaces of the rock were filled at the time of such concretionary growth. It is interesting to note that sandstones containing concretions do not present these uniformly spherical in shape; ellipsoidal, lenticular, and irregular forms are always common, although spheroids may predominate. Where concretionary sandstones are exposed to view the region has in most cases been elevated, and subsequently eroded. Hence the original water-table has been lowered, and such water as the rocks contain is true 'water of imbibition,' and is subject to capillary flow due partly to pressure (hydraulic head), and partly to evaporation, which latter calls into action the powerful force of capillary attraction, which is capable, in the case of sub-capillary openings of 0.0002 mm. diameter, of lifting water against gravity to a height of 166 m. Such elevation of rocks then, causes capillary flow of water through them, which takes place both vertically downward and upward, and to a certain extent horizontally toward hillsides. In sandstone beds where concretions exist, and under the subsequent conditions described, it almost invariably happens that accumulations of calcite, selenite, and limonite, one or all, according to circumstances, will be found where the sandstone rests upon an impervious bed of shale, and to a lesser degree, though sometimes in large aggregations, as a subsoil crust upon the sandstone on the tops and sides of the hills.† These phenomena are observable throughout the uplifted Tertiary strata of California. The lower mineral accumulations are due to the downward leaching of the sandstones under normal gravity flowage of the solutions; the upward and lateral concentrations represent deposition by evaporation during the long dry seasons, the contributions being maintained by flow induced by capillary attraction to replace the water evaporated. The interestingly pertinent point in all this is that the later leaching and concentration has not been at the expense of the previously formed concretions.

By laboratory experimentation it was long ago demonstrated that in a concentrated solution of a salt containing immersed crystals of the same salt, the largest crystal will grow at the expense of the smaller until the small ones have been entirely dissolved and re-crystallized. This force of crystallization has been imperfectly investigated, but it is a force (having power to cause simple migration of salts, without diffusion, and without movement of the solution) with which we have to reckon in nature, and the influence of it in helping to effect mineral segregation in rocks may be very great. It has probably been operative in the cases of the concretions in sandstone and of the galena concentrations in the limestone, although in the latter it has been complicated with metasomatic replacement, while in the sandstone concretions the sand grains have merely been cemented by a deposition of the lime or iron salts in the interstitial spaces.

The principle of crystal-growth referred to demands concentration of the solution as a preceden condition. The saturation point for any salt depends upon pressure, temperature, and other salts and gases in solution, and is consequently subject to wide variations for any given salt. A solvent in contact with a salt will become saturated, and will then promptly proceed to diffuse the solute in accordance with the well known laws of osmotic pressure. This will continue until homogeneity has been established throughout a solvent of equal temperature. The osmotic pressure is a function of the concentration of the solution but if the solution is accompanied by ionization the pressure is increased. Moreover, by Soret's principle, the concentration increases toward the cooler portion of the solution.

We have here available, competent forces for the migration of salts, quite independently of any movement of the solutions themselves, within limits of distance yet to be determined by experiment, and also competent (in the case of saturated solutions) of producing growths of crystalline masses which could result in such concentrations of minerals as are often found in rocks. The amount of water contained in sub-capillary openings is small relatively to the solid mass of the rock, while the area

*MINING AND SCIENTIFIC PRESS, September 7, 1907.

†Since writing the above, corroborative observations have come to my attention in an interesting and able Bulletin (No. 35) of the U. S. Department of Agriculture, on 'Alkali Soils of the United States,' by Clarence W. Dorsey, as follows (p. 14): "*The greatest movement of alkali salts is due to capillarity which operates through surface tension.* When water moves by surface tension the films around the grains move. As soon as the gravity water has drained away, the movements become entirely by surface tension. A loss of water due to evaporation changes the curvature of the water films and starts a capillary movement toward the point where the evaporation takes place. But when water moves by capillary action it is the water in the smaller spaces that moves, and not the water which is in the larger non-capillary spaces. Therefore, the water which was drawn back into the capillary spaces, and which carried some of the alkali salts as it flowed down into the soil starts upward and carries with it the salts in solution. * * * * Any evaporation which occurs must take place within the soil at the top of the capillary column, the water vapor escaping by diffusion through the layer of the dry soil above. Recent determinations made in the laboratory of this Bureau have shown that an evaporation of this kind does take place within the soil. Since dissolved salts cannot rise above the point where evaporation is taking place, an accumulation of salts must take place within the soil at the upper end of this capillary column."—AUTHOR.

of contact between the solution and the particles of the rock is correspondingly enormous. Hence a condition of saturation of the solution with reference to the soluble mineral matter present would not seem to be difficult of attainment. Sub-capillarity is usually said to exist where the maximum diameter of the open spaces is 0.0012 mm. and the openings in most close-textured rocks are less than this, and the area of contact of the solution with the enclosing wall increases inversely as the size of the opening.

Flow of solutions through capillary channels takes place readily under favorable conditions, but flow through sub-capillary openings is greatly reduced, the retardation increasing rapidly with decrease in the diameters of the spaces, until at a diameter of 0.0002 mm. it is practically nil. The entire quantity of water in the sub-capillary spaces is probably within the limit of molecular attraction of the wall (assumed by Quincke to be about 0.00005 mm., although manifestly it can not be a constant) and this practically precludes sub-capillary circulation under deep-seated conditions. Flow of water is also retarded by an increase in the amount of the solute, thus giving another reason for deeming it questionable whether close-textured rocks below the level of permanent ground-water are capable of contributing appreciable additions to the circulation through relatively open channels with which they may be in contact, except through ramifying capillary openings, shrinkage cracks, shear planes, and other spaces of diseission, exceeding in diameter or width twice the distance to which molecular attraction, that is, surface tension, may exert its influence. But this would not seem to preclude the solutions contained in rock masses, the porosity of which is reduced to sub-capillary dimensions, from playing an important part in the re-arrangement and concentration of minerals within them by diffusion. This might in some cases result in the formation of ore-bodies of workable size.

While in the foregoing argument osmotic pressure has been considered as a means for facilitating concentration by the growth of larger crystals at the expense of smaller ones, it is noted that where metasomasis occurs osmotic pressure is capable, without necessary movement of the solution itself, of contributing material to continue the reactions, and that for this office saturation of the solution is not essential. In fact, ionization, which obtains where such chemical interchange takes place, is a phenomenon occurring most generally, and to a greater extent, in dilute solutions. By such means it may be possible to explain the peculiar conditions observed by Mr. Garrison.

AN INTERESTING USE of paper is in the making of gas-pipes. Manila paper cut in strips, as wide as the length of the pipe to be made, is put into a receiver filled with fused asphalt, and rolled solidly and uniformly around a rod or core of iron until the desired thickness is obtained. After the pipe, thus produced, has been submitted to a heavy pressure, the exterior is covered with sand, and the whole cooled in water. The core is then removed, and the outer surface covered with a waterproof product.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

The superintendent of the mine directed a miner to work in a room adjoining a new entry, which entry was the only means of access to the room where the miner was directed to work; the superintendent further directed the miner to get empty cars at a switch in such entry leading to an adjoining room. While the miner was in such entry in the discharge of the duty which he was directed to do, he was injured by falling rock from the roof of such entry, which had not been properly supported. In an action for such injuries the mine owner was estopped to claim that it was not liable for the reason that it had not accepted and did not control such entry.

Garard *v.* Manufacturers' Coal Co. (Mo.) 105 S.W. 767 (Nov. '07).

A miner was directed to go through an entry down to the switch in front of a particular room in the mine to get an empty car. While opposite such room he heard a cracking of rock in the neck of such room, and warned a miner working therein to look out that there was danger. Not finding a car he started to return and when six or eight feet from the room where the other miner was working, a rock from the roof of the entry fell and injured him. He neither heard nor saw any indications of danger in the entry, but did see and hear the chipping and cracking in the neck of the other room. In an action for such injuries, it was held that the finding of the jury that the miner was not guilty of contributory negligence would not be disturbed.

Garard *v.* Manufacturers' Coal Co. (Mo.) 105 S.W. 767 (Nov. '07).

The lessee in a lease of land for mining oil and gas was enjoined from removing property placed on the land by him, where such lease was taken by him as a matter of speculation, and he did nothing until other parties acting under a prior lease commenced prospecting for oil and gas, and after a temporary injunction against such parties, the lessee went on the land and began prospecting over the protest of the land owner.

Bruner *v.* Hicks (Ill.) 82 N.E. 888 (Oct. '07).

A ground foreman in mining operations conducted under the supervision of a general superintendent or manager, is a fellow servant with the miners whose operations he is directing, especially so where his duties were to direct the miners where to set up the drill, direct the shovelers where to shovel, direct the location of the underground tracks, and look after everything underground; and where it was a common practice for him at times to help the workmen who were laboring under him in actual drilling of holes, laying the track, and other such work, and where he was subject to the general orders of the superintendent, and notwithstanding he hired men to work in his department and discharge them, but did not pay their wages.

United Zinc Co. *v.* Wright, 156 Federal 571 (Oct. '07).

A drilling man in a mine was held to have assumed the risk of injury where it was the usual known custom to move the drills by hand up stopes having a practical grade; and he was not relieved from such assumption of risk by reason of a complaint made to the foreman and a promise on his part to secure other appliances for moving the drills, where such foreman had no authority to do so, either actual or apparent, and whose only duty was to report the complaint to the superintendent, under whose direction all the work was conducted, but which he failed to do.

United Zinc Co. *v.* Wright, 156 Federal 571 (Oct. '07).

NATIONAL MINING BUREAU.

Our readers will be interested in reading the text of a joint resolution introduced by Mr. Dick, in the Senate of the United States and reported favorably by the Committee on Mines and Mining. It read:

To provide for the establishment of a Bureau of Mining Technology:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That there is hereby established in the Department of the Interior the Bureau of Mining Technology, whose purpose shall be to make technologic investigations and reports on methods of mining, extracting, and utilization of the mineral substances of the United States and its noncontiguous territory, with a view to the betterment of the mining industry, the improvement of mine conditions, and the prevention of accidents and the waste of materials.

SEC. 2. That the President, by and with the advice and consent of the Senate, is hereby authorized to appoint a Director of the Bureau of Miuing Technology who shall receive a salary of six thousand dollars.

SEC. 3. That the Secretary of the Interior, with the advice of the said Director, is authorized to appoint such experts and others as shall be necessary to carry out the purposes of this act: *Provided*, That the Director and members of the Bureau of Mining Technology shall make no examinations for private parties or corporations except where such examinations involve the question of public safety.

At the same time a bill was introduced by the same Senator, but the Committee did not endorse it. The bill read:

To provide for a branch of mining technology in the Geological Survey:

Whereas, the mining interests of the United States yielded during the calendar year nineteen hundred and seven an increase to the nation's wealth of nearly two billion dollars; and

Whereas it is desirable that more adequate recognition should be given to the industry, not only by the more extended examination of the geological distribution of the mineral resources of the country, but also by the investigation of mining and metallurgical methods with a view to promote the better utilization and conservation of these mineral resources; therefore

Resolved by the Senate and House of Representatives of the United States of America in Congress assembled, That the Director of the United States Geological Survey be, and is hereby, authorized, under the direction of the Secretary of the Interior, to extend the examination of mineral resources and products of the United States and its non-contiguous territories so as to include the investigation of all mining and metallurgical methods in so far as such investigations bear upon the more efficient utilization of the material resources of the country, and particularly upon the accidents and dangers of the mining industry.

SEC. 2. That a branch of mining technology be, and is hereby, established in the United States Geological Survey for the purpose of providing for this investigation of mining technology.

SEC. 3. That the Secretary of the Interior shall report to the next Congress.

A discovery of magnetic iron-ore, said to be somewhat similar to the ore from which the Swedish iron and steel is made, is reported to have been made on Crown land on South Island, New Zealand.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

A specimen of gneiss was sent by S. C., of Santa Barbara.

A specimen of obsidian came from A. J. L., of Salt Lake City.

A specimen of diorite came from P. B., of North Yam Hill, Oregon.

DeY, of Dolomi, Alaska, sends: chlorite, quartz, and magnetite grains.

The three rocks from Arispe, Sonora, sent by A. T. T., are rhyolitic breccia.

A specimen of chloritic gneiss was received from W. E. S., of Quartzite, Arizona.

T. H. O., of Humboldt, Ariz., sends an altered volcanic rock, perhaps a rhyolite tuff.

W. C. McD., of Princeton, B. C., sends: No. 1, black obsidian; No. 2, common opal. Neither of value.

D. G., of Terrazas, Mex., sends: No. 1, quartzite; No. 2, rock too much altered to classify; No. 3, quartzite.

The two specimens received from E. T., of San Antonio, Tex., are: No. 1, altered feldspathic rock; No. 2, volcanic tuff.

R. E. H., of Weaver, Ariz., sends: No. 1, yellow ochre; No. 2, pegmatite; No. 3, chlorite-schist; No. 4 to 6, granitic rock.

The rock sent by E. W. S., of Whitebird, Idaho, is serpentine containing cuprite and chalcocite, and coated with chrysocolla, all copper minerals.

The specimens from Wonder, Nev., marked H. G. G., are: No. 34, biotite-andesite; No. 35, feldspar-porphyry; No. 36, altered rhyolite; No. 37, rhyolite.

The specimens sent by D, Alleghany, Cal., are: No. 1, mica-schist; No. 2, altered schist; No. 3, pyritized talcose schist; No. 4, sulphantimonite of copper with some lead, bournonite.

W. L. H., of Phoenix, Ariz., sends: No. 1, volcanic tuff; No. 2, schist; No. 3, aplite; No. 4, altered volcanic rock; No. 5, hornblende-andesite; No. 6, sedimentary rock; No. 7, metamorphic rock; No. 8, dacite.

The specimens from Fairview, Nev., marked R. O. G., are: No. 18, meta-rhyolite; No. 19, quartzite; No. 20, calcareous shale; No. 21, slate; No. 22, calcareous rock; No. 23, silicious limestone; No. 24, contains gypsum; No. 25, gypsum with earthy limonite; No. 26, contains gypsum.

CONCERNING SUPERINTENDENTS.

Written for the MINING AND SCIENTIFIC PRESS
By ALFRED ALLEN.

In two years I have swung around a loop of seven thousand miles, studying men, machinery, and mines. Some of the superintendents I have worked under were not only amusing, but instructive regarding danger points.

For instance; at one mine there was the Sneaky Superintendent. He would hide around the shaft-house at night, when the men were eating their midnight dinner, to see if they made any remarks about his lordship. They accommodated him, for they soon learned his methods by his carelessly repeating some stories they had told. Anyone who knows the A. B. C. of human nature knows the kind of work they would do for such an over-lord. He had taken a $10 course in a correspondence school and signed himself M.E. I once asked him what M.E. meant, and he said: "Mining Expert." This mine was in New England, and he was boasting continually of the big Western mines he had managed. One of the men had a brother in the West and wrote to make inquiries. Word came back from the mines that they had never heard of this "mining expert." His company was formed of wholesale druggists, probably as impressed by his M.E. as if it were an M.D.

Another I worked under was the Fussy Superintendent. Nothing was right unless done just his way. I've seen him order a machine-drill taken down after being set up by a driller who had mined for ten years. Then he would waste two hours setting it up his way. The rock above and below had to be faced off smoothly and no wedges used. Honest men refused to waste the company's time and were sent down the mountain. Only grafters were left who were willing to humor him and to sit around and visit while he fussed away, running the drill himself, or played with a pick at the face of the drift. Four hundred feet that he ran in soft shale cost the company $30 per foot.

One instance will show his usual method. A nut worked loose and fell off the top of the upright boiler he had placed 20 ft. in the tunnel. He called all the outside men to help search for it in the water and muck. They searched for an hour, shoveling out everything, giving the tunnel mouth a dentist's clean-up. But no nut could be found. A man suggested that there were nuts of the same size in the blacksmith shop. But no, that particular nut must be found. Another hour passed, but one of the men became so disgusted at such waste of time he slipped to the shop and secured a nut. Returning he stooped as if searching under the fire-box and cried, "Here it is!" It was put on. The superintendent said, "There! I told you we'd find it. See how well it fits." Those who had no conscience laughed.

Such second-childishness seems impossible in this day, but it is a fact. He held his position because he had promoted the property, and those who bought stock knew no better or didn't care.

In Alaska I met a type even worse than this. He might be called the Conceited Superintendent. That means ignorant, also. It was his first job over men, and his little head had swelled so he couldn't say "Good morning" to a workman. Anyone who has lived in the region of continual drizzle knows that men who are compelled to live in tents, sleeping in their wet clothes, trying to do a day's work for $2 and board, need something more than their monthly pittance and a drunk.

His face was like a pan of sour dough from which cookie has just withdrawn his fingers. He was honest as to dollars. Had he been really honest in a finer way, he would have resigned, for his dense ignorance cost the company many thousands. Everything was mismanaged, from the steep tramway built for horses, but up which they couldn't pull more than themselves, to the pipe connections that were put in without a single union. Everything went at sixes and sevens because he insisted on doing the thinking for every man on the job. He had a foreman who had thoroughly learned his business during thirty years. But he was so jealous of him he couldn't hear of his giving an order to the night shift without reversing it. He went into the drifts and told each one of the old miners where to put every hole. Of course, the honest ones put them where they would move most rock—after he had gone to bed. He nagged every man until only black looks and curses were the rule. One or two old gambling and smuggling cronies were his pets and could do no wrong.

For a dollar steel pin on the donkey a whole gang was held idle till the launch could make a 10-mile trip and bring a new one from town. When I respectfully suggested that we keep two pins on hand so we would lose no time and the millwrights not be kept waiting for timbers, I only won his enmity. Because I saved the cable one day, contrary to his orders, which would have wrecked it, I was punished by being put at the hardest job on the place, breaking rock to keep the crusher busy in the night shift, a task that, after I left, kept two men hustling. I was amused, for I should have known human nature better. He made the tone of the camp so bitter against himself that when every one saw a main shaft bending so that it must soon break, they said, "Oh let him see it. He knows everything, and is doing all the thinking on the job. He'll fire the man who dares tell him." They didn't try to save it. It broke the next day.

The big pipe that carried the water to the compressor became filled with tons of gravel and broke several times, costing hundreds and weeks of delay. He wouldn't put in a gravel trap at the penstock because a workman suggested it.

Why speak of the many things that wasted time and money? Just one little instance will show his whole unbusinesslike method. He would allow only one large monkey-wrench on the place because wrenches cost a few dollars. But one man was kept busy chasing from the face out to the blacksmith shop, from the shop down to the mill that was being built, from the mill to the compressor room, from compressor down the mile of tram to the donkey engine for that one big wrench. The time that that

nipper put in finding that wrench would buy a case of wrenches, but the superintendent, like all ignorant superintendents, did not reckon time as dollars. The man who hinted at another wrench was in disfavor at once. The only men he could keep for a second pay-day were Slavs or Dagoes who had so little manhood or pride in their work that they would submit meekly to any amount of bullying as long as their monthly check was sure. His being a superintendent was a joke throughout all that region. And he kept them laughing. He kept his place by toadying.

I was once telling these and other things about him to the famous owner of a mine I was visiting. He has worked up from a miner and superintendent to the making of a score of millions out of one mine. As I finished, he remarked, "I'll bet anything he was strong on dignity."

"Yes, very," I replied.

"I've always found," he said, "that dignity is a mantle assumed by ignorance to hide itself."

I met one man who was drawing $450 per month as superintendent. He never went near the mine, but kept a dipsomaniac brother on it as watchman. This case hardly comes under the head of superintendence, but frenzied family graft.

As contrasts to these types I met many who were an honor to manhood. I am glad to say they were the great majority. For instance, one man I met in Nevada. He had what is called 'tact' in women, but 'horse-sense' when a man possesses it. He took pains to know every man's first name. And he called him by it with a cheery "Good morning, Jack," or some other greeting, no matter how many times a day he passed him.

He made every man his personal friend who worked with a will. Of course it was only his work he really had an interest in, but the men put such a life into it that he was worth much more than his salary. It was a pleasure just to visit his place. He saw that his men were warm, had a drying-room, and decent places to sleep. He put in a reading and game room. The men felt they had a home and regretted leaving. All these things paid big dividends.

For instance, one little trick of his: Sometimes he would say, "Now, boys, the work's behind what we should do. I'm getting up against it. If you'll help me out so many feet by Saturday night, we'll have a chicken dinner." They would even work overtime to help him out, and the company profited many times the cost of those chickens.

Practical steps in the direction of winding by electricity have been taken at collieries in South Wales and at the mine of the Tarbrax Oil Co., Ltd., in Scotland. Experience tends to show that, compared with electricity, winding with the steam-engine is cheaper in installation and in working costs, and consequently that when a steam-raising plant is available the steam winding-engine is to be preferred.

Aluminum is now manufactured by electric methods at a number of works controlling over 84,000 horsepower.

ADAPTATION OF A STEAM-DRIVEN COMPRESSOR TO WATER-POWER.

Written for the MINING AND SCIENTIFIC PRESS
By HORACE G. NICHOLS.

The following notes on the adaptation of a steam-driven compressor to water-power may be interesting:

The compressor is an Ingersoll, type D, duplex-steam duplex-air, with a capacity rated at 7 drills. The conditions that favored the change were: The increased cost, due to a diminishing supply, of cordwood for making steam, and the fact that a site was obtainable 3000 ft. from the mill-building in which the compressor was originally installed, where all the water, available for power, passing through the plant, could be obtained again under a head of 315 ft. A flume and pipe-line were already in existence for the conveyance of the water to this lower site. The first intention was to install a water-motor and transmit power by a rope-drive to the compressor-shaft, but this plan was thrown out in favor of a water-wheel being substituted for the fly-wheel, and later of converting the fly-wheel itself into a motor, by attaching buckets. The new site is on a wash of loose sand, clay, and boulders, and pile-driving was out of the question. These facts were largely responsible for the aim to have the foundation as inherently compact and strong as possible.

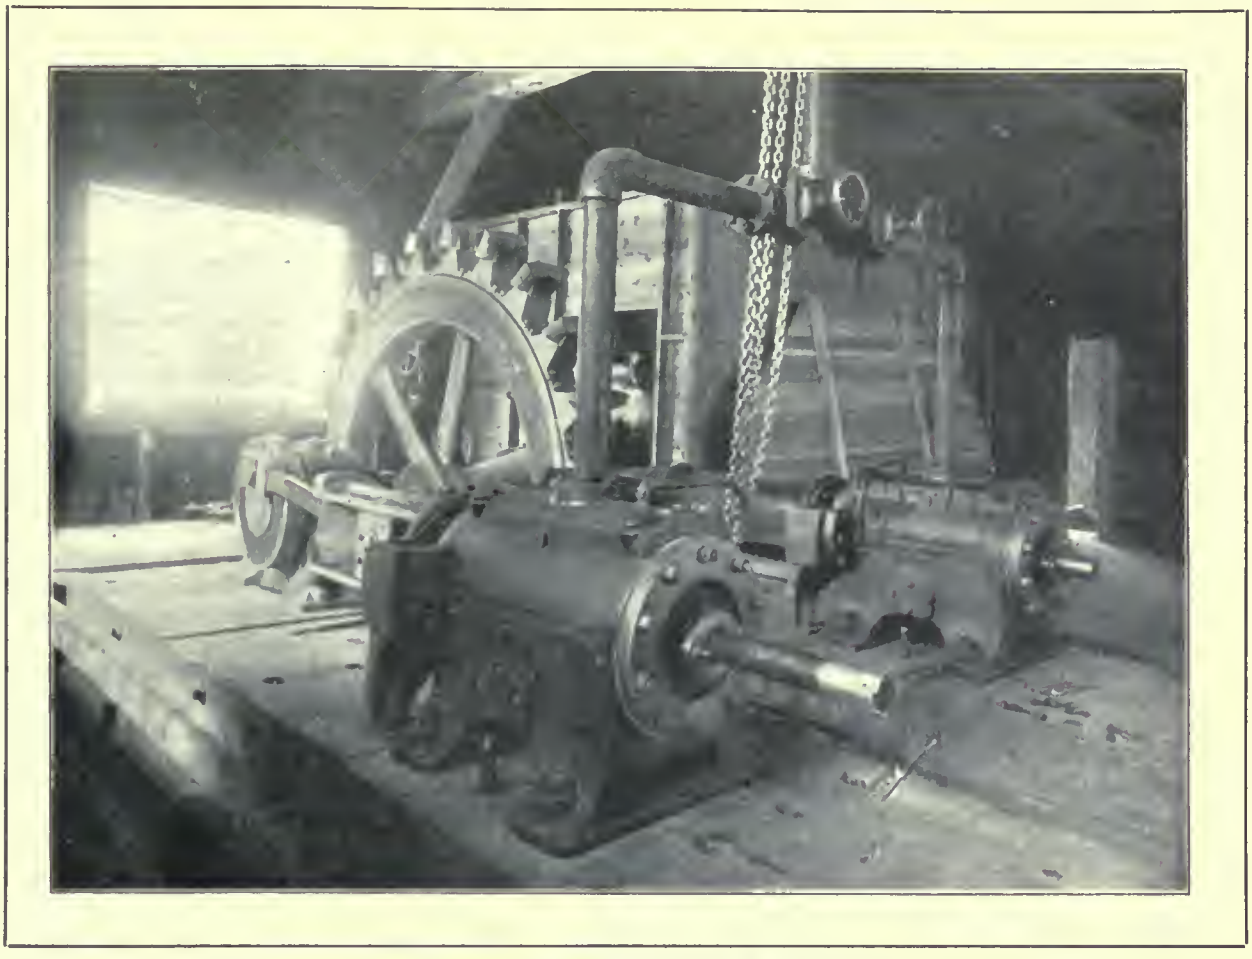
By taking out the steam cylinders, the floor space could be reduced to 15 by 12 ft. The ground was excavated for 8 ft. Boulders and rubble were tamped down for a thickness of 2 ft., and then a solid block of re-enforced concrete 28 in. thick was put down over the whole bottom. In this concrete were used 5000 lb. cement, 20 tons of freshly broken rock and fine gravel, and 22 12-lb. steel T rails laid cross-wise, the bottom row holding down the anchor bolts. The concrete was allowed to set three weeks before the solid timber foundations for the two sides of the compressor were built up. These timber foundations were each made of 16 pieces of 12 by 12 by 15-in. pine, keyed and bolted together with 1-in. bolts.

The steam cylinders were replaced by castings, shown in the photographs on the opposite page, by which the guide-frames were connected to the air-cylinders, allowing a space of 8 in. between them, and the air-cylinder piston-rod was connected to the cross-head by a short piece of 2½-in. rod just sufficient to bridge this space.

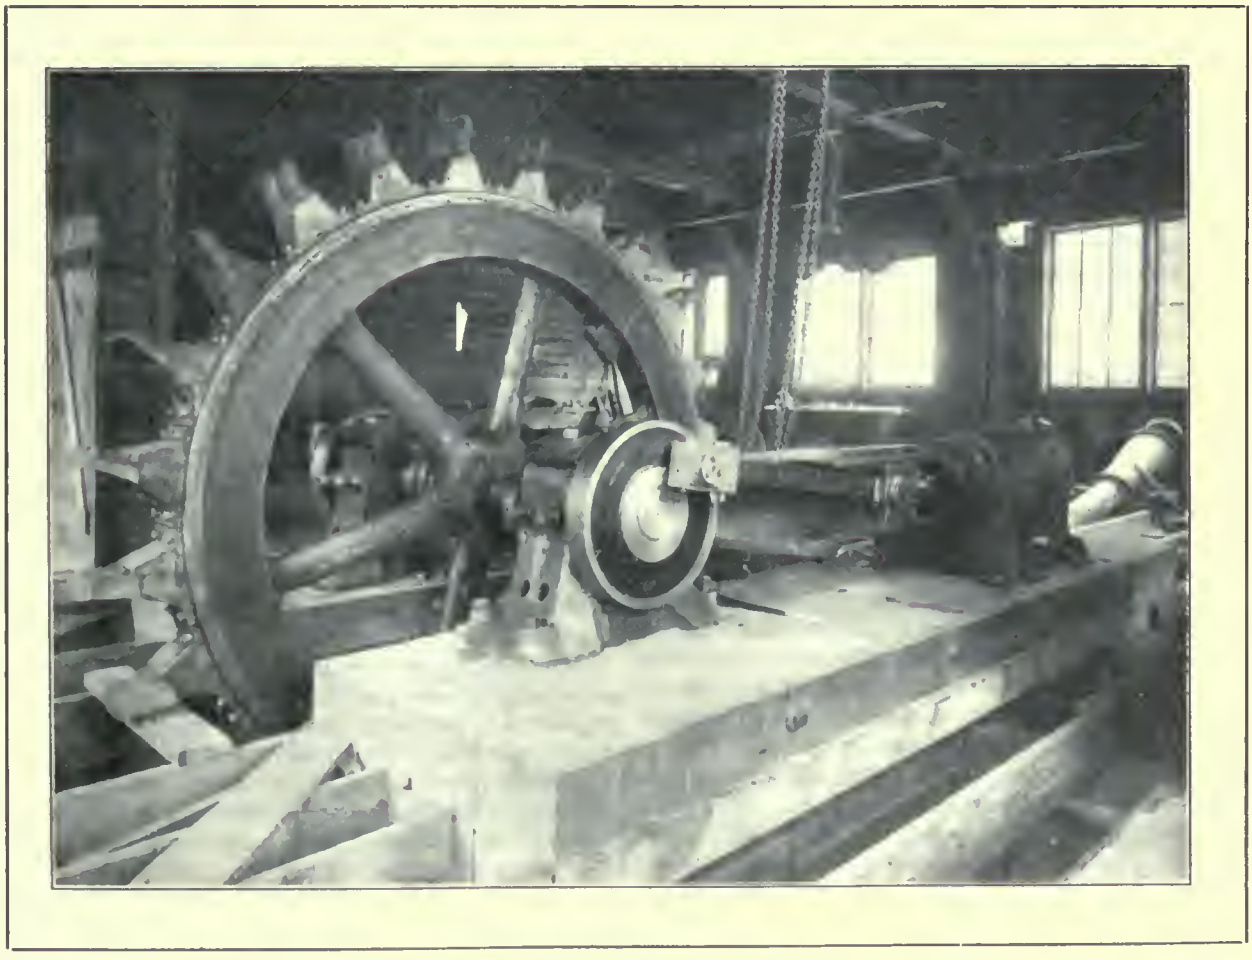
The fly-wheel diameter was 99 in. The diameter of a water-wheel required to satisfy the conditions of 315-ft. head and 120 rev. per min. being 124 in., the difference was made up by casting the buckets with webs or feet that interlocked in the manner shown, forming a continuous band round the fly-wheel, and the attachment was by means of four ⅝-in. cap-screws to each bucket. Each bucket weighed 39 pounds.

The compressor has now been running six months with perfect satisfaction. Efficiency trials have been made from which the following data have been collected: Head of water 315 ft., flow of water 290 cu. ft. per min.; horsepower of water, 147; revolutions per min., 123; M. E. P., 35.87 lb.; piston area, 152.88 sq. in.; stroke, 1.5 ft.; I. H. P., 122.65; efficiency, 83%. Every care was taken in making these trials and there is no doubt that one or two points were lost owing to the somewhat worn condition of the cylinders.

Tellurium and Gold.—It is now a matter of common knowledge that the volatilization loss in the roasting of telluride ores is not heavy. In every careful experiment the amount of gold sublimed has been found to be practically nothing.—T. K. ROSE.



Steam-Compressor Adapted for Use With Water-Power.



A Fly-Wheel Transformed Into a Water-Wheel.

MILLING IN THE COEUR D'ALENE.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE HUSTON.

The type of mill used in this district takes into consideration only one property of the ore treated, that of specific gravity. The softness of the commercial metal is a factor entirely neglected, and to this property is due most of the loss incurred in concentration. Not all of the so-called slime is due to the mill machinery; a good portion is already reduced to a slime before reaching the mill.

The veins are large. Overhead stoping is the rule, machine-drills, long holes and heavy charges, deep chutes, and rough handling between the mine and the mill are the usual methods; no wonder so much fine stuff is made. The mining methods may be unavoidable, but the subsequent mill treatment shows that the factor of abrasion and the treatment of the fine resulting from rough handling, were completely overlooked in designing the head end of the ore-dressing plants. Hand-sorting obtains in some cases. The ore arrives at the mill in sizes ranging from lumps 12 inches in diameter to impalpable galena dust, the latter due to the tremendous force of explosives on the soft sulphide of lead. Assuming that the handling in transit is unavoidable, we find on examination under a strong magnifier that the damp ore is coated with fine galena particles; in the lines of fracture the galena stands out boldly in sharp points on the harder material; abrasion has resulted in the creation of fine, from the pounding and friction of hard against soft material and the action of explosives. The harder portions have stood the ordeal comparatively unaffected, so that the fine is really the richest portion. At this juncture comes the crucial point in the milling of the Cœur d'Alene ore.

The prevailing practice is to pass the ore dry over grizzlies into the coarse-crushing machinery. From the bin it goes through the rolls and under the rolls receives its first dilution of water which is intensified by the meeting of the water carrying the middling from the coarse jigs, in process of elevation to the trommels. Further dilution occurs in the wash-water of the trommels. From this point the fine material with its water dilution is passed to the classifiers, or is led over a traveling belt-screen on the way to the concentrating machines. Abrasion has been intensified all the way through. The initial error consists in allowing this material to go through the abrasive action of the mill machinery, and subjecting it to the very large water dilution. This results in compelling a large installation of equipment, necessary to separate and treat a highly diluted product at the other end of the mill.

Good practice with soft ore indicates that no part of the product should be handled any more than necessary from the mill-head to the shipping-bin, in order to save abrasions and dilution. The part already sufficiently reduced in size should go direct to the concentrators. As for dilution, this should be kept at a minimum. The feed should be washed with water under high pressure through a small orifice to reduce this feature. The high pressure and small orifice should exercise a cutting action on the lumps and particles, just furnishing enough water to wash the material to the settler or belt-screen. The avoidance of abrasive apparatus in the mill equipment should be carefully studied and means provided below to remove the fine without allowing dilution to a greater extent than necessary.

Dilution compels installation of low-capacity machines such as the vanner and slime table, the handling over and over of the water and the large settling capacity so costly and such a prolific source of bother. Large slime losses are due to the error in trying to separate the fine at the wrong end of the plant. An ounce of prevention is worth a pound of cure.

Reverting to abrasion, I omit the trommel, a machine ruled out in good practice in Australia and Europe in favor of the shaking screen, and come to the jig treatment. Roughing or bull jigs are in use in every mill, regardless of the dissemination of metallics in the feed. In a finely disseminated feed, the bull jig is clearly out of place, as the coarse tailing still contains a considerable percentage of ore, which should be first re-ground. As an abrasive machine it is a bad example. A sample of mill-feed metallics taken from the bin before treatment, shows sharpness of angle and outline. The surface is rough. Samples taken from the cups of the bull jig, show the lumps, rounded and smooth. In an inspection of five cars of coarse concentrate at one of the large mines, all the lumps examined over 5 mm. in size showed the same rounded outline and smooth finish, indicating large losses. In three instances in the district the jig-water is caught and settled; in the majority of cases it washed into the tail-race.

A cure for this brings us back to the principle that there should be no unnecessary abrasion in handling and this would indicate that greater emphasis should be given to specific gravity on the jig-bed. The concentrate should be taken through the screen. In order to do this the screen-sieve should be of a larger perforation, and suction on the jig should be reduced or abolished in order to lessen the carrying down of waste particles into the clean concentrate. Suction on a coarse jig is out of place. It momentarily stops and starts the passage of the waste material. The specific gravity of coarse material is sufficient to settle the galena without the help of the back stroke of the plunger. Reducing the suction is accomplished by putting valve openings in the plunger. It is not within the limit of this article to treat further on abrasive action.

In a district treating approximately 5000 tons of ore per day, it is lamentable that no organized attempt has been made to bring out good practice for the common good through co-operation. Not a testing plant exists and defective sampling is responsible for the ignorance prevailing on what is really being done. It is hoped that the present article will stimulate discussion.

DRYING AIR FOR BLAST-FURNACES.—F. W. Harbord, a leading authority in England on iron and steel, describes in British patent No. 25112 of 1906 an interesting method of drying the air used in blast-furnaces. He uses a salt which takes up water of crystallization without deliquescing and which subsequently gives up its water at a comparatively low temperature. For this purpose he finds the sulphates of zinc, copper, or magnesium the most suitable. It has before now been proposed to use chlorides of calcium, magnesium, or other metals, but these more or less deliquesce and also tend to decompose on repeated dehydrations. In preparing the drying apparatus, porous material, such as common brick, is immersed in saturated solutions of the sulphate and so impregnated with the hydrated salt. The bricks are then built up into the drying chamber, and subjected to heating by means of hot air or some inert gas. The water of crystallization is thus driven off and the bricks are then ready for dealing with the blast as it comes from the blowing engine. In practice, the drying chambers will be arranged in pairs so that one is drying the blast while the other is having its water of crystallization removed by the hot air, and the pair of chambers will be fitted with suitable reversing valves.

MINING IN NEW ZEALAND.

Written for the MINING AND SCIENTIFIC PRESS
By an Occasional Contributor.

At Whangaroa, in North Auckland, there are copper-bearing lodes. An effort is now being made to work these, but the recent fall in the price of copper has had a discouraging effect. Whangarei is the principal centre of population in the North Auckland district. It is marked on the map on account of the Hikurangi, Komo, and Ngunguru coal-mines, which are in the adjoining district.

On the Hauraki peninsula, Coromandel is at present at a low ebb. A geological bulletin, by Fraser and Adams, is now in the press and will soon be available. At the Thames the rich patch in the Waiotahi mine, discovered about the end of 1904, is now nearly exhausted. For some time this yielded bullion at the rate of £18,000 to £19,000 per month, but the monthly output is now reduced to about £9,000, and will probably soon be much less. No other Thames mine is doing much in the way of gold getting.

At Karangahake, the Talisman mine is doing very well, the monthly output being about £15,000 to £16,000. The ore averages £1 per ton. The Crown is hardly paying its way, with a monthly output of £4,000 to £5,000, the ore averaging about £2 per ton. The Waihi mine is maintaining a monthly output of £60,000 to £65,000. The September yield will bring the total return to over £6,000,000. Its neighbor, the Grand Junction, has a monthly output of £4,500 to £5,000 from 10 stamps, but has not yet reached the dividend stage.

In the Te Aroha district very little mining is going on and at present there is hardly any gold production. Near Gisborne there are indications of oil, and some prospecting has been lately done. Some of the people there are pressing for a geological survey of the oil-bearing country. They want the anticlines mapped.

At New Plymouth there has been considerable excitement within the last year owing to a good flow of oil having been struck in one of the bores at Moturoa (two miles away). A few barrels of crude oil have been sold, but at present the bore is sealed. New Plymouth may be regarded also as the centre of the future 'iron sand' industry of New Zealand.

In the neighborhood of Woodville the Maharahara Copper Co. is reported to be developing a large copper-bearing lode, but lately we have not heard much about this property. The Mokau river, north of New Plymouth, gives access to a large coal-bearing area. At present one mine is operating. The principal coal-bearing district of the North Island, the Waikato, about 40 to 50 miles south of Auckland has not been marked on the map. The chief townships here are Huntly and Taupiri.

Picton is near an alluvial gold-mining district, Wakamarina, which is now no longer prominent. Antimony ore has been worked at Endeavour inlet, a bay off Queen Charlotte sound. South of Nelson is a copper-bearing district, where the United Copper Co. is now operating. They have shipped a few tons of ore to Sydney. Collingwood is the port of a well known mineral district. Undoubtedly the chief mineral resource of this place is the Parapara iron ore (see N. Z. Geol. Bull. No. 3 lately published). A company to work the iron deposits with a capital of £600,000 has just been underwritten at London. The ore is there in almost unlimited quantities, and the quality is good. Most of the conditions required for success are present, but it remains to be seen whether at the present time it is possible to compete with British manufacturers for the Australian trade, on which success must depend; for I think the population of New Zealand is as yet too small to keep a really big iron concern going, even though the Parapara Iron Co. should succeed in obtaining all the New Zealand orders by means of a heavy protective duty, which it will no doubt promptly demand.

Westport is the principal outlet of New Zealand's finest coalfield. Greymouth is also a coal-exporting port, as well as the centre of an alluvial gold mining district. It is a flourishing town. Reefton is the centre of an extensive vein-quartz district. The principal mines are under the control of the Consolidated Goldfields Co., an English concern. The gold output of £10,000 to £12,000 per month is at present inclined to decrease, but the English company is developing a new mine, the Blackwater, which is expected to turn out well. Hokitika is now almost completely shorn of its ancient glory, and is supported more by timber and agriculture than by alluvial gold mining. Present population about 2,000. Ross is in a similar state of decadence. One alluvial claim, the Mont d'Or, is still yielding well.

Kaitangata is marked on the map as the chief coal-mining centre in Otago. Orepuki has coal in its neighborhood, as well as alluvial gold (and a little platinum).

Dredging has had a great vogue in New Zealand, but its day seems to be passing. The amount of ordinary alluvial mining is slowly decreasing, and gold-vein mining is even deader than it was ten years ago.

THE production of Nevada in 1907 is estimated at $15,000,000 of gold and 6,000,000 oz. silver.

THE BOSTON CONSOLIDATED MILL.

STAFF CORRESPONDENCE.

The new mill of the Boston Con. M. Co., situated at Garfield, 15 miles west of Salt Lake City, is practically complete, with three of its 13 sections in operation. The main building, crude-ore bins, and machine-shop are built of structural steel and the transformer building is of brick and concrete. The machine-shop is modern as to arrangement and equipment and is prepared to manufacture ore-cars and to cast shoes and dies, as well as do all kinds of repairing that this company may require. The ore-bins occupy a building 300 ft. long and have a capacity of 15,000 tons of ore. The mill-building is erected on concrete foundations, lying upon the northerly slope of the Oquirrh range, facing the lake, the surface inclination being such as to favor the arrangement of the machinery for automatic work.

The machinery installation is in 13 sections, each of which contains 24 Nissen stamps, 4 classifiers, 24 Callow cone-settlers, 18 Johnson vanners, with an interesting system of launders and distributers for conveying the classified material in accordance with a well-designed plan. By tracing the material from the ore-bins to the final re-treatment process, it will be seen that there are no elevators in the mill, and that the movement of the ore through the various stages of the process is by force of gravity, with the exception of a belt-conveyor, operating at a 20° incline, which conveys the ore from the crusher floor to another conveyor that distributes to the battery-bins.

The ore is delivered to the crude-ore bins from self-dumping railroad-cars. From the bins the ore is fed through ratchet link-belt gates to heavy belt-conveyors, which deliver it to two (style K) gyratory crushers, and these reduce it to a 4-in. ring. It passes thence to revolving screens of manganese steel, having 1¼-in. opening. The material passing through these screens is ready for the stamps, but the oversize is re-crushed to 1¼ in. by two (style K) short-head crushers. The ore, after being reduced to this size, is delivered to the incline belt-conveyor, above referred to, which discharges upon a second conveyor, the latter being equipped with a 'tripper' by which the ore is distributed to the various bins above the stamps. From the bins the ore is drawn automatically into Challenge feeders, of which there is one feeder for each of the 312 stamps. These stamps, weighing 1500 lb. each, crush the ore through 28-mesh screens of No. 28 wire cloth. Each stamp drops into an independent mortar and is estimated to perform a duty of between 9 and 10 tons per day. The pulp from the mortars passes to a system of hydraulic classifiers, the overflow from which passes to Callow cone-settlers, which make four sizes, each size discharging upon a Wilfley table. The first product of the classifiers, of each section, is fed to six Wilfley tables, which make a concentrate, middling, and tailing, the headwaters being re-treated over Johnson vanners. The second product of the classifiers is treated like the first, and the third size of each section is handled by six Wilfleys which produce a concentrate and middling, but no finished tailing, the middling being re-treated over the vanners. The slime-settling syphoned from the Callow tanks is concentrated by four Wilfley tables for each section, and all this material except the concentrate is re-settled and re-concentrated over vanners.

All the concentrate produced passes to one launder for each section and all these converge into one main launder, which conveys the concentrate several hundred feet into five re-enforced concrete bins, where it is settled, the water drawn off, and the concentrate loaded into cars by a clam-shell bucket, manipulated by a locomotive crane. The final tailing is conveyed to a waste basin on the desert by means of a main launder that receives the tailing from all sections of the mill. All overflow water from the Callow settlers is pumped to the reservoir above the mill for use again. The water for the mill is conveyed by a pipe-line from springs eight miles away to a pump-station in the valley near the mill, where two turbine electric pumps lift the water 380 ft. to the reservoir above the mill.

The concentrate is a clean product, representing a reduction of 15 to 20 tons to one ton, from an ore carrying 1.4 to 2% copper and $2 to $3 in gold and silver per ton. This ore, mined at the Boston Con. properties in Bingham canyon, is said to be uniform as to assay-value and occurs in a porphyritic gangue, having chalcopyrite, bornite, and chalcocite finely disseminated through it. A. J. Bettles, mill manager, who designed and supervised the construction of the mill, states that the machinery is giving most satisfactory service, and that the plant is making a higher extraction than he had estimated. All machinery is operated by electric power transmitted from the power-plants at Ogden and Provo. The transformer plant at the mill has facilities for receiving currents at 80,000 volts and reducing to 400 volts. The electric apparatus at the mill sub-station and in the mill are of the Westinghouse type.

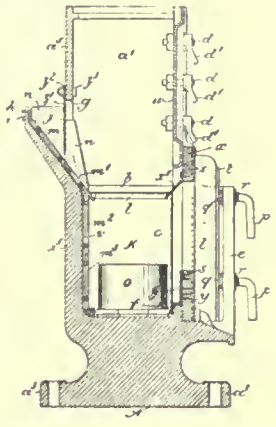
It may be further stated, to make the description complete, that the battery posts are of wood and the mortar blocks are of concrete deeply set. The stamps are installed in two parallel rows, 30 ft. apart, back to back, the chutes from the ore-bins leading to the stamps on both sides. While only three sections are now operating, it is stated that the others are nearly ready for work and will gradually be brought into service.

Earthquake shocks which have caused the shutting down of the Glendon mines, owned by the Wharton Steel Co. at Hibernia, N. J., are believed to indicate that the entire mountain range in which the mines are situated, extending through Morris county from northwest to southeast, is undergoing a settling process. The shocks have caused the cracking of the rock formation in the mine and caused the blocking of the adit leading to the workings, forcing the stoppage of operations. The shocks, it is said, have been felt at intervals for almost twenty years.

MINING AND METALLURGICAL PATENTS.

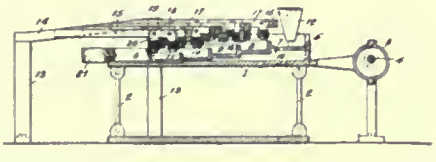
Specially Reported for the MINING AND SCIENTIFIC PRESS.

MORTAR-BOX FOR STAMP-MILLS.—No. 877,291; David A. Bremner, London, England.



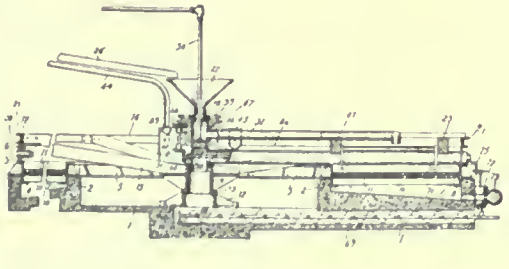
In a stamp-mill having a series of stamps, a mortar-box with a screen opening at the front and solid ends comprising front portions the internal surfaces of which are perpendicular to the back wall and intermediate portions having concave internal surfaces curved to a radius approximately equal to the distance between the center of the adjacent end stamp and the back wall of the box, said curved and perpendicular surfaces being adapted to guide the pulp round the end stamps and toward the front of the box, as set forth.

MAGNETIC SEPARATOR.—No. 871,301; Alfred Schwarz, New York, New York.



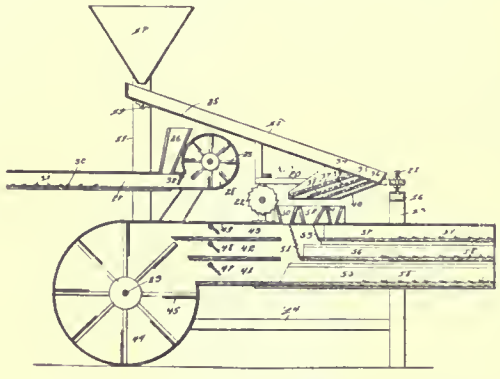
In a magnetic separator the combination of a table subdivided by riffles adapted to prevent transverse gravital flow of the material fed thereto, electro-magnets above and having their polar faces in proximity to said table, said magnets being disposed in independent rows, means to feed the material to be separated in proximity to the first row of magnets, means to energize and deënergize said rows of magnets successively to separate a given mass of magnetic particles from the nonmagnetic and to transport the former from riffle to riffle in response to magnetic attraction, and means to receive the separated masses.

CONTINUOUS FILTER FOR CYANIDING, AND THE LIKE.—No. 877,197; Bertram Hunt, San Francisco, California.



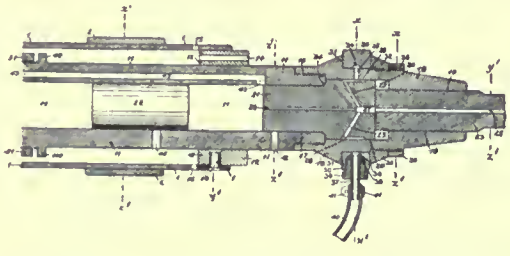
A filter comprising a stationary filter bed, a feeder movable over said bed for distributing thereover the material to be filtered, a scraper also movable over said bed for removing the residual material, and means for moving said feeder and scraper over said bed, substantially as described.

ORE-SEPARATOR.—No. 877,411; Aaron Custer, Monroe, Iowa; John Custer administrator of said Aaron Custer, deceased.



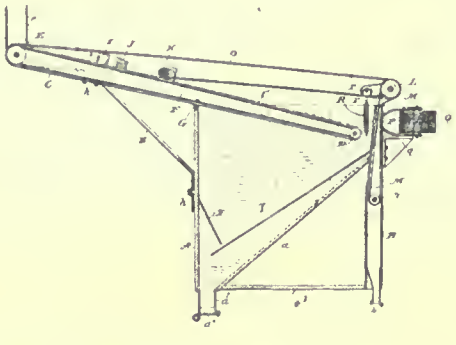
In an ore-separator, a suitable frame, a plurality of flumes horizontally mounted on said frame, screens extending down in the upper flumes, blast mechanism communicating with said flumes, feeding mechanism communicating with said flumes, and jigging mechanism acting on said feeding mechanism.

ROCK-DRILLING MACHINE OR ENGINE.—No. 872,417; Henry Hellman and Lewis C. Bayles, Johannesburg, Transvaal.



In a drilling or boring machine or engine actuated by fluid pressure, in combination, a casing, a hollow or tubular piece slidingly and non-rotatably carried by said casing, a head or tool-holding device revolubly attached to the forward end of said tubular piece inside the casing, a drill or tool operatively carried therein, packing located in the casing between the exterior of said tubular piece and the interior of the casing, means for introducing the actuating fluid to the casing at the rear of said packing to feed the drill, a piston in the tubular piece, means operated by the piston for transmitting to the revoluble piece and drill or bit an intermittent rotary motion in one direction, and means for admitting the fluid to reciprocate said piston.

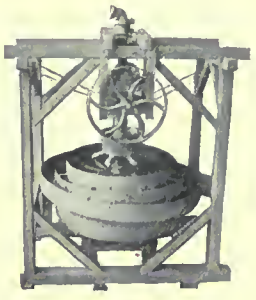
APPARATUS FOR MAGNETICALLY CONCENTRATING ORES.—No. 877,439; Henry Leighton, Seattle, Washington.



In a magnetic separator for treating materials in a wet state, a receptacle adapted to contain water, a magnet, means for feeding the material into the water into the magnetic field, and means interposed between the end of the feeder and the magnet in the direct path of the material for agitating the water between the discharge end of the feed and the magnet.

The Schutz Separator.

This machine is constructed with a view to concentrating the valuable minerals from mill-pulp, river gravel, or beach-sand, utilizing the principle of hydraulic classification with a number of important innovations. In the classifiers now generally used the water intended to force the lighter particles upward is introduced through a fixed aperture,

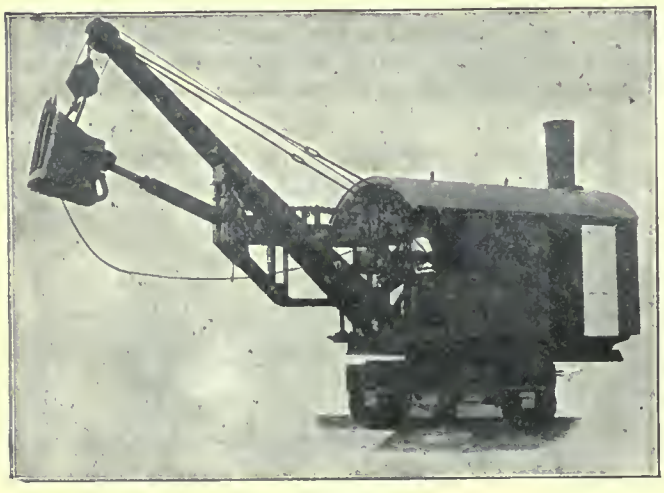


and from experience it has been found that the upward force of the water is not effective over the entire area of the hopper into which the pulp is passing. Mr. Schutz has overcome this defect by introducing the water through perforated pipes revolving on the bottom of a cylindrical hopper.

The hopper is fitted with two sets of submerged revolving metal brushes through which the pulp must pass. The brushes have the effect of cleaning and separating the particles. The hopper is constructed with an inner and outer shell, the space between the two shells forming the means of exit for the tailing. The machine is capable of large capacity. A 6-ft. machine with power attached is on exhibition at 471 McAllister St., San Francisco, and the Schutz Separator Co., owner of the patents, is prepared to treat samples of 50 to 100 lb. on a working model set up at the above address.

Thew Shovel for Electrical Operation.

It is frequently desirable to make use of power-shovels under conditions that preclude the use of steam. Where fuel or water are not available or for operation in tunnels, underground mines, or confined spaces, it is at times possible to substitute electrical power. For such requirements the engines and boilers of the standard machines are



replaced by electrical motors of suitable design. Any one of the varied forms of current in commercial use can be adapted to service of this nature and we are prepared to equip any of our single-truck shovels for electrical operation. For such installations, the motors are of the most approved type, of ample power and especially adapted to the requirements, which are both peculiar and severe. The current is preferably received through contact rings on the truck-frame, to which are connected flexible cables from the feed-line. The current is transmitted through carbon brushes, suitably attached to the turntable or revolving portion of the shovel. The wiring, switches, circuit breakers, controllers, and all necessary adjuncts conform to the most approved methods. Experience has shown the most desirable equipment for direct-current installation to comprise two motors, the swinging motion being controlled by frictions from the hoisting motor. Where alternating current is employed a single motor operating at constant speed is recommended, all motions being controlled through friction clutches. The absence of the boiler and water-tank necessitates the use of a counterweight to secure proper stability for the machine. The fireman, usually required for rated capacities, is not needed where the electrical design is employed and the shovel becomes a strictly one-man machine. Further information can be obtained from the Thew Automatic Shovel Co., of Lorain, Ohio.

Books Received.

'Mining Investments and How to Judge Them' and 'The Investor's Primer' are two new books likely to be in demand at this time, when the whole question of investment is so much in the minds of people. These books are by John Moody. The first is an attractive handbook covering, in an entertaining manner, the whole subject of mining investments and the values of stocks The author is said to be a man of wide experience The second volume discusses the general question of investment, it gives in a clear and concise manner the definitions of important terms and phrases used in the banking and investment business, and a description of the methods involved. Each book sells for $1.50 and is obtainable through the MINING AND SCIENTIFIC PRESS.

'The California Earthquake of 1906.' Edited by David Starr Jordan. Published by A. M. Robertson, San Francisco. 360 pages. Price $3.50. This attractive volume includes two papers by the President of Stanford University and by G. K. Gilbert, reprinted from *Popular Science Monthly;* it contains a new essay by Charles Derleth, of the University of California, besides three other papers, and finally a sketch of personal experiences by Mary Austin. The book is well illustrated and well printed. Within convenient limits it affords information concerning the various features of the earthquake, from the geological to the structural, and from the purely scientific to the intensely human aspects of the disaster that overwhelmed San Francisco and the neighboring towns. We have had a good deal of earthquake literature and this represents some of the best of it.

SCHOOL OF MINES OF THE PENNSYLVANIA STATE COLLEGE.—The last legislature of Pennsylvania appropriated $50,000 for this School, of which sum $20,000 was for further extension of its buildings and $30,000 for maintenance. The buildings, as planned and partly built and occupied, contain over 60,000 sq. ft. of floor space. The buildings contain laboratories and lecture-rooms, for the instruction in crystallography, mineralogy, petrography, geology, mining geology, metallography, metallurgy, assaying, ore dressing, coal washing, mining, etc. Among the recent appointments are these: Clarence P. Linville, Assistant Professor of Metallurgy; Frank A. Dalburg, Instructor in Mining and Metallurgy; Lloyd B. Smith, Instructor in Mineralogy and Geology; and Howard I. Smith, Instructor in Mineralogy and Metallurgy. The summer school in Surveying and Mining was conducted at Canonsburg, Pa., in the mines of the Buffalo & Pittsburgh Coal Co., under the direction of Messrs. Dalburg and Smith. Later a large party of students spent the remainder of the summer at the mines of the Nippising Co., at Cobalt, Ontario. The class graduating from the School, in 1907, numbered 26 men.

THE A. S. CAMERON STEAM PUMP WORKS of New York now has ready for distribution its catalogue No. 35. It is probably one of the most complete pump catalogues ever published and contains much useful information for pumpmen and engineers.

Editorial.

IN ORDER TO prevent any misunderstanding of the attitude assumed by the officers of the Geological Survey in relation to the proposed Mining Bureau, our readers are invited to read the letter of the Director, Mr. George Otis Smith, appearing on another page of this issue.

NEW IDEAS on the theory of ore deposition are always interesting, especially when they are offered by experienced geologists. Our readers will be glad to study the contribution from Mr. J. E. Spurr appearing in this issue. Mr. Spurr is the author of 'Geology Applied to Mining,' a handbook much in demand among those who are engaged in mining whether as operators or engineers, and by his experience, first as an officer of the Survey and then as a specialist employed by the Guggenheims, he is particularly fitted to throw light on the dark places of ore deposition.

REFERRING TO the State Mining Bureau, the administration of which we criticized in these columns recently, we note that the executive committee of the California Miners' Association at its last meeting unanimously passed a resolution as follows:

"Resolved, by the executive committee of the California Miners' Association that said committee has learned with extreme regret and deep indignation that Mr. Chas. G. Yale has been removed from his position as Statistician in the State Mining Bureau:

"That in the opinion of said committee no other man in the State can so efficiently fill said position as said Charles G. Yale, and that his removal is a detriment to the usefulness of the California State Mining Bureau, and to the mining interests of California, and we hereby desire to voice our emphatic protest against this action.

"Resolved, that a copy of these resolutions be certified by the secretary of this committee and be sent to the Governor of the State, to the State Mineralogist, and to each member of the Board of Trustees of the California State Mining Bureau."

The persons to be held responsible are the Trustees. They can refuse to confirm the new appointment of Mr. Yale's successor. We look to them to act in the public interest.

AMONG THE OPPORTUNITIES of becoming rich quickly is that offered by the Nome Gold Dredging and Power Company, concerning which some astonishing things are said in circulars now being sent broadcast. "This proposition will pay dividends of 100 per cent per annum," it is "one of

the most profitable enterprises known to mankind," and it has gold "sufficient to pay an average of 100 per cent annually for over 44 years to every stockholder." Among the officers of this benevolent enterprise is the "Hon. William J. Stone, Jefferson City, Missouri, United States Senator from Missouri, and former Governor of that State." Is he so poor as to have to sell his name for boosting a scheme concerning the merits of which he is no judge, a scheme that on the face of it is a rank imposture, or is he simply dis-honorable? It is time for public men to know that they can be held to account for lending their names to irresponsible promoters, for exchanging what they possess of honor for a block of stock, for using public office as a lure to the unwary.

DIVIDENDS paid by companies operating the gold mines of the Transvaal amounted to £7,131,608 or $34,588,298 for the year 1907. Forty-five companies out of 65 productive mines contributed to this total, the increase over 1906 being £1,396,443. It is estimated the profits earned by the mines of the Rand in 1907 was £10,000,000, or nearly $50,000,000, on a gross production of £27,403,728.

Rawhide, Nevada.

RAWHIDE is the scene of the latest mining excitement in Nevada. This new camp is in Esmeralda county, about 25 miles east of the upper end of Walker lake, 45 miles by stage from Luning, 54 miles by automobile from Mina, 30 miles by automobile and stage from Schurz, and about 50 miles south of Fallon. At the present moment there is a tremendous rush of gold-seekers toward this new El Dorado, and it is likely that the general stagnation of other forms of business enterprise will stimulate an unprecedented boom even in a region that has seen so many episodes of the same kind. We learn from Mr. Algernon Del Mar, who is our representative at Rawhide, that the ore is a quartz-porphyry containing free gold in association with pyrite; the veins are wide and the general character of the formation resembles that of Camp Rochester, near Ludlow, in San Bernardino county, California. Some of the ore is undoubtedly rich, but the evidence available at this early date indicates that the future of Rawhide will depend on the ore milled on the spot, that is, not much of it is rich enough to be shipped to the smelters. This means that systematic work will be necessary, capital must be invested under proper advice, and the productive character of the district will not be made apparent right off. The times change, and we with them; nowadays a mining boom springs into life full-fledged, with tail feathers and a triumphant shriek enough to awake the seven sleepers of fable. Distance is vanquished by automobiles, the telegraph is the herald of mineral discovery, newspapers and saloons are at work almost with the first blow of the pick, and the real estate speculator follows hard on the heels of the prospector. Let us be hopeful that this new scene of mining activity will be another of the successes scored by Nevada during recent years, but let us remember that gold mines are not made by much shouting. In the meanwhile, if you have spare time and a few dollars that you can afford to lose, go and see Rawhide for yourself.

By-Laws of the Institution.

NOTICE has been given of a special meeting of the members of the Institution of Mining and Metallurgy, to be held at London on March 18, for the purpose of voting upon some changes in the by-laws. We note with interest that besides the old regulations (as to a candidate for membership being 30 years of age, occupied in practical mining or metallurgical work, and for at least five years in a responsible position thereto), it is now provided that the candidate may gain election if in the opinion of the Council he is a desirable person to become a member, by reason of his position or attainments. This amendment was undoubtedly proposed with an eye to the dilemma created by the fact that in times past one or two engineers not yet 30 years old and yet occupying positions of great responsibility have been ineligible for membership although ranking high in the profession. For instance, it is not invidious to say that both Messrs. H. C. Hoover and A. C. Beatty were doing important work and carrying heavy responsibilities successfully before they were 30 years old. Capacity for work is not measured in terms of the calendar. Next we note that candidates for admission as associates of the Institution must be 25 years old and shall have been engaged in practical work for a period of **two** years if graduates from a recognized School of Mines; if not so graduated, then **four** years is the time specified. This is a significant and logical recognition of the particular value of a special training, namely, it facilitates the attainment of practical knowledge. Many men who never went to a School of Mines have proved themselves among the best engineers in the world, and some men who graduated with scholastic honors have been failures in the wider arena of life, but it is certain that as a rule the special technical training enables a young man to learn more quickly and more systematically—that is the demonstrated theory underlying the whole idea of technical education. The Council recognizes it. Finally, it is proposed to increase the dues from all classes of members. Full members elected after December 31, 1908, will pay three guineas or $15, instead of two guineas or $10. This is an important departure and we applaud the courage of the Council in choosing this method of increasing the income of the Institution. Within the last three or four years it has become apparent to the officers of the Institution at London and to those of the Institute at New York, that the expenses of publishing the transactions, in pamphlet and volume, together with the growing cost of administration, were gaining upon the revenue. To both societies there came the temptation to sell advertising space in their bulletins; the Institute yielded to the temptation; the Institution set it aside as bad form. The alternative was to increase the dues; the Institute deemed it

inadvisable; the Institution has adopted the plan, which will now go into effect. We hope, and believe, that this method of raising the necessary funds will be a success. If it is, then our Institute in New York will have an excellent object lesson, for if higher dues prove acceptable in England they ought to be so in America, where the cost of living is so much higher as to make $15 seem a good deal less than £3. On the whole, these changes in the by-laws will tend further to establish the claims of the Institution upon the confidence of the English-speaking members of the mining profession.

Copper Production.

THE LARGE SURPLUS of copper, estimated at 200,000,000 pounds in October, has been cut down to less than 70,000,000 pounds and there is said to be a healthy demand for the metal in Europe. Mr. James Douglas states that "the consumers are anticipating an advance in price in the near future," but other reports suggest unusual apathy on the part of American consumers, despite the diminution in the stock of metal. Undoubtedly, the copper market is sensitive to the threat of the forthcoming commencement of production on a large scale from two or three mines in Nevada and Utah. The Utah Copper Company at Bingham is now producing at the rate of 3,500,000 pounds per month, the yield being 1¼ per cent. It is estimated that the concentrators of this company will, within a few months, be turning out 55 to 60 million pounds of copper per annum at a cost of 8 cents per pound, delivered at New York. The Boston Consolidated, in the same district of Utah, has made a good start and is ready to produce about 35 million pounds per annum at a cost of 9 cents per pound of copper. Finally, the Nevada Consolidated and Cumberland & Ely mines will soon be sending their ore to the new Steptoe plant and after May next the output is expected to be 35 to 40 million pounds of copper, from ore averaging 2¼ per cent. Eventually the Steptoe concentrator and smelter are to have a capacity of 60 million pounds per annum and all this copper will be delivered on the New York market for a total cost of 8 cents per pound. Moreover, the Cerro de Pasco mine, controlled by James B. Haggin and the Hearst estate, is beginning to produce copper, after 10 years of preparatory work. In 1907 this property yielded 20,152,000 pounds of copper, all of which was refined at Baltimore. In 1908 the production is to be 30 million pounds, and it is predicted that a maximum of 50 or even 75 million pounds is likely. Up to the present no less than $17,500,000 has been spent in equipment and development. Finally, the ore deposits of the Tanganyika Concessions Ltd., in central Africa, are destined to influence the copper market as soon as the railroad, now under construction, is completed and reduction works are built. This source of copper is yet in reserve, but it is likely to influence the market four or five years hence; so also are the new districts of the Copper River, in Alaska. No wonder the operators of copper mines, no less than the metal brokers, are in a state of anxiety, for all this cheap copper makes it so much harder for the old mines to win a profit, because the prolific production of these new enterprises will tax the capacity of the market.

In copper mining, as in the cosmos, it has become a struggle to survive and the fittest to survive is the mine that operates under the largest margin of profit. Of the older mines, the Calumet & Hecla with an 8½ cent cost, or the Osceola with 10½ cents, is in a strong position, but the Anaconda, which produces copper for 11.8 cents per pound has now a small margin, and the Greene-Cananea with an actual cost of 15 cents and a hoped-for reduction to 12½ cents, is in a decidedly weak position, as long as copper hovers around 13 and 14 cents. The special report of the Census Bureau gives some interesting figures in regard to the cost of copper in 1905; for instance, the gross cost in Michigan is given as 11.4 cents for refined copper, and in Montana 11.6, after the gold and silver are deducted. In Utah blister copper cost 15.5, or 5.5 when the value of the precious metals is deducted; in Arizona the figures were 8.3 and 7.5; in California 9.8 and 6.2 cents; to these figures 1½ to 2 cents must be added for transport, refining, and marketing. This was over two years ago; as conditions are now the total cost is nearly two cents higher all round, by reason of the rise in wages, scarcity of fuel, increased expenses of living, and so forth. Obviously the copper mine that does not also produce some gold and silver must either be abnormally rich in copper or must contain deposits, like the disseminated porphyry of Ely and Bingham, of vast extent, easily exploited.

The mines of the Boundary district of British Columbia during the year 1907 produced 35,500,000 pounds of copper at a cost ranging from 10¼ cents at the Granby to 14 cents at the Dominion mines, and at the present time, even with the help of the precious metals contained in the ore, any large production looks like exhaustion of resources without adequate profit. That certainly has been the characteristic of many copper enterprises during recent years; large sums of money have been expended in developing mines that never could give an adequate return on the capital invested, but they did produce lots of copper and spoiled the market, for to the consumer the metal that cost 15 cents looks exactly like that which cost only 10 cents to produce. The feline finance that inveigles the public into wild-cat gold mines may lead to the production of the precious metal at a cost of $100 per ounce, but the gold thus produced does not depress the price of the other gold that is dug out of profitable mines, which are being worked in a legitimate manner. The copper wild-cat, on the contrary, is a pole cat, for it produces unpleasant effects over a large area. The recent dehydration of the share market, especially as regards copper stocks, will discourage the organization of corporations to operate poor copper deposits and it may temporarily remove this one menace to the market. The publication of facts should check the flotation of undesirable ventures, while emphasizing the need of economy and skill in every kind of copper mining.

BY THE WAY.

In a recent issue of *The Evening Post*, New York, we find the following eminently sane comment on the recent unpleasantness:

Saturday's statement of the New York banks showed, for the first time since panic began with the Knickerbocker failure on October 22, a surplus over the 25% ratio of cash reserve to deposits required by law. In advance of this return to a surplus basis, the New York banks had resumed full cash payments to depositors; the currency premium had disappeared ten days ago; drafts on New York by banks of other cities are being met in cash; Chicago, Pittsburg, and Philadelphia banks are calling in for redemption the 'wage checks' issued during the currency famine. All this proves that the period of suspension of payments, complete or partial, is at an end.

With its habitual absorption in the future, the business community is now discussing nothing but the chances for or against a similar recovery in general trade. On this head, there is much to say; we shall at present, however, use the occasion rather to make some inquiry into the extraordinary episode which lies behind us. No doubt the most palatable comment would be congratulation to our financial institutions for having emerged from so formidable a crisis with relatively so little of outright insolvency. We shall not take this view. What, to our mind, stands out paramount in this panic episode is the refusal by the deposit institutions of this country during nine successive weeks, to return to its owners, on their request, the money deposited by them in trust with such institutions; the public sale at a discount during all this period, and in amounts running to the tens of millions, of certified checks on powerful and solvent banks, and, finally, the forcing upon wage-earners, by employers in half-a-dozen cities, of a makeshift currency not exchangeable for real money in the city of its issue and not receivable for payments in any other locality. Every one knows that this is a plain and accurate statement of what has happened; had such a state of things occurred in any other country than our own, our people would have described it as a shameful exhibition of weakness and bad faith. Why of all nations should the United States have been the scene of this extraordinary performance?

We are not among those who hold our currency system responsible. An ideal system—a central bank, an elastic currency—would no doubt have mitigated the after-effects of this break-down of credit; but we are convinced, along with the best European critics, that no currency system in the world would have stood up against such a raid on bank deposits as occurred in last October. But this merely shifts the inquiry to another question, why the money-hoarding mania should reach in this country, at such times, proportions never imagined elsewhere in the world, and why the various banking centres of the United States should stand out habitually as a dangerous menace to one another, the moment the American market falls into panic.

One explanation occasionally heard is that in affairs financial our people are impulsive, excitable, hysterical, and that just as they fling their savings into wildcat speculation during such speculative crazes as that of 1901, so, at a time of shaking credit, they see no recourse but to pull out their bank deposits and hide the cash. There may be some truth in this supposition. But the French are notoriously a more excitable people than our own, and they are, moreover, far more disposed to keeping their savings in the chimney-corner; yet nothing like this occurs in France. It must also be remembered that the practice of hoarding money, on the first signs of coming financial panic, has been directly encouraged by the experience of previous panics. The merchant, the small manufacturer, the dealer in land or produce, who remembered that in August, 1893, his bank refused for five weeks to allow him to draw from his deposit account the cash to pay his hands or consummate his purchases, cannot be wholly blamed if, in October, 1907, he is sorely tempted to get a supply of cash in hand before his bank shuts down on payments.

But if the trouble lies with the banks, what is it? Why should our fiduciary institutions be driven to this humiliating recourse, when it is never adopted elsewhere? We believe the simple and undeniable answer to be that our practice of redepositing bank reserves in banks of other cities, thereby diminishing the safeguard against deposits in the smaller cities, and entangling the banks of East and West with one another on a scale which no other community would dare to apply, creates a banking position which is certain to break down under strain of panic. Of the 6544 national banks in the field last autumn, 6178 were the so-called 'country banks' which by law are allowed to deposit with banks in other cities three-fifths of their 15% required reserve. Banks in the larger cities bid for these 'country-bank reserves' by paying interest on them. The result, as shown in the national bank reports just before the panic, was that, out of the reserve of these 6178 country banks, $420,000,000 was placed in more or less distant cities, and only $201,000,000 kept on hand in cash, where it could be used to meet, at a moment's notice, the demands of a run of depositors.

These figures seem to us to go far toward explaining the suspension of payments, the blockade of interior exchange, and the numerous resultant embarrassments, which mark such episodes as last October's. It will perhaps be rejoined that the Bank of England holds the reserves of others banks, precisely as do our larger banks in the 'reserve cities.' But the Bank of England maintains against such deposits a cash reserve, not of 25%, as in New York, but of 40% or over, and it furthermore would not dream of investing such funds in loans to Stock Exchange operators—the chief use which is made of them in New York. Our own belief is, that until these reserve provisions of the banking law are remodeled, or until the practice is modified by the banks themselves, the most perfect currency system in the world will not protect us, in the future, from repetition of such discreditable exhibitions as American banking has made of itself this winter.

Personal.

H. A. TITCOMB is in London.

JAS. W. ABBOTT is here from Pioche.

JOHN B. FARISH is at Globe, Arizona.

W. S. LECKY is with Mussens Ltd. at Montreal.

CURTIS H. LINDLEY has been at Redding this week.

ALBERT BURCH is examining mines near Tenabo, Nevada.

JAMES DOUGLAS has returned to New York from Arizona.

W. E. BURLINGAME, of Denver, was recently in Mexico City.

W. B. KEHOE, formerly at Ouray, Colorado, is at Boise, Idaho.

RODMAN SWIFT of Grass Valley spent a few days in San Francisco.

C. S. HERZIG has been examining mines at Bischofshofen, in Austria.

W. Q. WRIGHT returned this week from Goldfield to San Francisco.

GEORGE H. GARREY is examining mines at Taviche, in Oaxaca, Mexico.

ROBERT ARNOLD FOSTER is in San Francisco on his way to the Alaska Peninsula.

ALGERNON DEL MAR is visiting the new mining camps of Nevada. He is now at Rawhide.

W. H. BRYANT, formerly of Denver and now residing at Goldfield, is here for a few days.

J. R. FINLAY has returned to New York from a visit to the copper mines of Lake Superior.

ARTHUR AUSTIN, lately at Anaconda, is now with the Granby smelter, at Grand Forks, B. C.

BEN B. LAWRENCE is consulting engineer to the Nova Scotia Mining Co., operating at Cobalt, Ontario.

EDGAR RICKARD, business manager for the MINING AND SCIENTIFIC PRESS, is on his way to Chicago and New York.

A. A. HASSAN has severed his connection, as consulting engineer, with the Bishop Creek Gold Co., of Inyo county, California.

ALBION S. HOWE, BERTRAM HUNT and H. W. TURNER will have joint offices, although not partners, in the Mills Bdg., San Francisco.

W. ROWLAND COX has been appointed consulting engineer of the Inde Gold Mining Co. at Inde, Durango, Mexico; and is at present at the mines of the company.

ROBERT W. HUNT & CO. have established their St. Louis office, which is in charge of C. W. Gennet, Jr., at 1445 Syndicate Trust Bdg. They have arranged to place their chemical and cement laboratory in the same building.

FREDERICK W. BURRALL, superintendent of the Daly Judge mines at Park City, Utah, has resigned. He has accepted the management of a coal mining enterprise in Sweden which is backed by a syndicate of Boston capitalists.

ROBERT MCF. DOBLE, consulting and supervising engineer, making a specialty of hydro-electric power development and transmission, formerly of San Francisco, announces the removal of his office from Colorado Springs to 528 Majestic Bdg., Denver.

ROBERT H. RICHARDS has returned to Boston from Montana, where he has been installing some of his designs. He returned to his work of teaching at Massachusetts Institute of Technology, and to the further work on his third volume of 'Ore Dressing.'

ROYAL SCHOOL OF MINES.—The annual dinner of the past students in the Royal School of Mines will be held at the Hotel Cecil, London, on March 18, at 7 o'clock. The chair will be taken by Mr. Richard Pearce, Ph.D., Past President of the American Institute of Mining Engineers. Tickets can be obtained from the honorary secretary, Mr. George T. Holloway, 57 Chancery Lane, London W. C.

General Mining News.

ALASKA.

(Special Correspondence).—The President's message recommending "a simple form of local government," has been hailed with enthusiasm all over Alaska, but the ruling of the national committee, compelling the holding of another convention, is generally accepted as due to the influence of the Hoggatt-Whitehead-Guggenheim triumvirate, which was so severely checkmated by the friends of territorial government.——The scarcity of money is a serious handicap to Nome mining operators this year. It has been the custom of local financial institutions to assist mining operators in the development of paying properties, but little money is obtainable this year from the banks, no matter how gilt-edge the security.——A consignment of Cape Lisburne coal arrived in Nome on Dec. 10. It was freighted over the ice a distance of 600 miles in 16 days. Latest developments disclose three new veins of coal, which equals the best quality of that article imported from Seattle and British Columbia.——The usual complications over the surface and subterranean rights have begun in Nome, as in older mining camps, where the city was granted a patent for surface right and the miners also, to all privileges underneath the surface. The Nome-Smook Mining Co. has begun drilling at various points in the heart of the city (on lots owned by parties who live in the States), and driving in frozen ground under the principal buildings of the city is in progress. A continuation of the newly found submarine beach has been definitely traced at several points, a few hundred feet north of Main street, paralleling the sea-shore. This submarine beach was found last fall after navigation closed, and is known to extend from Nome river, underneath the heart of Nome's business centre, to Penny river, a distance of 10 miles. It lies on a clay bedrock about 25 ft. below sea-level, and is of uniform richness at all points where interrupted. The pay-streak in some places is over 125 to 150 ft. wide and 3 to 8 ft. thick. Fifteen cents per pan is claimed as a conservative estimate of its value.——A hundred feet north of the famous Bessie, Mable, Cyrus Noble, and Diamond L. mining claims, on the third beach pay-streak, another 'intermediate' beach deposit has been located that bids fair to rival all previous producers of beach-placer gold dust. Driving southward from the old workings of the third beach, on the same level, a series of 'mud horses' have been perforated that are lying on top of, and adjoining, rich beach concentrates. The knowledge of these conditions has stimulated unusually active prospecting.——John Bonnell, of the Nome Foundry & Iron Works, had his skull smashed to a jelly on Dec. 6. His brains protruded from the wounds, and pieces of his skull five inches long were removed. Strange to say, he is recovering.——First winter mail arrived in Nome by dog team from Seattle on Dec. 11, by way of Valdez and Fairbanks.——The tin mines of Lost river are working 15 men. The ore has improved considerably. Over a thousand feet of tunnels and drifts has disclosed big bodies of cassiterite ore, carrying tungsten, wolframite, galena and other by-products.——Nome and Seward Peninsula's coal product will be marketed at Tanana and Yukon points next summer. Big shipments will be sent to Siberia direct from the mines at tide-water on Norton bay.

Nome, Dec. 12.

Map of Alaska.

ARIZONA.

GRAHAM COUNTY.

At the Gold Belt mine near Clifton new machinery has been installed, and already the ore to a value of $202,000 has been blocked out or extracted. The shaft is down to 265 ft. and a cross-cut 150 ft. long has been driven to reach the main vein.——A contract has been let to drive an adit on the Gipsy mine at Morenci.——During the last two weeks some rich silver ore has been taken out of the Harper mine at Morenci.——The Arizona Copper Co. is receiving new consignments of machinery from the El Paso Foundry & Machine Co., which will be installed in the old smelter. The output of the smelter for January was 1441 lb. of blister copper.——The new camp of Stoddart is becoming important, owing to the high-grade ore being found in a new district. In the Binghamton mine a quantity of rich ore is developed, and the mines under development by the Copper Queen Gold Mining Co. are proving to be valuable. The shaft on the Binghamton is down 400 feet.

Rich copper ore has been struck in the Great Eastern mine at Globe, in three small stringers in quartzite formation.——Globe Cons. Co. continues development in the Gem mine and has driven a cross-cut 200 ft. long.——From the Malary shaft this company is hoisting some ore.——The shaft of the National Mining Exploration Co. has reached a depth of 500 ft., and the grade of ore is improving. It is reported that ore rich in copper and gold has been found on the Pinto claim, owned by H. Thomas.——Shipments have been made by the Big Spring Mining Co. from the Claire mine to the El Paso smelter.——At the Buffalo Hill mine a number of small veins carrying high-grade ore have been opened, but cross-cutting will be continued to reach a larger vein.

MOHAVE COUNTY.

The big strike of gold ore in the Richardson mine, near Union Pass, is said to be holding out well under continued development, and that many tons of rich ore are on the dump.——J. D. Spargo, who has a lease and bond on the Brown mine in the copper belt of Stockton Hill, has opened up a fine body of high-grade copper, gold, and silver ore.——Handsome specimens of gold in calcite have been taken by Thomas Lowell from a vein about 4 miles from the McCracken Hill mines.——J. E. Rose has been engaging teams to haul supplies and fuel to the hydraulic mine at Temple Bar.——C. W. Benedict is driving an adit to develop a body of good ore exposed in a shaft at a mine near Wallapai Springs.——In the cross-cut from the east drift

on the 100-ft. level of the Enterprise mine, a great body of ore is said to have been cut; it carries gold, silver, copper, and lead. A large part of the ore is of shipping grade, while the balance can be worked to a high-grade concentrate. W. A. Mensch is superintendent.——At the Gold Road mine several men are driving through the large body of ore recently found on the 700-ft. level; this ore is said to carry $28 per ton. At the Billy Bryan mine the three-compartment shaft is being sunk although the new hoisting plant and machine-drills are not yet in operation; J. De Salmard is superintendent.

YAVAPAI COUNTY.

(Special Correspondence).—W. F. Shaw and others are developing a promising group of claims on Wolf creek, in the Groom Creek district. Their claims are known as the Big Swede property. A tunnel is being run to tap the shaft, to drain a strong flow of water and also intersect the main lode.——The Empire mine and mill, another Groom Creek property, will soon resume operations on a larger scale than before. The mill is now making a test run, and ten additional stamps will be added as soon as it is determined just what is needed.——The great double-track adit being driven by the United Verde Copper Co., at Jerome, is now in about 3500 ft., and the drift from the 1000-ft. level is in about 600 ft. Work is not progressing rapidly, on account of the long haulage of waste, which is at present accomplished by the use of mules, but electric motors will soon be installed for that purpose.——A 32 hp. Morse & Fairbanks gasoline air-compressor is being installed at the Dillon tunnel of the Hull Copper Co. This tunnel is now in about 2700 ft. The drift from the '1888' claim is in 550 ft. and work is being pushed as rapidly as possible to connect it with the Dillon tunnel. G. W. Hull, president of the company, states that connection will be completed in about four months. He also states that their 50-ton smelter, which is already erected, will be blown in about May 1, 1908. An electric drill is expected from Denver, and will be installed in the 1888 drift as soon as it arrives.——The Sycamore company, operating on the Verde river about 13 miles from Jerome, has sunk the new two-compartment shaft to 325 ft. A good strike of ore was recently made, picked samples assaying 7% copper, $18 gold, and 6 oz. silver. A proposition is under consideration to install a complete water-power plant, as the Verde river will furnish an enormous amount of power, if properly harnessed.——The Haynes Copper Co., owning the Harry-hansen group of claims, is installing the heaviest plant in the district, exclusive of the United Verde. They are sinking a three-compartment shaft, but at a depth of 130 ft. a heavy flow of water was encountered, compelling them to abandon work until the arrival of pumps. They are at present putting into place three boilers, 50 hp. each, an 8-drill Ingersoll compressor, a double-drum hoist, and a Cameron sinking pump. This property is considered one of the best in the district, and developments are awaited with interest.——The main shaft on the Verde Grande has attained a depth of 530 ft. and sinking is progressing rapidly, under the supervision of Mr. Bevin. Developments have warranted the cutting of a station on the 500-ft. level. Numerous small veins of ore have been found, but no large orebody, although the presence of sulphides throughout the formation leads to the belief that a valuable ore deposit will soon be encountered.——The Little Daisy, owned by the Verde Extension Copper Co., is working right along. The main shaft is down about 700 ft. The flow of water is being handled nicely, but a depth has been attained that necessitates the installation of heavier machinery, and the showing in the mine is such that a large and complete hoisting and pumping plant will soon be placed on the property.

The Boston and Jerome property, adjoining the Verde Grande, is shut down, as the heavy flow of water could not be handled with present equipment. Joe Larsen, the superintendent, states that the proper machinery will be installed during the next 90 days.——The Pittsburg & Jerome property, which is being financed by Pittsburg capitalists, will resume operations about March 1.——The Mescal Copper Co. recently started development work on their property in Mescal gulch, near Mingus mountain.——The Two Republics Mining Co., operating near Mingus mountain, about 10 minutes from Jerome, is at present driving a tunnel, and expects to install machinery soon.——Rothermel & Ross recently acquired the Hogback property, below Jerome, and will begin development work at once.——The main shaft on the Arizona & Arkansas property, locally known as the Royal Irish, is down about 600 ft. A drift is being run from the 600-ft. level for the purpose of cutting a large dike.

Prescott, Feb. 10.

CALIFORNIA.

NEVADA COUNTY.

(Special Correspondence).—Extensive work is under way in the upper levels of the Brunswick mine. Most of the present activity is above the 1250-ft. level. The ore below this point is lower-grade than that found in the upper workings. The management has recommended to the stockholders that a new vertical working shaft be sunk and a large pump installed in the old shaft to handle the

water with one lift. No dividends were paid in 1907, but extensive development was accomplished. C. Mallon is superintendent.——The Greek vein has been struck in the Union Hill mine. Two good bodies of ore are being developed and several men are employed. The Wiltsee vein is showing well.——Sinking continues at the Kenosha and the vein is looking well. Some specimen ore was recently extracted and placed in the vaults of the Nevada County bank. A 3-ft. vein of milling ore is disclosed in the 65-ft. shaft at the Aurora mine. The ore runs about $10 per ton. A small force of men is employed and the shaft is steadily going down. The property was recently inspected by San Francisco shareholders, who were well pleased with the condition of it.——The vein on the 500-ft. level in the Idaho-Maryland continues to show well with increased depth. Considerable ore has been extracted and 10 stamps are dropping steadily. Limited work is going on at other points.——Sinking at the Central Shaft continues. Excellent ore is being developed.——Milling ore is being extracted from the upper levels of the Niagara mine.——A small force of men is developing promising ore in the Bear River mine.——At the Midas the shaft is rapidly nearing the point where it is expected to intersect the main orebody.——A limited amount of work is steadily prosecuted

at the Jenny Lind mine. A small crew of men is employed.——Good progress is being made in driving the cross-cut at the Conlan mine. Small quantities of high-grade ore are being developed in the shaft. It is announced that a large force of men will be employed, and that the company has ample funds to meet the claims against it.——At the Anchu mine a raise is being run to connect the upper and lower adits. The vein in the raise has widened to 6½ ft. The ore is of fair milling grade.——Negotiations are under way for the purchase of the Pittsburg mine by Oakland capitalists. This property has been idle for several years, although considered to possess merit.——A large tonnage of low-grade ore is being developed in the Champion mine. Rich quartz is coming from the Home workings.——It is rumored that the independent copper mine owners of the county are considering the formation of a merger which will facilitate the advantageous working of their properties.

Grass Valley, Feb. 10.

Twenty-five men narrowly escaped being suffocated by a fire in the Brunswick mine. One man, Harrison Eastus, is still in a dangerous condition. A number were hoisted to the surface unconscious from the effects of bad air. The cause of the fire has not been determined, as it is impossible to get to the point where it started. It is believed to be due to motors burning out at the 700-ft. level.——Eastus, the pump-man at that station, was startled by a loud explosion, and the next instant the pump station burst into flame. He attempted to check the fire with a hose, but was unsuccessful, and then started to the surface. He climbed 200 ft. but was there overcome by the smoke, and found later unconscious.——William Bawden made seven trips through the heavy smoke and assisted in bringing out every man. The fire is not expected to do much damage, as the timbering outside the pump station is too wet to burn.

The Murchie mine is now yielding in the lower levels a higher grade of ore than it had ever before produced; 20 stamps are crushing it.——A small vein of high-grade milling ore was exposed in the Belle Union mine by a round of shots fired while the directors were visiting the property.——A public meeting of the property owners and people residing on San Juan ridge has been called for the purpose of learning the sentiment as regards the movement on foot to resume hydraulic mining all along the ridge. It is proposed to conserve the waters and keep the debris on the ridge, so as to comply with the Federal laws. This means that the hearty co-operation of the people is necessary, as great lakes, restraining barriers and ditches would have to be constructed.——At the Aucho mine a raise which is being driven to connect the upper and lower adits has exposed good ore 6½ ft. wide. Several test runs of ore made in the 10-stamp mill gave satisfactory results: Harry Overman is manager.——Local papers announce the discovery in the Kenosha mine near Grass Valley of a rich ore-shoot "which is said to show a width of nearly four inches of solid gold."

PLACER COUNTY.

E. Witherspoon and J. Young are working a prospect on the North Fork of the American river near its junction with Granite creek. The gravel is rich with coarse gold. A number of men are working at the Eureka, above Westville, exploiting the southern vein. The channel has been found, but its extent and character have not been determined. W. C. Rose of Reno has secured an option on the Gold Blossom.——F. Pellon has bonded the California mine. This vein is an extension of the Bellevue and carries rich ore.

PLUMAS COUNTY.

Rich ore has been recently found in the Arcadia mine, at a depth of 500 ft. below the surface. The vein is said to be 3 ft. wide. The mine is on the south side of North Canyon, below the Round Valley reservoir, and is a part of the mineralized district extending through the Green Mountain range and extending westward to the North Fork of Feather river.

SACRAMENTO COUNTY.

A story comes from Sacramento that the Pneumatic Dredge Co., which is preparing the East Side Park tract for a pleasure ground, has discovered a pay-streak of gold-bearing gravel in the course of its excavations. The discovery of gold in some borings led to careful tests; the sand recovered from depths of 28 and 30 ft. gave an average result by assay of $1.02 gold per ton. It is thought possible that a great body of rich gravel underlies the State capital.

SHASTA COUNTY.

The Bully Hill Copper M. & S. Co. have contracted with Holt & Gregg of Kennett for the supply of 100 tons of lime stone a day. It is expected that the railroad to Delamar will be completed by the end of February, and that smelting will be immediately commenced. Three shiploads of coke are now in storage at Pit and other points on the railroad, waiting for transportation facilities to Delamar.——At Heroult, experimental work is being steadily continued on the electric smelting of Iron, with favorable results. Renewed activity in construction work will commence as soon as the weather improves.——The Midas mine at Harrison gulch has been worked continuously during the winter, and the Gladstone mine is a steady producer.

Map of Northern California.

At the Mammoth smelter the large Nordberg compressor has been started up. This machine has a capacity of 1700 cu. ft. per min., and is operated by a 750 hp. motor with a rope drive.

TUOLUMNE COUNTY.

The new 10-stamp mill of the Imperial group of mines at Jacksonville is running steadily. Costs are said to be 75 cents per ton, the ore being quarried. A. S. Kahl is superintendent.

COLORADO.

TELLURIDE COUNTY.

A fatal accident occurred at the Lewis mine in the Bridal Veil basin, caused by a slide, which demolished the shaft-house. Two men were killed.

GILPIN COUNTY.

Sinking is under way at the Slide mine on Pewabic mountain and a depth of over 100 ft. has been gained; Mark Harris is manager.——Lessees at the Two-Forty property in Harris gulch are shipping to the Argo plant ore that carries $18 to $20 per ton.——H. F. Pool & Co., who are working on the 440-ft. west level of the West Notaway mine in the Russell district, are reported to have shipped to the Chamberlain sampling works 5 tons of ore that carried $180 in gold, silver, and copper per ton.——Denver people who have taken a lease and bond on the Onoko and Parole properties in Leavenworth gulch, will

install the plant of machinery now at the Forks mine in the Nevada district.——Thompson & Hambly have the contract for the erection of new orebins at the Anchor mine in Willis gulch.——Driving is proceeding on the 220-ft. level of the Ingeborg mine at Winnebago hill; the lode is 3 to 4 ft. wide. Shipments have yielded 2½ oz. gold per ton. ——G. K. Gimball is having the water taken out of the Waltham mine in Russell gulch to permit an examination of the property.——The Tip Top claim, situated on the summit of Pewabic mountain has been sold to Illinois people; in the 60-ft. shaft there is a 4-ft. streak of mineralized quartz that is said to carry $8 to $11 per ton.

IDAHO.

IDAHO COUNTY.

A body of ore 11 ft. wide has been recently found in the Black Diamond mine in the Dixie district. High-grade ore has been found in a tunnel 180 ft. long in the Coeur d'Alene group of claims on Santa Ann creek.

OREGON.

BAKER COUNTY.

The new quicksilver smelter at Black Butte is being blown in. The smelter has a capacity of 500 tons per 24 hr., and is designed by W. Denis. The furnace has several new features, the wood fire being maintained above the stack, which is about 40 ft. high, and the hot gas drawn down through the charge by draught induced by electric fans. The mine has been developed to a depth of 1700 ft. and large ore reserves are blocked out.——At the Buffalo-Monitor mine, rich ore has recently been struck. The mine is under the management of N. Berkeley, the owner.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—Goldfield is quiet and dull; from appearances one would hardly imagine that troops were at any time necessary.——The new Goldfield Consolidated mill on the other side of Quartz Mtn. will in all probability be a model plant in every respect. The experience gained from the 20-stamp mill of the Combination mine should furnish valuable data for the new one. The present mill shows the effects of putting up a mill for an ore that is so changeable in character that a compromise process had to be adopted to suit the mixed product from the mine; the mill has had so many additions that it appears uncouth. The metallurgist in charge deserves sympathy. Grading on the new millsite and the grading of a road around Quartz Mtn. is the only work that has been commenced. The 20 stamps of the old mill are running but the concentrators have been cut out, probably for a test run. Outside of the work in the Combination and a few leases on the Florence, no mining work is being done about here. There are hopes of others soon starting up, but no positive information. The Florence mill, being put up by Mr. Hennesy, may take about two months more for completion. The process will be sliming of all the product without any amalgamating plates at all. The 20 stamps in units of ten are of 1000-lb. weight, with concrete mortar-blocks (six parts of sand and rock to one of cement) and wooden battery posts. The pulp, after being crushed to 12 mesh, will be screened, the fine going over Wilfley tables, the coarse being re-ground in a 19-ft. tube-mill lined with 5-in. silex blocks, and using flint pebbles. The oversize will then be ground in another tube-mill and concentrated. The cyanide department, arranged conveniently in the same building, will consist of six vats, Butters filters, and several zinc-boxes. The cost of the whole plant will be about $150,000, including about $25,000 for the pipe-line from Montezuma Mtn., and concrete water-tanks holding 250,000 gal.——The Pittsburgh Blair mill at Blair will soon be in operation.

Rawhide is about 25 miles east of the upper end of Walker lake. The population is about 2500 and the influx of people is unparalleled even in the history of mushroom camps. There is little good sleeping accommodation in the camp at present, but plenty of food can be had at reasonable prices. Water costs $2 a barrel and wood is now $35 per cord, but these prices will go down as soon as the effects of the recent storms are over. Pinon wood is obtained from the mountains about 25 miles to the south, and water from good wells 6 or 7 miles distant. Present indications suggest that the most valuable deposits of ore will be of good milling grade, and hence it is expected that the camp will have a great future.

The discovery is about a year old, but it is only during the last four months that there has been much activity. On the Kern lease, a shaft has been sunk 110 ft., in ore all the way, and now a 25-hp. gasoline hoist, the first application of power in the camp, is being erected. There are about 30 leases at work.——Good ore has been found in two shafts on the Grutt property.

ELKO COUNTY.

On Lime mountain a group of claims owned by Jacob Eggers is said to have a series of veins of high-grade copper-lead-silver ore; recently a cut 20 ft. long, 14 ft. wide, and 12 ft. deep has been dug entirely in copper ore.——At Ruby mountain, 55 miles south of Wells, the National Development Co. is driving two adits on a vein of high-grade lead ore; teams are hauling the ore to Wells for shipment to a smelter when the market improves.

Map of Southwestern Nevada, Showing Position of Rawhide.

HUMBOLDT COUNTY.

The Seven Troughs Leasing & Development Co., which is operating a lease on the Delaware property near Vernon, intends to install a modern hoisting plant and other necessities for rapid development work. The shaft is 200 ft. deep; numerous drifts and cross-cuts have been driven but as yet only ore of milling grade has been found.——A specimen of Mazuma Hills ore displayed in Lovelock weighed 70 lb. and was estimated to contain $30 to $40 per lb.——The Mother Lode Mining & Leasing Co. has increased its force at the Gold Run mine near Vernon.——Wheeler & Harris have found a promising vein on their property at the head of Stone Horse canyon.——It is expected that the new 10-stamp mill of the Seven Troughs Kindergarten Mining Co. in Seven Troughs canyon will be in operation on April 1.——At the Bard lease on the Seven Troughs Therein mine, there has been found a vein that carries $5 per ton.

——A 15-hp. gasoline hoisting plant is to be installed at the Gold Run No. 2 claim; the shaft is 85 ft. deep.——A strike of fairly good ore on the Yellow Dog claim of the Seven Troughs Fine Gold Mining Co. has caused several lessees to resume work.——An adit is being driven at the Seven Troughs Tomboy property.——On Feb. 6 a big rush to a new gold discovery 10 miles west from Brown station started in Reno. The cause was the discovery on Feb. 2 of some very rich specimens of gold quartz that are described as being "of that gold-spangled, gold-studded variety which is comprehensively denominated picture rock." John and Joseph Macidon of Lovelock made the discovery and they have staked all the claims they want.

LANDER COUNTY.

(Special Correspondence).—The Hider-Nevada Co., with John J. Broecher as manager, is developing a group of claims in Wild Horse range, situated 24 miles south of Battle Mountain and 9 miles west of the Nevada Central railroad, which extends to Austin. This mountain range is made up of beds of dolomite having a north-south strike and a dip to the west. The ore occurs in garnet zones, of which there are four, running parallel. Within these are lenses of ore in a garnet and silicious gangue, the copper being oxidized. A 120-ft. shaft cuts mainly through a gossan, but at the bottom of the shaft a body of ore was entered that is 2 ft. wide, running over 16% copper. On the same belt a 70-ft. shaft has been sunk, and in it was encountered a vein 15 ft. wide, the ore in which runs 2% copper. A portion of it is said to run 5% copper. In the bottom of this shaft a sulphide ore was found that carries 9 oz. silver and $1.60 gold per ton. The intention is to sink a 500-ft. shaft and from it run cross-cuts through the formation at various levels. A diorite dike that is said to be mineralized crosses the mineral belt herein described.

Battle Mountain, Feb. 14.

LYON COUNTY.

At the Homestake mill, the retaining walls and battery foundations are finished, and it is expected that the construction work will be finished during May.——It is stated that the Ramsey-Comstock mine at Ramsey has been examined by engineers representing Samuel Newhouse. A few shipments have been made, but the mine has been systematically developed and a considerable tonnage of ore is now ready for extraction. The Ramsey-Comstock was discovered by Charles Clark in April, 1906, and sold to A. H. Mayne and his associates, who developed it on four levels by several drifts.

The Western Gypsum Co. has arranged to ship two carloads of gypsum per day from Mound House to the plant between Reno and Sparks and to the old plant in San Francisco.——The Nevada-Douglas company has a smelter site of about 85 acres of ground on the dry lake-bed in Smith valley where it will be isolated from the rich agricultural section of the Yerington district.

NYE COUNTY.

Good progress has been made on the M. & M. lease on the Great Western mine. The shaft is sunk to 140 ft. and cross-cutting to the south has been begun. The gold has been found associated with a talcy material stained with hematite.——The Great Western Mining Co. has passed into the control of the Round Mountain Mining Co. This company's mill has been averaging 72 tons of ore per day. The January clean-up amounted to nearly $30,000.

Tonopah shipments last week amounted to 5608 tons. At the Midway sinking continues on the winze from the 835 level, which is down 120 ft.——From the Belmont 950 tons were extracted last week, principally in the course of development.——On the North Star, drifting is being continued on the ledge which was struck on the fault-plant at the 1250-ft. level, about 560 ft. north of the shaft.——The Tonopah Mining Co. continues to drift westerly on the Valley View ledge on the 240, 340, and 440 levels. Good ore is being encountered in each drift.——Cross-cuts have been run north about 600 ft. west of the shaft, on the 340 and 440 levels of the Silver Top claim, and as a result a body of good milling ore has been found.——On the Mispah, ore is being extracted from all the levels down to the 600 level, where good ore is being stored in the Mispah vein, west of the shaft.——In the Montana-Tonopah, a body of ore over 8 ft. wide has been encountered at a depth of 462 ft., about 200 ft. east of the shaft. Drifting is progressing on the Martha ledge on the 600-ft. level, about 950 ft. west of the shaft, following the new discovery and going northeast on the vein.——Drifting is being continued on the Macdonald vein to the west, about 600 ft. from the shaft, disclosing a good vein 6 ft. in width.

STOREY COUNTY.

Last week Ophir produced 332 tons of ore, valued at over $18,000. Favorable reports also come from Andes and Yellow Jacket. In the former, ore has been found at a depth of 250 ft. and the latter is producing 150 tons of ore per day.

WHITE PINE COUNTY.

The Nevada British Mining Co. has erected a 40-ft. gallows frame, installed a gasoline hoist, and has a force of men sinking the shaft at the Chief of the Hills mine near Cherry Creek; a compressor plant will be put in soon and the shaft will be sunk to a depth of 800 ft.——The Nevada Mother Lode Mining Co. has let to Ryan Bros. & Taylor a contract to drive an adit 800 ft. long at its mine in Silver canyon. Two Sinclair air-hammer drills have been installed; J. W. Walker is manager.

UTAH.

BEAVER COUNTY.

The Star district is now attracting considerable attention. The Hub property, owned by the Utah Mining & Transportation Co., has been opened to a depth of 200 ft. and down to this depth the workings have been in splendid ore. One shoot, 5 ft. wide, is rich in silver, lead, and copper.——Another body of ore, rich in lead and silver, has recently been opened by the Buckeye Cons. Mining Co.

CANADA.

BRITISH COLUMBIA.

A. J. McMillan, managing director of the Le Roi, and W. A. Carlyle, consulting engineer for the same company, are at Rossland examining the affairs of the company. The latter left Rossland about seven years ago to take charge of the Rio Tinto mines in Spain. He was previously in charge of the Le Roi, Columbia-Kootenay, and Nickel Plate mines. The following tonnage of ore was shipped from the Rossland mines during the week ending Feb. 8: Centre Star, 2840 tons; Le Roi, 1925 tons; Le Roi No. 2, 743 tons; Evening Star, 30 tons. A petition has been presented to the Dominion Government by the owners and managers of the silver-lead mines, asking for an extension of the lead bounty. Only a fraction of the original appropriation has been expended, and it is thought probable that an extension will be granted. The Nelson Board of Trade has sent J. L. Retallack to Ottawa to work for a continuance of the lead bounty, which bounty expires next June.——At a meeting of the directors of the Sullivan Group Mining Co. it was announced that the Sullivan ore is self-fluxing and that in the future no ore will be shipped from outside points for fluxing purposes.——A carload of rich galena ore has been shipped to the Trail smelter from the Lightning Peak mine on the west shore of Arrow lake; all the ore had to be rawhided down the mountain for many miles.

NOVA SCOTIA.

At the Micmac mine, in the Bridgewater district, a hydro-electric plant is being installed, and the production will be increased to 100 tons per day. The ore developed carries from $10 to $11 per ton and has an average width of 2 ft.

The generating station will be 9 miles from the mine, and the power should cost about $7 per hp. year. At the present time the output is 30 tons per day, with steam power costing $100 per hp. year, and the profit is $5 per ton. It is expected that the increased output and electric power should increase this to $7 or $8 per ton.

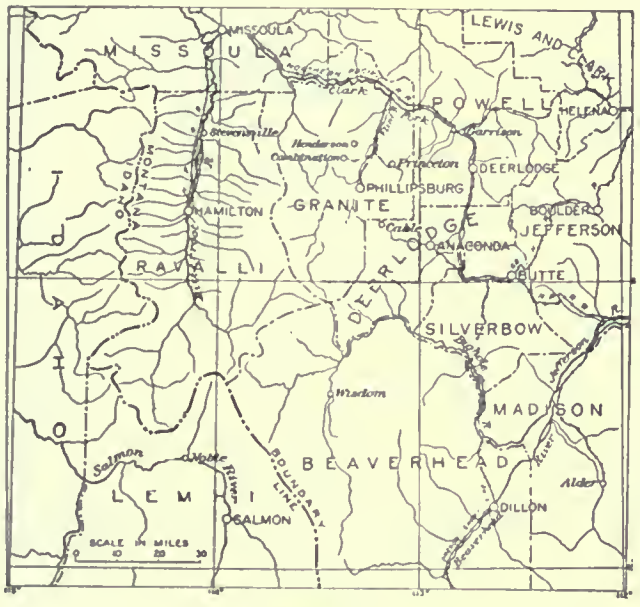
Special Correspondence.

BUTTE, MONTANA.

Amalgamated Mines.—Boston & Montana Operations.—Fighting Fire Underground.—Developments in the Greenleaf.—Davis-Daly Mines.

There have been numerous rumors circulated that the mines of the Amalgamated Copper Co. would resume operations by May 1, but if the Eastern officials have arrived at any such conclusion it is news to the officers of the company here. Still, they say, they would not be surprised if work were resumed in May, that being a long way off. Their surprise would be rather if the mines remained closed that long.

The changes and improvements being made at the Boston & Montana concentrator at Great Falls will be completed by March 1, and the shipment of ore from the mines at Butte will be increased by about 400 tons per day. The present shipments average



Montana.

about 3300 tons per day, and a portion of that is stored at Great Falls, the smelter and concentrator handling only about 3000 tons. The Boston & Montana Co. is maintaining 4000 men at its mines in Butte by working half at a time for a period of two weeks. Ore is coming from the Mountain View, West Colusa, Leonard, Pennsylvania, and East Colusa. Fight against gas and fire in the Leonard and West Colusa is going on. The Mitchell shaft, which was sunk in the neck of the Minnie Healey ground, owned by the Butte Coalition Co., has broken into the fire zone, and the Boston & Montana officers have now become convinced that the seat of the fire is in the Butte Coalition ground, where they at first suspected that it originated. Pipes have been put through the bottom of the shaft into the fire and streams of water have been turned on. Two other shafts, on the Gambetta, are being sunk near the Mitchell; one of them has reached a depth of 670 ft. and the other 500 ft. The Mitchell shaft had reached a depth of 870 ft. when it struck fire. It is claimed that within a month the Boston & Montana will be working in all parts of the Leonard and West Colusa again, as the fire has been thoroughly hemmed and walled in, and when the two Gambetta shafts get a little deeper it is expected that they will be able to take care of all the gas arising from the fire. A new electric pump is being installed on the 1200 of the Leonard to assist in taking care of the water that is sent into the mine. The water pumped out is rich with copper solution.

Cross-cutting has been resumed in the Greenleaf, where the Boston & Montana Co. is doing development work. A heavy flow of water was opened in a cross-cut that was started north from the shaft on the 1000-ft. level, and all work had to be stopped until a pump was installed. There are two other pumps in the Greenleaf shaft, with a combined capacity of 600 gal. per min. The north cross-cut is only a prospect, though it is known that there are several veins in that direction. The southern cross-cut is in the direction of the veins that were cut by the shaft, and the first one will be reached within 200 ft. The only work that is being done at any other mines of the Amalgamated Co. is in re-timbering a portion of the Parrot shaft and keeping the shafts at the other mines in repair.

The Davis-Daly Co. is working in two cross-cuts and a drift in the Colorado, about 30 ft. being made in all of them per day. The drift is being run eastward with the object of intercepting the vein recently opened by lessees in the Lizzie claim, another Davis-Daly property. The Lizzie vein strikes northwest, and has been developed to a depth of 200 ft. by the lessees. No other work is at present being done by the Davis-Daly. It was expected that exploration would be resumed in the long cross-cut that was driven from the 1800 level of the Original mine, through an arrangement with Senator Clark, but financial conditions have delayed a resumption of that work, and it is a question of money when work will be resumed there. The company's management is confident that a big mine will be developed through the Colorado. The Lizzie vein will be reached within a distance of 600 ft. from the Colorado shaft.

TORONTO, CANADA.

Settlers' Rights to Mineral Land.—Coal Development.—Shipments From Cobalt.—The Lemieux Act.

The minister of Lands and Mines has introduced a bill in the Ontario legislature amending the Public Lands Act. It provides that when lands not valuable for mines are thrown open for settlement the settlers shall be entitled to all minerals found therein. The measure has also a retroactive effect, and rescinds all reservations of minerals in patents heretofore issued, in cases where the title to mineral rights remains in the Crown and has not been granted to anyone under the Mines Act. The reservation of mines and minerals in lands taken up by settlers has been the cause of much trouble between settlers and prospectors, and the owners of surface rights have been often subjected to disturbance by those subsequently acquiring mining rights on the property.——The Canadian Pacific Railway is undertaking the development of its coal areas at Hosmer, in the Crows Nest region, on an extensive scale. A subsidiary company has been formed, the directors of which are leading Canadian Pacific officials. W. H. Aldridge, consulting mining engineer of the company, is superintending the building of the town, the sinking of shafts, and the installation of modern machinery. The company will spend between one and two million dollars on development work. Eight seams will be opened, the product of all being brought up by one adit. Provision is being made for an output of 3000 tons per day, and it is hoped to begin raising coal by 1909. Most of the coal will be used as fuel for the company's locomotives.

Shipments of Cobalt ore for the week ending February 1 amounted to 371 tons, from the following

mines: Buffalo, 55 tons; Cobalt Lake, 25; Foster, 34; La Rose, 20; Nipissing, 29; O'Brien, 143; Silver Leaf, 32; Temiskaming & Hudson Bay, 33 tons.—— Shipments for the week ending February 8 were 269 tons, contributed by the following: Drummond, 26; King Edward, 31; La Rose, 21 tons; Nipissing, 32; O'Brien, 95 tons; Temiskaming & Hudson Bay, 33; Watts, 30 tons.——The Divisional Court at Toronto gave a decision on February 12 in the appeal case of James McGuire, an official of the Western Federation of Miners, who was convicted by the Police Magistrate of Cobalt of unlawfully inciting the employees of the Nipissing Mining Co. to strike, and fined $500 or six months imprisonment. The Court found the conviction defective and ordered the papers to be amended and the term of imprisonment reduced to three months. The presiding judge strongly criticized the Lemieux Act, under which the proceedings were taken, as being full of defects.

DENVER, COLORADO.

Portland Litigation.—Open Shop.—Bob Womack.—Upper Clear Creek.—Dry Concentrators.—Activity at Cripple Creek.

The now famous Doyle-Burns case is to be reopened again. This case involves the transfer of about $1,000,000 worth of stock in the Portland Gold Mining Co. It has dragged along through the courts for more than six years, and is now no nearer settlement than at first. Neither party will accept a decision when it is against him. The latest move is the filing of a motion in the District Court at Council Bluffs, Ia., for a change of venue from Pottawattomie county to some other county of the fifteenth judicial district. There are so many laws in the statute books now that it seems needless to enact more, but certainly there should be fixed by law a reasonable length of time at the end of which a case between parties or individuals must be finally settled.

Notices have been posted in the Rio Grande railroad shops at Denver and Grand Junction that after March 13 all agreements with the men as to wages, hours of labor, and other conditions will be abrogated. This is evidently an endeavor on the part of the railroad to adopt the 'open shop' policy.—— The *Colorado Springs Gazette* has started a fund for the relief of Bob Womack, the discoverer of Cripple Creek. The usual fate of a prospector was his. Others have been enriched by the great camp he brought to the world's notice, and now it is pleasing to see the generous contributions to the fund for his relief. Womack is a helpless paralytic and absolutely dependent upon his sister for support. The various newspapers of Cripple Creek and Victor have also joined in the work.

Upper Clear Creek district is more active than is usual at this time of year. The shipments for January showed an increase of nearly 25% over the production of the same month for the past two years. The owners of mines producing lead ore are rejoicing over the new schedule announced by the Chamberlain-Dillingham sampler at Georgetown. While this schedule is favorable on lead ores it is still too low on zinc ores to be of any assitance to those mines that have had to close on account of the price of zinc. Lessees in the Mendota mine at Silver Plume have developed a small body of ore and there are several applications for leases on the Seven-Thirty and Burleigh Tunnel properties.——A great deal of ingenuity is being displayed by inventors who are trying to develop dry concentrators and amalgamators for working dry placers. There are two of these machines on exhibition now in Colorado Springs. The concentrator is the invention of McKesson and Black, who have a satisfactory dry concentrator with a wide range in treating unclassified material. The amalgamator has been patented by Louis Chandler. It is designed to pass the sand over eight troughs filled with quicksilver and agitated by a spiral screw. It is evident from the results already obtained in the treatment of ores where water is scarce that dry concentrating will soon be an important branch of ore-dressing.

Confidence in Cripple Creek is more in evidence as the month progresses. The secretaries and general managers of several of the mining companies report numerous applications for leases, and almost daily some new agreement is filed for record.

SALT LAKE, UTAH.

Utah Con. Smelter.—The Yampa Mine.—Utah Copper Concentrator.—A Large Plant.—Interesting Details.

The Utah Consolidated Mining Co., owner of the Highland Boy mine at Bingham, has made a year's contract with the American Smelting & Refining Co. to ship 800 tons of ore per day to the latter's Garfield smelter, with the privilege of renewal at the end of the first year. This contract was the result of the injunction order forbidding operation of the Highland Boy copper smelter, as asked for by the farmers of the valley. The intention of the Utah Consolidated Co. is to erect a new plant at a site where its smoke and fumes will not menace the farmers. It is understood that plans and drawings for the proposed new plant are complete. The site has not been announced.

It has been decided by the Tintic Smelting Co. to install a copper furnace, 48 by 108 in., in addition to the lead furnaces now in course of installation.

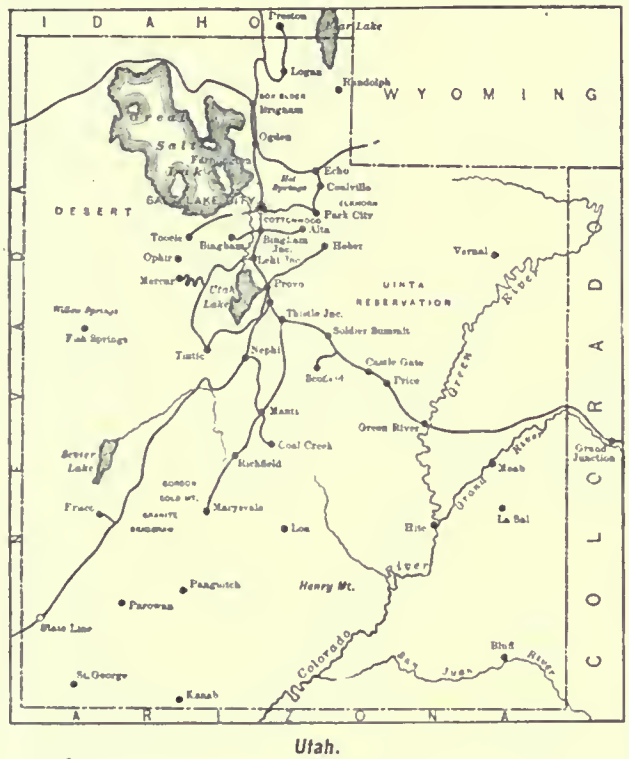
The Yampa mine at Bingham was recently equipped with a new Ingersoll-Rand air-compressor, which will result in increasing the drill force. At present 30 drills are in use. The Yampa is opened by a 3000-ft. haulage adit, in which electric power is used. This main adit first strikes the vein obliquely and then follows along its strike. It is connected with an incline that goes to the surface at about a 30° angle, on the dip of the vein. This adit is considered the 1200-ft. level of the mine, most of the present mining being done above it. The orebody, as shown by the workings, ranges in width from 8 to 16 ft. J. C. Dick is general superintendent.

The Jennie Gold Mining Co., whose property is at Gold Springs, 14 miles from Modena, is operating a mill that is equipped with 12 Nissen stamps, with an amalgamating plate in two sections below each stamp, followed by a Pierce amalgamator. In this way the mill is treating 75 tons per day. Equipment is being put in for separating the sand and slime; also agitating tanks, leaching vats, and a Kelly filter press. The ore, carrying gold and silver, runs $10 to $12 per ton. C. A. Short, who has been connected with the property for several years, is manager. The mill was designed by the General Engineering Co. of Salt Lake.

The Utah Copper Co. is treating 800 tons of ore per day at its Copperton concentrator and 4000 tons per day at its new Garfield plant. As soon as all sections of the latter are set in operation the plant will be handling 6000 tons of ore per day, this being the capacity for which it was designed. The Garfield plant is composed of twelve 500-ton units, eight of which are in operation. The ninth unit is expected to be in operation by February 15, and the three additional units will doubtless be ready within 60 days. Each 500-ton unit is a mill complete within itself and may be operated independently of the others. Thus an accident or any breakage requiring

repairs in the machinery of one unit does not affect operations of the other units. The dimensions of the plant proper are 600 by 508 ft. The ore-bin, adjacent to the main building, is 600 ft. long, 40 ft. wide, and 24 ft. high. The area covered by the main building and ore-bin is equal to seven acres, while the floor space in the main building aggregates over eight acres.

The three principal features of the milling process employed consist of coarse crushing, fine crushing, and concentrating. In the coarse crushing department there are four No. 7½ gyratory crushers, each having a capacity of 100 tons of ore per hour; and four 54 by 20 in. roughing rolls. The crushers and roughing rolls reduce the ore dry to ¾-in. size. After leaving the coarse crushing department, the ore is subjected to wet processes. The fine crushing department contains 36 six-foot Chilean mills and 24 sets of 16 by 36 in. rolls. The method and arrange-



Utah.

ment of the crushing departments necessitate the use of a number of elevators to take the crushed material to the trommels for sizing. The fine-crushing machinery reduces the ore to 40-mesh before passing it to the concentrating department. The equipment for concentrating consists of 72 single two-compartment Hartz jigs, which serve as separators and sizers, for no jig product is made; 48 Wilfley tables, which stand at the head of this department, handling the coarser material; 1104 six-foot vanners of the suspended type and a modification of the Johnston vanner; 24 four-compartment classifiers, and 384 nine-foot conical settling tanks. All this machinery is set on re-enforced concrete floors, supported by steel columns. Those vanners handling the coarser material have corrugated surfaces, while those treating the slime have smooth surfaces. The concentrate from all the tables passes automatically into concrete settling tanks, where the water is drained off through filters, after which the concentrate is loaded into railroad cars by an electrically operated crane with clam-shell bucket.

The mill is provided with a system for heating the air by steam coals, taking the exhaust from the engines that drive hot-air fans. The water supply for mill work and fire protection is supplied from two reservoirs above the mill—one for high pressure and the other for moderate pressure. These are kept filled by a pumping plant that throws 10,000 gal. per minute.

All mill machinery, pumps, and shop machinery are operated by electric power, generated by the Utah Copper Co.'s own plant, in close proximity to the mill, which is one of the largest and most modern that exists west of the Mississippi. Its equipment comprises 20 water-tube boilers, of approximately 12,000 hp., which drive five cross-compound condensing engines, each direct connected to an alternating current generator. Two of these generators are 1500 kw. each and the others are 2250 kw. each.

According to the annual report by D. C. Jackling, the general manager, the Utah Copper Co. is now producing copper at the rate of 3,000,000 lb. per month, at a cost of less than 8½c. per lb., and he predicts that the company will be producing copper at a cost of 7¾c. per lb. within the next 12 months.

MEXICO.

Santa Eulalia.—Purchases by Schwab.—The San Toy.—Railroad From Gutierrez.—National Finances.—Splendid Surplus.—Exports and Imports.—Production of Metals.

The failure last fall of F. August Heinze prevented the completion of the deal for the purchase of the holdings of the Potosi Mining Co. and the Chihuahua Mining Co. (controlled by Grant B. Schley and associates of New York and Dennis Sullivan of Denver) in the Santa Eulalia district of Chihuahua. Examinations were made at the time, as mentioned in these columns. After the failure of Mr. Heinze the option, if such there were, passed to others (presumably to Chas. M. Schwab and friends), for whom a thorough examination of the Potosi and Chihuahua properties has just been completed. Coincident with the completion of this examination, Donald B. Gillies and Malcolm MacDonald, both Schwab men, left Chihuahua for the United States, either Pittsburg or New York. It would seem therefore that there is no question that the Schwab interests are behind the deal. And as Mr. Gillies is president now of the San Toy Mining Co., of Santa Eulalia, and this company and Mr. Schwab have both made public denial of having or ever having had any connection with the Dolores suit, in which J. P. Hutchinson, former manager of the San Toy, is interested, and as in that denial Mr. Schwab took occasion to state that Donald B. Gillies was his representative in Chihuahua, and further, as it has been known that Mr. Schwab is largely interested in the San Toy Mining Co., it is not far fetched to draw the conclusion that a consummation of the deal for the Potosi-Chihuahua means an immense consolidation of all the holdings of the Chihuahua Mining Co., the Potosi Mining Co., and the San Toy Mining Co., than which only the Greene-Cananea combination can be looked upon as larger in the whole of Mexico. The Potosi mine has been said by many who have had the privilege of visiting it to have opened up the largest bodies of silver-lead carbonates and argentiferous iron ore on this continent, and it is an immensely rich zinc carbonate property as well. The Chihuahua has been shipping in the neighborhood of 300 tons per day for many years and seems only to be limited by the transportation facilities available. The San Toy has only in the last year become a large shipper, but large bodies of low-grade ore are opened up and the production can easily be increased to 300 or 400 tons per day. Those who have kept in close touch with operations in Santa Eulalia state that the only question as to the completion of this deal is the ability of the Schwab coterie to raise at the present time the money required for the transaction, for the size of

the properties and the standing of the sellers (practically the Standard Oil) means that it will be no small sum. The San Toy Mining Co. has completed its new extension of one mile of tram, which will give service from the terminus of the aerial tram, completed last spring, at the Galena shaft. This tram is 4½ miles long and reaches to the Bustillos, Central, and Juarez mines, which three were bought last year from Manuel Gameros by Donald B. Gillies for the San Toy. The new extension of the tram also passes the San Juan and El Cristo, on which J. P. Hutchinson, former manager of the San Toy, has obtained a short option.

Whoever has been called upon to make that stage ride from the station of Gutierriz on the Mexican Central to Sombrerete, in the State of Zacatecas, leaving Gutierrez at midnight and arriving at Sombrerete at noon, than which for the same length of time there is none worse in Mexico, will be pleased to learn that the first 40 kilometres of the railroad to be built between the two points has been permanently designated by the Mexican Western Construction Co., under the direction of V. P. Safford, and grading will be started as soon as the line has been approved by the Government. The total length of the road when completed to Sombrerete will be 135 km., and if extended on to Chilchihuites it will be about another 40 km., while if continued on through to Durango, as it should be in order to take in other mineral districts, as Vacas and La Parilla, and the agricultural lands around Nombre de Dios, as well as to give a decided short cut between Durango and Mexico City, it would have a total length of something like 300 km. or 185 miles. This is a road that should have been built many years ago, and had it been done R. S. Towne, who is behind the present move, would have saved almost enough to have paid for its construction from the costs of his wagon freightings to and from his Sombrerete mine, of the Sombrerete Mining Co., or the Mexican Metallurgical Co., of which he is president.

Of great importance to all who are interested in Mexico must be the report to the Mexican Congress of the Minister of Finance, Julio Ives Limantour, for the last fiscal year, ending June 30, 1907. The most important item in this report is the splendid surplus, amounting to 29,209,482 pesos, the largest in the history of the Republic, and considerably in excess of the entire revenue for 1886, which amounted to 26,980,895 pesos, a most remarkable showing in 21 short years. But a little over a dozen years ago such a thing as a surplus in the country's finances was looked upon as an impossibility. It was under such conditions that Mr. Limantour took up the ministry of finance; many reforms were at once instituted, the country began to be credited abroad, and at the end of three years the results became manifest, the unexpected occurred, and the fiscal year 1896 closed with the first surplus ever known, amounting to 5,451,347 pesos. From that time the revenues have increased steadily, but the surplus, though maintained, has varied greatly until in 1903, with a revenue of 76 million pesos, the surplus amounted to 7 millions, then 10, then 12, then 22, and last year over 29 millions of pesos, as stated above, the total revenues for 1907 amounting to 114,286,112 pesos and the expenditures to 85,076,640, this latter being an increase of 7% over the expenditures of the preceding year. The sum total of all surplus amounts since 1896 foots up to something over 111,500,000 pesos, but in addition to ordinary expenditures over 35,000,000 pesos has been expended in public improvements, such as port works, waterworks, warships, buildings, sanitation, city utilities, and improvements, so that the cash reserve on June 30, 1907, amounted to 75,646,700 pesos. The public debt on that date was 444,530,711 pesos. During this fiscal year Mexico's imports amounted to 233,000,000 pesos and her exports to 248,000,000, a balance of trade in her favor of 15,000,000 pesos. Of the exports 176,000,000 pesos and of the imports 146,000,000 pesos were in trade with the United States. What the mining interests of the country amount to is readily shown in a slight classification of the exports as follows: Mineral products, 160,246,003 pesos; vegetable, 71,810,374; animal, 11,151,928; manufactured and sundry products, 4,809,602; showing thereby that over 64% of the total exports were mineral products. Of these 160,000,000 pesos of exports from the mines, gold was exported to the amount of 23,873,713 (the total production of gold being 36,563,898 pesos and the surplus of production over export being coined by the Government for circulation in Mexico); silver was exported to the amount of 99,861,790 (the total production of silver being but 77,088,827, so that the increase of export over production was made up of silver coins in actual circulation in Mexico, an amount almost exactly equal, as may be seen above, to the gold coined and added to the circulation); and the copper exported amounted to 28,792,779 (5,000,000 in excess of the gold exported), leaving 8,000,000 pesos as the value of the lead, zinc, antimony, and other metals exported. Mr. Limantour's report goes on to show that only seven of the products exported were in excess of 5,000,000 pesos (silver, copper, and gold as shown; henequin amounting to 31,440,246 pesos; hides and skins, 8,909,974; coffee, 7,237,529; and rubber, chiefly guayule, 6,678,926), and he calls attention to a much needed diversity in the country's enterprises, for, as they are now limited, the country as a whole is too liable to disaster from a fall in prices or demand of a few articles, as is now the case by reason of the fall in prices of silver, lead, and copper.

The chartered banks of the country show a capital subscribed of 162,600,000, an increase of 16,000,000 over the previous year; assets and liabilities, 723,763,584.96, an increase of 94,881,750.12 over the preceding year; the accounts current were 260,080,521.24 pesos, and the total cash 75,247,200.05. The total railroad earnings on freights were 53,529,981 pesos (an increase of 9.3%) in the handling of 9,538,354 metric tons(an increase of 6.4%); and on passengers, 15,942,776 pesos (an increase of 30.7%) in the handling of 10,187,121 people (an increase of 16.7 per cent). Certainly the best fiscal year for the Republic of Mexico.

The locator of mining claims in Mexico will learn with pleasure that the land office has issued instructions to the various agencies for engineers and surveyors to the effect that in future they will be required to give more data in the description of the location of claims and more exact maps. It is an exaggeration to say that there is not a mining camp in Mexico free from a woeful mass of errors, due partly to the ignorance but chiefly to the carelessness of the Mexican engineer. Many are the tracts of ground, fractions, etc., that are not covered by denouncements and belonging to no one because of misplaced corners, but they cannot be denounced because the plans show the ground as covered and the acceptance of a location thereon by the Government would be an admission of the inaccuracy of the plans. Nor can they be worked, because an adjoining claimant may lay claim thereto, and so it remains truly 'no man's land' unless some wily neighbor quietly moves his corners so as to take in that which is not supposed to exist and has no existence on the records. It is hoped, therefore, that the new orders may compel an accuracy and care in the future that has been long wanting in the past.

LONDON.

British South Africa.—Conditions in Rhodesia.—Consolidation of El Oro Companies.—A South American Venture.—Copper in the Transvaal.

The shareholders of the British South Africa Co. met together this week in great force to listen to speeches delivered by Henry Birchenough, the Marquis of Winchester, and B. F. Hawksley, the subject being the present state of development in Rhodesia. Your readers are probably aware that Rhodesia is not progressing so rapidly as its founders hoped, or as the shareholders desire. For many years we have been accustomed to financial statements saying that as yet the expenses have been greater than the income, but that the succeeding year promises an equalization of these items. Not only have the shareholders been disappointed, but during the last year or two there have been serious signs of discontent in the country itself; so much so that the directors were forced to send a special deputation for the purpose of arguing the case with the population of the country and of ascertaining if anything could be done to remove the manifold grievances. This deputation spent several months in Rhodesia and reported to the directors, who took steps immediately to remedy some of the defects of organization. The news in connection with these innovations and concessions has been published some weeks ago, so that the shareholders were pretty well posted. The shares in the chartered company are as dull as ever, remaining at about 15 shillings. Some years ago, in the boom times, these pound shares stood at £8, and on several occasions the new issues of shares were made at high premiums. It is not necessary to go into details about the new regulations. The new rules about royalties due to the Government from the gold mines are head-aching in their complexity. Nobody but a skilled accountant could follow them. What keeps Rhodesian development back is the absence of bonanzas and the plentiful supply of rules and regulations. There were bonanzas in the West of America to attract a population and open up the country, whereas in Rhodesia there is nothing but low-grade or refractory ores, the bonanzas having been worked out by Solomon or the Queen of Sheba. In the West of America there were no rules and regulations; communities, laws, and governments were not formed in advance of industry. There is another reason why the population does not increase rapidly in Rhodesia, namely, the opposition of the present settlers to the dumping of criminals and ne'er-do-weels in their midst. I am compelled by stern logic once more to make a comparison with Western America, but I shall only go so far as delicately to hint that the characters of the early pioneers west of the Mississippi were not all above reproach.

There appears to be some prospect of the once-famous Emma mine being sold. This mine is situated in Utah, and was floated in London by the late Baron Albert Grant for a large sum of money, more than 20 years ago. For a year or two the profits were large, but its end as a large producer came very soon. For years, practically nothing has been done with it, but negotiations have been concluded with William Groesbeck and L. R. Martineau of Salt Lake City for the sale of the mine for a sum of $20,000. Part of this sum has already been paid and if it had not been for the financial stringency in the United States, the deal would have been completed before now. It is such a long time since the Emma figured in London finance that its present passing raises not even a sentimental interest.

The shareholders of the El Oro and the Somera companies will meet together in a few days for the purpose of considering an amalgamation. A few months ago it was announced that some scheme would have to be devised so as to adjust the ownership of the veins cut on the 1000-ft. level. One or two propositions have been discussed, and finally it has been decided by the directors to propose an amalgamation. Each shareholder in the Somera Co. is to receive five fully paid shares in the El Oro in exchange for sixteen £1 shares of the Somera. The shares in the latter company are not fully paid, only five shillings per share having been called. It will be remembered that the Somera was floated two years ago by the Exploration Co. as a subsidiary of the El Oro. The natural way of developing the Somera under usual circumstances would have been to make it part of the El Oro property, but the time was not opportune for spending any further profits of the El Oro in capital expenditure for this purpose, because a good deal had already been spent in developing the El Oro itself and providing increased plant; hence the flotation as a separate company. The management and directorate have been identical and the expenses of administration have not been more than if the two mines belonged to one company. The list of shareholders in the two companies contain a good many of the same names. P. L. Foster and R. M. Raymond are in London at present to explain how matters stand, and there will be no difficulty in getting the consent of the shareholders to the amalgamation.

Mexico.

The difficulties of mining companies in want of capital are well exemplified by the case of the Mining Exploration Co., which owns the Choicas and other properties in the Argentine, close to the Chile border. The company was formed seven years ago, but it was not until the early part of 1905 that any active steps were taken to develop the property. The capital was then increased from £100,000 to £175,000 in order to provide working capital. As time went on, additional money was put up, and the issued capital at the present time is £205,000 in shares and £10,000 in debentures. This money has now been spent, and the company owes considerable sums for work done. It has been necessary still further to increase the capital. Owing to the scarcity of money, various schemes proposed by the directors have fallen through. Finally it has been decided, and approved by the shareholders, to issue 205,000 new shares of 5 shillings each and offer them to the shareholders pro-rata to their holdings. This practically

means a voluntary assessment. Evidently there are a number of shareholders who strenuously objected to a forced assessment, so that the proceeds of the present issue will not amount to the full £40,000, unless some of the willing shareholders take up more than their proportional amounts. This mine is an interesting one, for the ore is plentiful and rich, and the reserves are being rapidly increased. A traction engine road is completed, the mineral railway is nearly finished, and the smelter is being erected. I may add that the consulting engineer and technical director is Robert Gilman Brown.

Another copper company that requires more capital to complete its outfit and development is the Messina Transvaal Development Co. This company was formed exactly three years ago by Chaplin, Milne Grenfell & Co. to acquire property at Zoutpansberg in the northern Transvaal. The copper veins have developed in a most satisfactory manner, in many places the vein being solid chalcocite. The lodes have been proved to the 300-ft. level, and they vary from a foot to five feet wide. So far, the character of the ore has not altered in depth. Some idea of the nature of the mine can be gained from the fact that during the year ended June 30 last, 2967 tons of ore were mined, out of which 768 tons were hand-picked, averaging over 60% copper. This was shipped to England and realized £34,626. The remaining 2199 tons averaged 11% copper, and are being stored for treatment in the concentration plant now being erected. Since June 30 the monthly output has continued at about 350 tons, and about 200 tons of ore averaging 60% copper have been shipped every month. J. M. Calderwood, the consulting engineer, estimates that on December 31 the ore ready for stoping was 15,423 tons, of similar character to that already mined. In order to complete the plant, and to develop the mine generally, some further working capital is required. A number of shareholders have agreed to the issue of new debentures.

JOHANNESBURG, TRANSVAAL.

Cost of Mining.—Drills for Stoping.—The Gordon Drill.——Record Output.—Labor Problem.

The mining community is congratulating itself over the fact that the average working costs of the Rand have been brought down to 20s. per ton crushed. In the days before the war one or two mines, like the Glencairn and Langlaagte Estate, where the conditions are favorable, worked for less than a sovereign per ton every month, but never before has the average working cost reached so low a point. Of course, there has been a big drop in the yield per ton, for as the costs come down the tendency is to work more and more of the lower-grade stuff, thus prolonging the life of the mine. In 1899 the grade was about 41s. with working costs in the neighborhood of 27s. per ton. In November last the grade was only 33s., but the working costs were about 20s. During November the profit per ton was as high as in July, August, and September, 1905, when the grade was 36s. The reduction of costs in 1907 compared with 1906 was about 2s. 6d., or 11%. We are still a long way from the 15 to 16s. per ton, which has been placed as the possible figure, but the substantial reduction in 1907 encourages the hope that still further economies will be effected in 1908. The future of Johannesburg, and to a great extent the Transvaal, depends upon the reduction of costs. All practical men now agree that there is a fall in grade as the mines get deeper, and the only way to make the 'deep deeps' possible is to get costs down to 15 to 16s. average.

The winner of the prize offered by *South African Mines* in the recent competition for small drills has been declared to be the Gordon drill. Much has been written in the local press over the success of this machine over the others, and if one were guided by the press solely, the day of deliverance for the Rand is at hand, and the ideal drill has arrived. The public has been very favorably impressed, and the London Stock Exchange has responded, for last week many of the dividend-paying stocks advanced considerably. That the Gordon drill will do good work seems probable, but whether it will revolutionize things is doubtful. The chances are that it will not be so satisfactory on the mines where very narrow stoping widths are imperative. On the West Rand, for instance, where the reef is very narrow, it is possible under favorable circumstances to carry the stopes from 20 to 24 in. when worked with Kaffirs. To make many of these stopes pay this width cannot be exceeded. Now it is doubtful whether the Gordon drill will be able to carry a stope less than 30 in. month after month. The vital question of comparative costs between stoping by hand and with the Gordon drill cannot be answered until more data are available.

The gold output for December constitutes a record for the Transvaal, being 583,526 oz., valued at £2,478,659. This is far and away better than the previous record, made in August last, when 555,027 oz. were turned out. The huge declaration for December is due to the fact that a number of the leading mines, in order to reduce their gold reserves, transferred a large amount from their reserve account. The December output brings the Transvaal yield for 1907 up to 6,451,384 oz., valued at £27,403,738. In December the Rand's contribution to the output was 562,684 oz., the number of mines producing this result being 66. Considering that there were five Sundays and the Christmas holidays, the results for the month are most satisfactory. There were 22 companies producing outputs of 10,000 oz. and over. As usual, the Robinson heads the list, with a declaration of 34,281 oz., valued at £145,616, while the Simmer & Jack came next with 24,798 oz., valued at £105,335.

As regards labor, at the end of December there were 110,337 Kaffirs and 35,676 coolies available for the mines of the Rand. So far the coolies have been successfully replaced by Kaffirs, but there are signs that in a few months time we shall feel the pinch of scarcity as regards native labor. Were an abundant supply of labor assured, the outlook for 1908 would be bright, but the Kaffir supply is so erratic that one never knows what a few months will bring forth. Of course the enthusiasts who never see any breakers ahead, declare that the Gordon drill will to a great extent solve the labor problem, and that the high level of gold production can be maintained, but this remains to be proved. It is to be hoped that 1908 will see an increased activity in the development of the deep levels and the 'deep deeps.' At the present time the Rand is like a clock that is wound up and set going. In eight or ten years time the clock will begin to run down and the glory of the Rand will be passed. It is necessary to get ready some of the deep levels to take the place of the rich mines, which cannot last forever. It is hoped that the improved conditions on the Rand, and the increased dividends being paid to shareholders, will induce a big flow of capital toward the Transvaal in 1908.

The largest wagon in the world has been shipped to Nome, Alaska, for the Pioneer Mining Co. It is over 26 ft. long and 7 ft. high from the axle. The wheels are 10 ft. diam. and are fitted with iron tires 1½ ft. wide.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

An electro-magnet has been successfully used in recovering a broken drill from the bottom of a borehole.

The dump of the new tin prospect near Spokane, Washington, is probably the biggest pile of tin ore in the United States. The association of minerals is an unusual one for tin ores and makes this occurrence unique. Although the deposit is irregular and indefinite, there appears to be sufficient ore developed to justify further exploration.

Assessment Work.—In regard to the work needed to be done on an amended mining location, it will depend somewhat upon the conditions existing at the time the amended location is made. If at such time all of the requirements of the law, State, Territorial, and Federal, have been complied with, and the amendment is made solely for the purpose of rectifying boundaries or curing technical defects in the notice, nothing further is required to be done, as in the absence of intervening rights the amended notice relates back to the date of the original, and location work previously done need not be again performed.

Various mechanical contrivances have been tried in southwestern Oregon in the separation of platinum particles from the black sand accumulated during placer mining for gold: the only successful method found is the simple one of panning. The material is panned twice, first for gold and then for platinum, over vats or huge tubs built for the purpose. To save platinum requires considerable care, as the particles are very light and elusive. The Deep Gravel mine in the Waldo district of Josephine county yields from 18 to 25 oz. of pure platinum every season. Probably the total production of southern Oregon mines in 1907 was about 50 ounces.

In most gold-quartz mines, the ore occurs in shoots and patches, frequently with a zone of enrichment by mechanical concentration at the surface, but usually as the vein is followed to great depth the gold contents diminish. This impoverishment is not always quite regular, and sometimes at great depths rich mineral is found. However, the deeper rich bunches in a mine are generally irregular and smaller than those near the surface. In the mines on the Rand in South Africa the fluctuations in value are less violent than in the usual quartz mine and the diminution of gold content in depth is a gradual one. It has become very serious at depths of 4000 ft. Less than 40% of the work done below that level has disclosed profitable ore. The best of the ore from the deeper levels would have been barely profitable in the early days of the field with their high costs and low percentage extraction: the Rand would never have reached its present position on ores similar to those disclosed in the deeper mines of today.

Cassiterite, the usual ore of tin, being an oxide, is not subject to rapid decay under weathering influences such as decompose sulphides; upon the wearing down of a tin lode the grains of cassiterite become disseminated in the soil. On a hillside the material slowly creeps down the slope and the grains of cassiterite gradually work to near the surface of the soil as do the gold grains in the 'traces' followed by prospectors in search of gold 'pockets.' Advantage was taken of this fact in investigating a tin lode in the valley of Lost river on Seward Peninsula, Alaska. Rows of small pits were dug 1 to 2½ ft. deep (at which depth frozen ground was reached), and some of the material was washed in a gold-pan. This process revealed the existence of a distinct 'trace' of cassiterite, which led up to the outcrop of a small shoot of ore already developed by adits; the benefit of the work lay in the fact that the absence of much cassiterite in the soil below the tin-bearing dike elsewhere precluded the probability of other ore-shoots being distributed along the lode and discouraged further expensive and useless development work.

Lead-silver veins usually have a zone of oxidized ore near the surface; at greater depth is the zone of original sulphide ore, which is generally an argentiferous galena. In the oxidation of the galena, the sulphide is first changed to sulphate and then to the carbonate, cerussite. The latter is slightly soluble in the water circulating through the zone of oxidation, and some of the lead salt must be leached out and carried to a deeper portion of the vein or elsewhere, perhaps finding its way into the streams of the district. The silver salts are subject to a similar leaching. However, it is a matter of observation in arid regions such as those of Nevada and Arizona, that while the lead and silver have largely disappeared from outcrops of the vein matter, the strongly leached zone is very thin, often only a few feet deep; profitable lead carbonate ores are generally found to within 5 or 10 ft. of the surface. The wall-rock, whether limestone, slate, or some crystalline igneous rock, can have very little influence on the oxidation and leaching of the materials in the vein, except that as limestone near the surface is generally more cavernous than other formations, it favors the deep penetration of the weathering agencies. In Arizona in a strong vein which cuts Archean gneisses and granites there is such a progressive increase in the mineral contents from the surface to where the sulphide zone appears, at an average depth of several hundred feet, as to suggest leaching near the surface. In this vein, as also in many others, there has been a secondary concentration of the silver salts into bodies of high-grade ore within the oxidation zone. As a general rule it may be said that if a lead-silver vein in the desert region does not contain any profitable ore within 10 ft. of the surface, its chance of developing into a mine at depth is very slight.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Plumas-Eureka Mine.

The Editor:

Sir—Your notes under 'General Mining News' concerning Plumas county, California, in the current issue (Feb. 1) are somewhat misleading, and as the Plumas-Eureka mine has played no small part in the history of gold mining in northern California, its mining and milling costs being quoted in several standard text-books, I thought perhaps people who knew the old mine in its palmy days, would be interested to know what steps are being taken to place it once again upon the list of gold-producing properties.

The mine was purchased by its present owners, the Johnston Graham Mining Co., in the spring of 1905, but very little was done toward re-opening the property until the summer of 1905. After a careful examination and sampling of those parts of the property it was possible to reach, it was decided that the easiest point of attack and the one most likely to yield quick returns was the Seventy Six mine. The Hosking cross-cut, the lowest opening into the Seventy Six workings, was cleaned out and an aerial tramway by the Broderick & Baseom Rope Co. installed, connecting the mine with the mill-building, a distance of about 1000 ft. vertically and 3400 ft. on the incline below. The old mill-building, which was in a state of great dilapidation, was renovated and a new 20-stamp mill of 1000-lb. stamps furnished by the Fulton Iron Works was erected. The Jamison flume, four miles long, has been rebuilt for the greater part of its length, and the remainder roughly repaired. A commodious boarding-house has been erected on the banks of Eureka lake for the miners.

The work in the mine has been confined entirely to development. This policy will be necessary for some time, as prior to the present company taking hold, the mine had been let on a series of short leases to tributers, apparently without any restriction; and they had naturally taken every particle of available ore that would pay for transportation to the mill down the old tortuous series of inclined and horizontal tramways. Development work has been confined for the present to three veins, the South vein underlying the Balten tunnel vein in a southerly direction and the Balten tunnel cross-cut vein, and an overlay of the same, in a northerly direction. All work is being prosecuted from the level of the Hosking cross-cut.

Five stamps were started in November of last year, and five more in the middle of December, since then 10 stamps have been dropping continually, from ore taken out in the process of development. With the exception of a few promotion shares owned by Western people, who were instrumental in bringing about the sale of the property, the mine is owned by Newport (Rhode Island) people, who have found the money for the construction and development work, without seeking any newspaper notoriety. Just after the purchase of the property an article appeared in a San Francisco paper, written by someone whose enthusiasm was considerably in excess of his knowledge of either the mine or the science of mining; with this exception, so far as I am aware, no boom articles have been written about the property nor are any required.

In conclusion I may add that the note with regard to the Little Jamison mill should read the Jamison mill, which, after being temporarily closed down on account of shortage of water, is again running. G. S. Redstreak is superintendent and S. W. Cheyney the consulting engineer.

Johnsville, California, February 4.

Prospecting With the Diamond-Drill.

The Editor:

Sir—For those undertaking core-drill prospecting, the following examples may be of interest in showing some of the errors to expect, especially where results are confined to one hole.

In using drills one cannot be too careful, both in laying out the work and in sampling both core and sludge. Some years ago in one of the old camps a drill-hole was put down in ground supposed to be on the continuation of a very large ore-shoot, the writer having the contract for the work. At a depth of about 500 ft. a contact was encountered and immediately under it there was ore. According to the drill results, 10 ft. of ore was in the hole. The ground was soft and made little core, and that in small pieces. In passing these 10 ft. of ore, samples were taken of both sludge and core every 2 ft., all the core obtained being ore. At the same time underground waters were carrying away most of the sludge, there coming to the surface about an equal amount of it as of the core, the resulting sample being small. The whole 10 ft. drilled the same way, no change being noted in the working of the bit in the hole. On the information given by this hole, a shaft was sunk at a large expense, much water being encountered. When the ore was reached it was found to be in small seams throughout the lower 10 ft. of the contact, but not in paying quantity. The expense of sinking this shaft was borne by intelligent and successful mining men, who went into the scheme with the utmost assurance of success. In the shaft the seams of ore were found to be slightly harder than the enclosing rock, which accounts for only ore being in the core. Another source of error is when using a drill for cross-cutting for veins. In places where the country rock carries seams and stringers, if the vein happens to be cut in a tight narrow place, it is impossible to tell which is the vein. This is also true of a drift in a mine, but in that case one can generally see some distinguishing signs of the vein looked for. In cutting a vein it is often the case that the drill will not determine the actual width, as vugs or irregularities in the walls cause the operator to think that the bit is still in the vein. Ground rarely gives all core, the pieces grinding against each other in the core-barrel causing a partial loss of the core. There is no way of getting at

the exact width of a vein except by the action of the drill when working. These are all cases seen by the writer that have caused losses, and when there are so many sources of error in using drills, every precaution possible should be used in order to get accurate results.

R. B. WEDDLE.

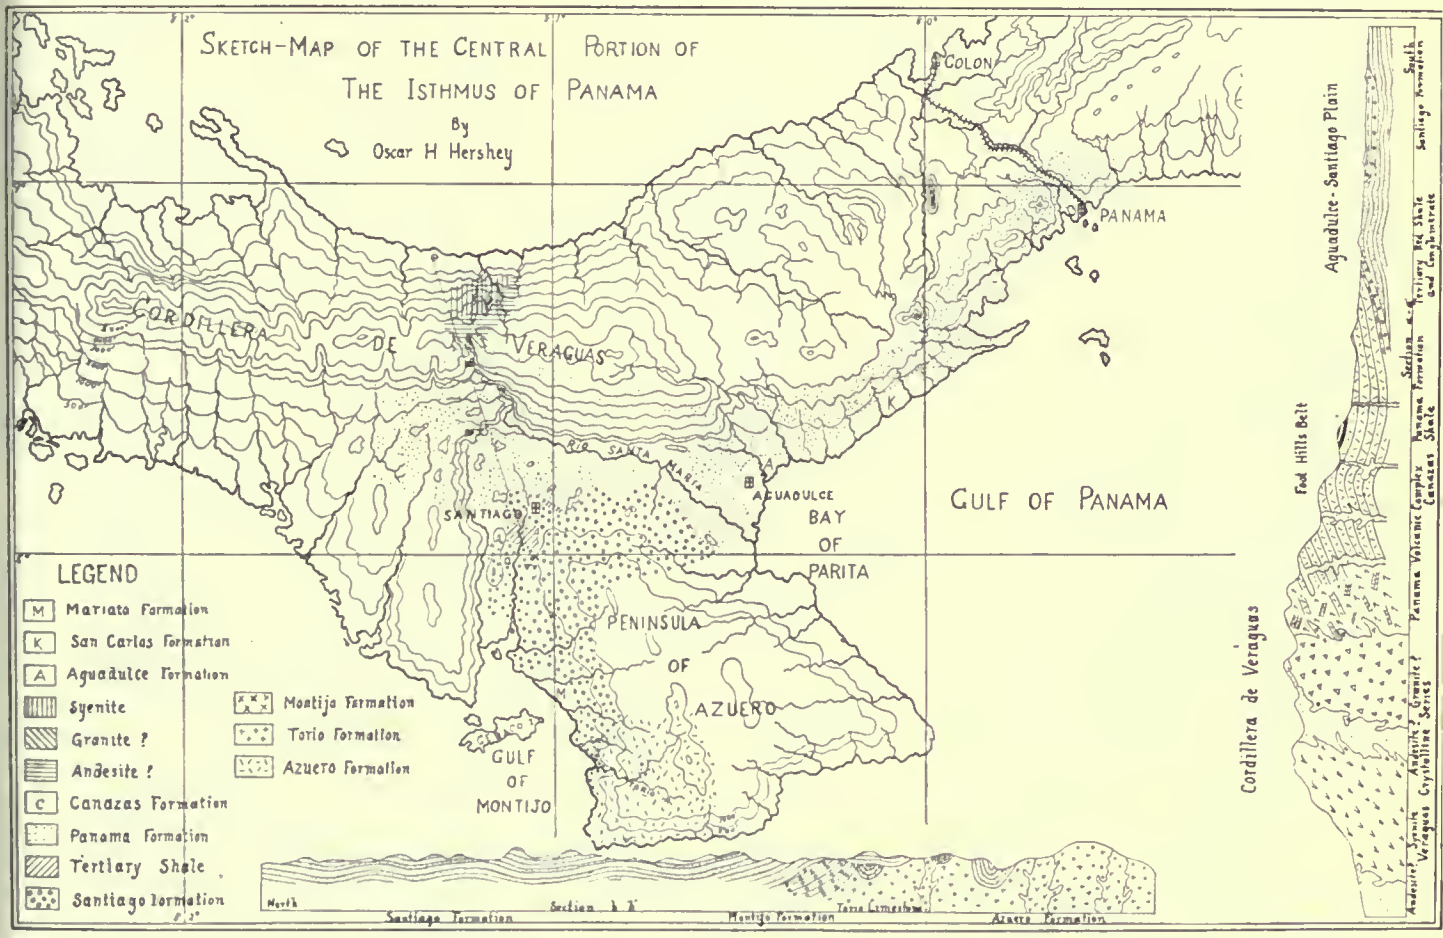
Dehesa, California, January 25.

Mining in Panama.

The Editor:

Sir—The geology of the central portion of the Republic of Panama is much more complex than it has been described by Mr. Scott Turner in your issue of January 25. Andesite probably plays a relatively unimportant rôle in it. I have discussed at considerable length the geology of the districts about Aguadulce, Santiago, and Cañazas, in No. 8, Vol. 2, Bulletin of the Department of Geology of the University of California. Aguadulce is situated on a Pleistocene sedimentary formation and Santiago is near the northern border of a much older sedimentary series. The village of Cañazas and the Remanse mine are in the midst of a broad belt of the Panama series of volcanic rocks. In the southern half of the belt the Panama formation is chiefly water-laid rhyolitic and trachytic tuffs intruded by plugs, dikes, sills, and laccolites of diorite, andesite, basic porphyries, and basalt. North of Cañazas and the Remanse mine the basic intrusives make up a large part of the entire formation and the volcanic rocks in general display much less evidence of water deposition. However, a small area of sedimentary rocks occurs within several miles east of Cañazas. The high jungle-covered range of the Cordillera de Veraguas lying north of the volcanic belt is composed largely of plutonic rocks, including an alkaline granite and a syenite; these may have been intruded into a finer-grained dark gray rock that has been doubtfully identified as andesite.

Probably the most promising undeveloped district in the Veraguas country lies within the area of plutonic rocks on the northern side of the Cordillera de Veraguas. It is known as the Mineral Veraguas district and includes the old drift mines of Cocuya, gold from which has been the basis of several Colombian fortunes. It was discovered over



350 years ago and mining prosecuted in it, first by the Spaniards and Indians and later by the Colombians until about 24 years ago when it was finally abandoned by the last inhabitants, Angelo George, an Italian, and his Indian helper. This was not because it was worked out, but on account of the severe conditions. It was situated in an almost impenetrable jungle and in a region where rain falls on nearly every day in the year. At the time of my visit in 1898 the old workings were obscured by the dense growth of vegetation, but I was fortunate in having the services of Angelo George as guide. Two small veins of gold-bearing quartz had been accidentally discovered in the course of placer mining and a French company once made an attempt to work them. I found the ruins of a 16-stamp mill and two arrastres; also a pile of quartz that yielded well in panning. However, the one vein that I found was very small and I concluded the operation had been ill advised. A favorable impression was made

by the great number of rough fine grains of gold that I could save in the gold-pan from the gravel and sand along the Santiago river. As I was fresh from panning the gravels of many California rivers and creeks, I had a good basis for comparison. The gold grains were identical in character with those I had often panned from the outcrop of gold-quartz veins in California. They were so abundant that I was convinced that only a small part of them had been derived through the decomposition of the few small veins that had been discovered. The half-mile of steep mountain gulch between the head of the Santiago river and the highest point at which I panned is the most promising place I know in which to apply the Californian method of searching for gold-quartz veins by the aid of 'traces' of gold in the dirt. The Spaniards, Colombians, and Indians knew nothing of this method. At one place, half-way up the slope of a mountain, they worked the soil over several acres for the fine-grained gold they could get from it. The pits and mounds remaining terminate on the upper side of a comparatively straight line; perhaps a valuable vein is buried under the soil not far above this line. I do not make these statements with the object of attracting prospectors to that locality, for they would be helpless in coping with the jungle. Further, the average mining engineer would be unfavorably impressed, for the country has returned practically to its primeval condition and there are no mines to see. It is also true that the gold in the placers may have come from innumerable seams instead of a group of large veins. Similar fine-grained gold is abundant along other streams of the region, particularly the Bijuco river.

Mr. Turner is keenly appreciative of the difficulties encountered by mining companies that attempted to operate in the comparatively dry region south of the great range, in their poor management, and in their almost invariable failure.

OSCAR H. HERSHEY.

Berkeley, January 27.

Cyanide Methods.

The Editor:

Sir—In your very courteous and most appreciative editorial of January 4 you refer to me as being interested in the manufacture of the Ridgway filter and therefore (?) pardonably partial to it. I am interested in the Ridgway filter, as I am in the Merton roaster, the Dehne filter-press, the Davidsen tube-mill, and other valued appliances for improving extraction. Indeed, such an interest is not merely desirable from a pecuniary point of view but is necessary to me for the securing of absolutely reliable data and for following up the results of different appliances under differing conditions. But you appear to misinterpret cause and effect. My interest in the Ridgway is the result of my appreciation of it, and not vice versa. Thus it will be news to you that my interests in the two other methods recently prominently discussed in your columns is probably much greater than in the Ridgway. I do not own the Ridgway patents, but I do own the patent in America for the filter-frame which has probably treated a greater tonnage by the immersed basket-filter method (Moore process?) than have the Liberty Bell and all the other mines (using this process) in America put together. Again, I also own the Thompson (1899 Transvaal) and other patents for fixed immersed suction or pressure basket-filters. These patents appear to me to be the master patents of the majority of the devices now on the market; but my ownership of these patents does not blind me to an appreciation of the Ridgway filter any more than did my interest in Dehne filter-presses, to which the Ridgway machine is in opposition.

ALFRED JAMES.

London, January 30.

Cyanidation in Nevada.

The Editor:

Sir—The discussion started by Mr. Browne has borne good fruit in that it has elicited the able and comprehensive article by Mr. King appearing in your issue of January 25. The method of treatment of Goldfield ore advocated by Mr. King is not in any sense experimental and has proved to be best in West Australia, where the conditions as to high cost of power, water, and fuel were similar to what they now are at Goldfield. The same method is in use at the Golden Cycle mill, where they treat Cripple Creek ores. This mill is a custom plant depending on the extraction and economy of treatment for its profits, and works ores for a freight and treatment charge of $4, of which $1 is freight. At Mercur they mine and mill their ore for a few cents over $3 per ton. The tests made by Mr. King, the results of which are given in his article, prove that Goldfield ores are perfectly suited to this method of treatment and it is difficult to understand what objections can be held against it.

It is reasonable to state that the best method is that which extracts the gold in one treatment and with the simplest machinery. The mills in Nevada, however, seem to be designed to extract the gold and silver in as many forms as possible and each one may be said to be an epitome of the history of ore treatment. Amalgamation followed by concentration and then by cyanidation represents the order in which these processes came into use and is the order in which they are used in the mills.

Regarding amalgamation, Mr. King's results show an extraction of only 4.2% by amalgamation on the raw sulphide ore. On the roasted ore the extraction by amalgamation was 44.67% and subsequent concentration and cyanidation brought up the total extraction to 97.17% at 30 mesh. Direct cyanide treatment at the same mesh yielded the same extraction. His further results at 100 to 150 mesh show that the gold in the roasted ore is quickly and completely dissolved by cyanide. These results tend to prove that, contrary to the general belief, roasting does not cause the gold to become coarse or run into beads when the telluride is decomposed. Gold telluride melts at a low temperature, below a red heat, and when a rich specimen of telluride ore is roasted, the melted telluride runs out on the surface and the tel-

lurium is oxidized, metallic gold being left. This gold looks exactly as if it had been melted, but on examination it is found to be porous or spongy. I once took a piece of this porous gold resulting from the roasting of a rich specimen of Cripple Creek ore and placed it in an ordinary 1% cyanide solution and found that 70% of it was dissolved in a couple of days. However, as Mr. King has shown, in the case of a rebellious ore that actually did contain coarse gold, grinding the roasted ore to 100 mesh resulted in a practically complete extraction of the gold by cyanide; the presence of some coarse gold is a matter of no importance when fine-grinding is done. My answer to the question of 'Viator' regarding the treatment of ore carrying coarse gold as well as fine gold is, therefore, that, when fine-grinding is done, the coarse gold will be ground fine along with the gangue and dissolved in the cyanide without any difficulty. Owing to the great cheapening of the cost of fine-grinding by the use of tube-mills and the improvement in the filtering and washing of the fine pulp by modern filter-machines, fine-grinding will be used in the majority of mills. Amalgamation will be unnecessary and only a needless expense. In the few instances in which it may be better to extract the coarse gold by amalgamation, amalgamation should follow cyanidation and the processes should be kept separate.

As regards the roasting of ore in localities where fuel is expensive, some means should be adopted to reduce the cost of the fuel. When it is remembered that the roasted ore is discharged from the furnace at a temperature approaching 800° C, it is obvious that if a fair proportion of that heat could be returned to the furnace, an economy in fuel would be effected. In all cases the hot roasted ore passes through some cooling device, but it is generally some water-jacketed arrangement, and the heat abstracted from the ore is lost. It would seem to me that a simple heat-exchange device could be used by means of which the ingoing air could take up a portion of the heat from the outgoing roasted ore and so return it to the furnace. By extending the hearth a sufficient distance beyond the finishing hearth and by keeping the arch as low as possible, the air entering the furnace at the discharge end will abstract the heat from the hot roasted ore. The economy effected by the return of this heat to the furnace will amount to about 25%, but there is the additional advantage of using pre-heated air for the combustion of the fuel. In a modern lime-kiln where the air is pre-heated by means similar to the above, an economy of 30 to 35% has been attained.

It has been the practice in chlorination works for a number of years to crush only to 10 or 12 mesh before roasting and to grind as fine as required after. This is, for many reasons, the best practice and I think the principle should be further extended. Preliminary tests should be made to determine how coarse the ore could be left compatible with getting a 'sweet' roast in a reasonable time. In the majority of instances this will be found to be much coarser than is generally supposed and possibly a quarter-inch size will be found fine enough. Drying of the ore would only be necessary in exceptional cases and the crushing could be done cheaply by jaw-crushers. As roasted ore is much more friable than raw ore, this would mean a big reduction in the total cost of crushing and grinding. The decrease in the tonnage to be ground for the same output of bullion (owing to the loss of weight in roasting), the greater friability of the roasted ore, and the advantage in filtering of having a pulp free from hydrated silicates should be credited to roasting and the saving effected deducted from the cost of roasting as compared with the treatment of the raw ore.

With the greatly increased use of fine grinding during the last few years the filtration of the pulp has become a question of increased importance and has brought forth a large number of filter-machines, all of them using canvas as the filtering substance. As referred to by Mr. King, the incrustation of carbonate of lime on the canvas is a great drawback, and I am reliably informed that at the plant of Mr. Charles Butters at Virginia City, two men are employed all the time to take out the filter-leaves, treat them with acid, and return them. To the majority of people a sand-filter consists of, first, a layer of coarse gravel, then one of fine gravel, then one of finer gravel, and then one of sand, in all about a foot or so thick. The impression is also general that fine slime will pass through a layer of sand. The fact is that a layer of clean sand an inch thick will, if properly supported, form an efficient filter for the finest slime. I first used the triangular-slat-sand filter in 1888 for the drainage of sewage sludge. In 1894 these filters were put in the plant treating tailing from the Vulture mill at Wickenburg, Arizona. They remained in constant use for about two years and were cleaned not once during that time. One advantage of a sand-filter is that the filtering material is always on hand at the mill. When canvas is used a large stock has to be kept on hand and much inconvenience may result from the delay of an expected shipment.

Mr. King's article is especially valuable in that it gives the results of original work carefully and systematically performed, and it is to be hoped that others will publish results that they have obtained to the improvement of this branch of metallurgy.

BERTRAM HUNT.

San Francisco, February 5.

The Editor:

Sir—Referring to Mr. Lochiel M. King's article on this subject in your issue of January 25, I do not doubt the presence of tellurium in small quantity in the high-grade ore from the Mohawk mine of the Goldfield Con. Mines Co. In fact, I stated as much in my communication (issue of January 11). I still maintain, however, that there is not enough tellurium present in the milling ore now exposed in Goldfield (in the properties of the Goldfield Con. Mines Co.) to interfere with milling treatment by wet methods; and that the tellurium found in the higher-grade ore from the Mohawk mine is not in sufficient quantity to justify roasting in a large mill designed

to treat milling ores from all of the Consolidated properties.

EDGAR A. COLLINS.

Tonopah, Nevada, February 6.

National Mining Bureau.

The Editor:

Sir—In the issue of the MINING AND SCIENTIFIC PRESS of February 1, I note that you have placed before your readers a part of the letter addressed by me to the Secretary of the Interior on the subject of more extensive recognition of the mining industry by government investigation. In my letter of January 18, enclosing a copy of the letter to the Secretary, I authorized you to use any portions of it, and added that "after working for twenty-eight years in the interest of the mining industry the Survey will not, of course, oppose what may seem for the good of that industry." That is the point of the letter, and the position taken by the Survey is clearly outlined in the last paragraphs. I am very sorry to see that you have omitted them. The Survey earnestly wishes to place itself on record before the mining men of the United States as to its recommendations in this case. As the letter is printed in your paper of February 1, considerable uncertainty must be felt by the reader as to the actual proposals made. This is much to be regretted, as special care was taken to make this matter perfectly clear in these closing paragraphs. I think that as long as the remainder of the letter has been printed it would be only fair to ask that you should state the position of the Survey by publishing the last part of the letter.

GEO. OTIS SMITH.

Washington, February 8.

[This letter from the Director of the Geological Survey was received just as we were going to press last week. His request had been largely anticipated by an editorial statement in regard to the attitude of the officers of the Survey and a brief quotation from Mr. Smith's letter.—EDITOR.]

Closing paragraphs of letter from the Director to the Secretary:

"To meet the actual needs of the industry, the time is opportune for the enactment of well considered legislation and I submit herewith the draft of a resolution which in the opinion of myself and associates in the Survey is adapted to accomplish the desired end. My purpose is to suggest legislation that will adequately provide for an increase in the mining work by the Federal government without duplicating that already authorized. Some plans already presented for a Bureau of Mines have contemplated taking over much or nearly all the work of the Geological Survey; others have confined the proposed Mining Bureau's activities to the more purely technologic problems together with the statistical work.

"It appears to me that there is only one true line of cleavage between these subjects, and this lies between the pure technology and those matters relating to the distribution, occurrence, origin, and production of mineral deposits. Those who advocate the turning over to another organization the statistical work of the Survey have little comprehension of the true character of these investigations. As now carried on, this work embraces not only the tabulating of the statistical information, but also the discussion of the source of the materials themselves.

"On the basis of the historic development and present status of Federal work in aid of the mining industry of the United States, the limitation of the function of any organization independent of the Survey to strictly technologic work is in my opinion absolutely essential if duplication of work and rivalry are to be avoided. To the same end I wish to place great emphasis upon the importance of having the name of the organization such as to express its functions and those alone. The word 'mining' in itself would be inappropriate for investigations which form a part only of those relating to mines and mining. With this in mind I submit herewith a draft of a joint resolution providing for the establishment of a Mining Technology Branch in the Geological Survey, the passage of which would constitute a decided gain in the expansion of the mining investigation by the Federal government.

"If, however, in the opinion of Congress, conditions are favorable for the realization of the proposition for an independent organization, it is my belief that the bill establishing such a bureau should provide not for a bureau of mining, but for a Bureau of Mining Technology. I therefore submit the draft of a bill which provides for the establishment of an independent bureau to which the work now under the Technologic Branch of the Geological Survey could be transferred. Such a bureau would supplement along purely technologic lines the geologic work of the Survey in behalf of the mining industry.

"In the event of the passage of the joint resolution first mentioned, my endeavor would be to so administer the added work as to promote the possibility of its ultimate establishment as an independent bureau whenever found advisable, while if the bill for the creation of a separate bureau should be enacted, the Geological Survey would co-operate with the Bureau of Mining Technology under your direction."

A Correction.

The Editor:

Sir—In the article describing the electrical hoisting equipment of the Kendall Gold Mining Co. of Kendall, Mont., and appearing in your issue of January 11, you have given credit to the General Electric Co. for the entire equipment.

We desire to inform you that the double-drum hoist used in this installation was built by us for the mining company mentioned. The electrical equipment was furnished by the General Electric Co. As this installation at Kendall is the latest improvement in hoisting equipment, and is also the first of its kind installed in the United States, we naturally desire to have credit for our share in it.

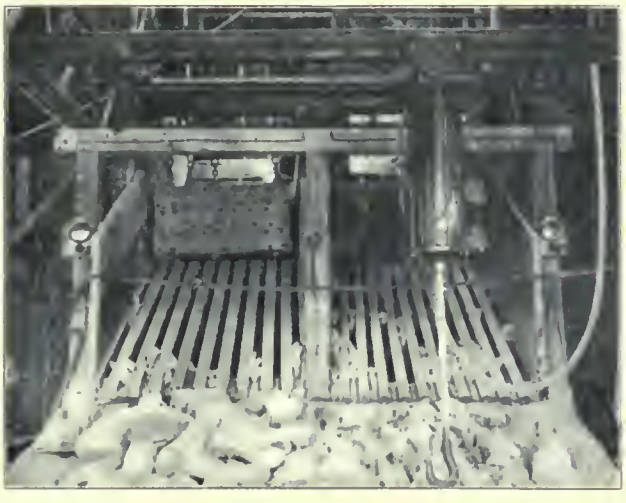
THE DENVER ENGINEERING WORKS CO.,
LEWIS SEARING, General Manager.

Denver, January 30.

LAKE SUPERIOR ORE-DRESSING PRACTICE.

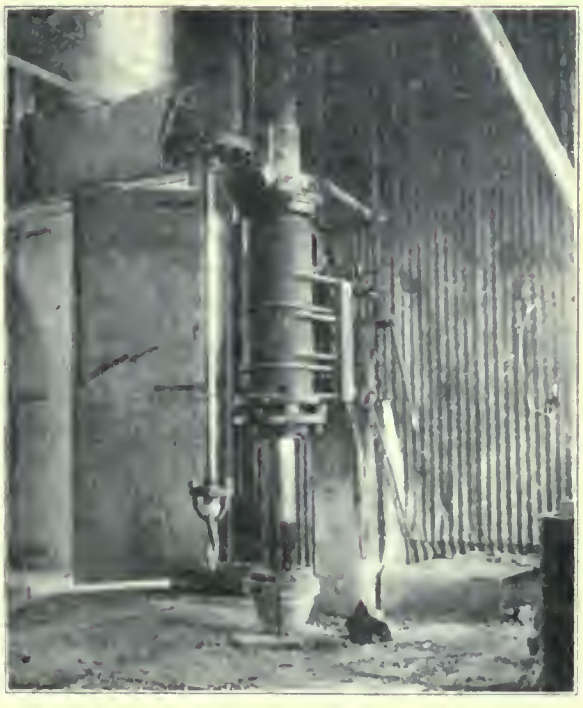
Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

Steam-Stamps.—The tendency during the past year has been toward the increased use of the compound head, because of its economy in steam or the horsepower per ton of the ore stamped. While this is true, there is less increase in the use of the



Grizzly at Trimountain No. 4 Shaft.

type than was at first anticipated. There are critics who think that the drawbacks, due to the larger quantity of oil and waste needed, the additional supplies for repairs, the repairs account itself, and



Air-Lift and Hammer.

the delays caused both by repairs and by breakdowns, more than compensate for the economy in steam. The labor item is also greater, since a head-runner is needed for each head, while with simple heads one man can attend to three. To retain the feature of simplicity, the Quincy mill has put in a 24-in. simple cylinder in place of the usual 20-in., has dispensed with rolls for re-grinding the oversize from the trommels, and has increased the capacity of the head to 700 tons in 24 hours. At the Calumet & Hecla mill they have added no others to the first compound head erected. On the other hand, the new installation of the Champion mill includes compound heads, and they have added three at the Centennial mill at Rouse's Point, thus doubling the original equipment of three heads.

45-lb. Ingots of Copper.

Rolls.—The favorite style seems to be the springless rolls, though at the Champion spring rolls have been placed, having a contrivance for parallel opening. Where springless rolls are used, a grating in the feed-chute excludes any possible bolts, pick-points, or hammer heads. The feed contains nothing larger than $\frac{5}{8}$-in. diam., so that, even when these pieces are of copper, they are readily flattened, screened out, and removed by the bull or roughing jig. The wooden key was at first inserted for the

Mass Copper at Champion Mine.

main driving pully to prevent stalling the rolls, but, since it was too readily sheared with a suddenly increased load, it has been replaced by an iron key, risking thus the remote chance of stalling or breaking. The rolls are estimated to relieve the stamps to the extent of 200 tons daily in their duty of crushing the oversize of $\frac{3}{4}$ in. from the trommels,

the undersize going to the main system (or 'wash') of the mill.

Re-crushing Middling.—Of the two kinds of mills, the Huntington and the Chilean, both of which have been tried here, the latter has been adopted at the Calumet & Hecla in the new re-grinding plant. The claim has been made that its action, which is a twisting, as well as a direct-rolling, is not an objection in the treatment of the conglomerate rock where sliming does not hurt. As is well known, the copper in this ore is so closely knit that fine grinding gives the best results, even when accompanied by some sliming. No attempt has been made to use the tube-mill in Lake Superior practice, though we have an example of one in the district, used however for the grinding of sand in making lime-brick. Considering the cheapness of the wearing surfaces in the tube-mill, it would appear that it could be adopted with a great saving for repairs and for castings.

Jigs.—The Woodbury jig is coming increasingly into use, and is being put in at the Champion after having been thoroughly tried in the Calumet & Hecla mill. Arranged as a series-jig it has large capacity, acts as a screening system, and separates out an overflow for classification.

Classifiers.—The roll product is conducted to single compartment classifiers, having a pyramidal bottom, and using hydraulic water. The overflow goes to tables, the spigot-discharge to jigs. The hutch-product from these jigs goes to finishing jigs. On the whole, classifiers in Lake Superior practice are imperfect, and would not be tolerated except in treating an ore where there is so great difference in specific gravity between the concentrate and the gangue. The four-spigot Tamarack classifier is imperfect in that any given spigot-discharge is contaminated with coarser and finer grains properly belonging to other spigots or to the overflow. The first spigot is also apt to discharge most of the jig-stuff, leaving but little for the later jigs to treat.

Tables.—The Wilfley concentrating table holds its own, and the more so as its use has become familiar. It, or some equivalent table of the same type, is used for concentrating Evans-table heading so as to obtain a high-grade product.

Schwartz has devised a roughened or grooved sheet-lead covering for the Wilfley table. These grooves are shallow, 20 to the inch, and run parallel to the long sides of the table. They assist in the elimination of the finer gangue, and in bringing the fine concentrate under their shelter to the discharge end of the table. It has been found that the grooves are disposed to fill up and coat over, and it is proposed to overcome the defect by copper-plating the surface.

Companies in the copper country have been willing to expend money in experimenting with apparatus, and in introducing improvements, often at great expense. Their methods of ore-dressing have often been criticized, but it must not be forgotten that with such low-grade ore, of which large tonnages must be handled, they are unwilling to supercede methods that have done good work in favor of new but untried plans, no matter how good in principle. An example of such liberality may be given in the case of the Champion mill, where a graded-crushing system, involving the use of rolls, was tried for an entire year. It was hoped to make an economy in power, and especially to effect a closer saving than in the old way. However, the greater complication of the system, and the equal losses in tailing, resulted in a decision to tear out this equipment and replace it with stamps. At this mill the present plan is to use thoroughly constructed compound stamps in connection with Woodbury jigs, large settling-tanks with goose-neck spigot-discharge and Deister tables.

The Alpha Shaft Accident.—Three miners were entombed on Dec. 4, 1907, in the Alpha shaft of The Giroux Consolidated Mines Co. in the heart of the low-grade copper deposits near Ely, White Pine county, Nevada; on the evening of Jan. 18 they were rescued after 45 days imprisonment 1000 ft. below the surface. Four men were working on the morning of Dec. 4 at the bottom of the 1085-ft. shaft and the pumpman was at the pump-station on the 1000-ft. level. When the cave started the men attempted to gain the upper level by climbing the ladders through a shower of timber, rocks and earth that fell about them. Two were knocked back and killed, but two reached the pump-station safely. While the shaft was caving, the pressure in the steam pipes was flowing the station full of fine dust; the pumpman telephoned the engineer in the shaft-house to shut off the steam pressure and immediately afterward telephonic communication was interrupted. Later, at the direction of the mine electrician, the instruments were connected to the power cables running to the electric pumps, and thus telephonic service was restored. In the meantime a 6-in. water-pipe was used as a speaking tube. The imprisoned men took a gate-valve and several feet of pipe off this line, allowing food, water, candles and reading matter to be lowered and received. The mine master mechanic devised a train of 12 carriers made from 2-in. pipe nipples and caps, connected together with eyebolts and flexible connections. The 6-in. pipe when not in service for lowering food, water, etc., was used for the air supply; an attempt to furnish compressed air through the steam-pipes merely blew dust into the station, owing to a break in the line. The imprisoned men did not suffer much from cold, but the dust and dampness produced discomfort. They kept the drift well lighted with candles and were able to take exercise by walking back and forth in it. During 46 days the work of rescue was pushed as rapidly as possible. A considerable portion of the shaft was found so filled by a rammed mass of timbers, rocks and earth that clearing was difficult. Finally an open space was found leading from near the 700-ft. level to within 30 ft. of the imprisoned men; the material below this opening was largely fine dust, and the men aided in their rescue by letting this dust run into the drift and shoveling it back.

A THEORY OF ORE-DEPOSITION.

Contributed to the MINING AND SCIENTIFIC PRESS
By J. E. SPURR.

*It is the correct procedure in scientific literature to present evidence in detail, and then the conclusions to which, in the mind of the writer, that evidence has led. In the present instance, I should like to be granted an indulgence, and present, baldly and in the barest outline, a theory or series of theories, leaving the presentation of the progressively built steps of evidence till a later time. It should be stated, however, that the ideas as stated are not imaginative, except in the logically legitimate sense: they represent the total inductive results of the writer's experience, pieced together so as to form a working hypothesis.

This paper has been written hurriedly in the field, under stress of work, without notes or references of any kind; and allowance should be made for the absence of citations from the writings of others.

Portions at least, if not all, of the solid crust of the earth are underlain by fluid and uncrystallized rock magmas. These magmas represent, prevailingly or entirely, what are known to petrographers as intermediate types. They differ, however, in different sub-crustal regions. These differences, expressed by certain ratios of the relatively common rock-making elements, have given rise to the recognition of petrographic provinces. More delicately and unmistakably (as in all classifications) the differences are expressed by differing amounts and ratios of the less common elements, among which are to be reckoned most of the metals; and these differences have led to the recognition of metallographic provinces, a conception of especial importance to the economic geologist, whose investigating problems bear chiefly upon the distribution of the metals in nature. The origin of these differences in uncrystallized and uncrystallizing rock magmas is unknown.

By intrusion, or erosion of overlying rocks, or both, portions of these intermediate magmas are (at apparently irregular intervals and on account of obscure events) brought within the zone of incipient crystallization. Crystallization commences, minerals being deposited in an orderly succession dependent upon the chemico-physical laws of magmas (which differ from those of dry melts). Roughly speaking, iron, lime, and magnesian silicates are first precipitated, then silicates of the alkalis, and, finally, the residual silica.

In the lower part of the zone of crystallization, this process of consolidation extends over a vast period of time. Meantime forces (largely physical) are at work tending to concentrate like and similar minerals. Such cooling magmas must be subject to oscillations and currents due to crustal movements and changes of pressure and temperature; to convection and to specific gravity. These currents tend to 'classify' the magma (to borrow an illuminating technical term from the science of ore-dressing) according to the specific gravity and size of the crystallized minerals, and the specific gravity of the residual fluid magma. By specific gravity, also, similar minerals and minerals of similar weights, become concentrated in still magmas.

In such solidifying magmas, currents set in motion at any stage of the crystallization may drain off the residual fluid, leaving the already formed crystals massed together to make up the greater part of the solid rock; or often a different (chemically) residual fluid may be substituted, from whose crystallization the final rock fabric is completed. The evidence of this last-described condition is found in certain of the phenomena of magmatic resorption, where earlier-formed crystals find themselves, through accidents like those above suggested, in a changed mother liquor in which they are unstable and are partly or entirely dissolved.

It follows that the residual fluid magma, drained off from the crystallized portion, at any stage of crystallization, may preserve its identity till its own crystallization period arrives, or may in turn, on partial crystallization, undergo the subtraction of the still fluid portion; so that rocks representing all the stages of crystallization, as well as others representing many different combinations, result.

Through this long and intricate period of orderly crystallization, and orderly sorting, it results that the rocks solidified from a single magma are of many different kinds, mineralogically and chemically; that phases are common where the minerals represent the first stage of consolidation only, or the last stage of consolidation only; that rarer but still frequent phases are found where the rock is principally composed of a single mineral; and that, obscuring the evidence of these clean products of concentration processes, apparently anomalous rock-types occur, in which usually unsociable minerals are associated, such types representing in many cases, probably, physical mixtures of partially concentrated sub-magmas. That concentration of like or sociable (for chemical or physical reasons) minerals, actually takes place in many magmas, in deep-lying zones now revealed, by erosion, at the surface, is recognized by geologists; the unmistakable evidence of it can be read in outcrops in numerous localities; and in some cases it can be proved that the secret of this rock differentiation lies in the slow successive crystallization, the draining off and migration of the successively residual fluid, and the consequent massing of the crystallized portions.

According to this hypothesis, the normal succession of sub-magmas, emitted from a solidifying magma reservoir and consolidating as intrusive or extrusive rocks, should represent a progressive change from less silicious to more silicious rocks; or, as it has usually been stated, from basic to acid. This is actually the succession recorded for certain igneous centres by some of the best geologists; and it is the history to be read on many exposures of originally deep-seated granular igneous rocks. If, however, the heat and pressure conditions, instead of remaining uniform, were fluctuating, then in the reservoir of consolidating magma rocks would, after partial or even entire consolidation, be reduced to a

*From advance copy of a paper to appear in *Economic Geology*.

liquid condition; and this would happen many times in succession. With each wave of increased heat the mass of segregated (differentiated) crystallized, semi-crystallized, and still fluid materials in the magma reservoir would be transformed into a complex of differing magmas, and in each magma phase with each downward swing of the temperature the process of further segregation by progressive crystallization, accompanied by mechanical and chemical concentration would continue, bringing about more perfect differentiation. Thus materials emitted from time to time from such a reservoir would show a progressive change from the original intermediate magma, to more silicious and less silicious magmas; and this is actually the observed succession of both intrusive and extrusive rocks near many igneous centres.

The above hypothesis assumes that rock magmas do not begin to differentiate until they are subjected to unusual or catastrophic conditions;† that these conditions are supplied in magmas which occupy the lower portion of the zone of crystallization, where consolidation is very slow and may be interrupted by fluctuations of heat and pressure; and that under such conditions, from an intermediate magma, rocks and rock magmas varying from very silicious to very basic may originate.

It has been stated that in the succession of crystallization, as a rule, minerals high in magnesia, lime, and iron are precipitated first; and those high in silica (and the alkalies) afterward, residual silica in the form of quartz being practically the last of the abundant rock-materials to solidify. This is the reverse of the laws of dry melts, such as are obtained in smelters; and this difference is due to the fact that the magmas are not dry melts, but contain water and certain elements which under surface conditions are highly volatile, such as chlorine, flourine, and the like; and which, even in the magma, are probably highly mobile. The laws of crystallization in such a mixture are chiefly known to us by inductive reasoning from the phenomena observed by field and microscopic study of the igneous rocks.

The following consideration must be borne in mind in studying all igneous rocks; the common distinction between 'igneous' and 'aqueo-igneous' fusion (made in passing from granites to pegmatites, for example) is certainly wrong. Granite cannot be crystallized from a dry melt; and the transition between granitic rocks and successively more and more basic ones is gentle, showing a gradual change of conditions and the constant though decreasing difference (with increasing basicity) between the igneous rocks and those mixtures that can be obtained by crystallizing dry melts of the same chemical composition. The gradually changing conditions of crystallization that are to be reasoned out for the igneous rocks, from the most basic to the granites and alaskites, do not represent differences in kind, but of degree. They appear to depend upon the fact that water and the other highly mobile elements of the magma are among the constituents which are most difficult of crystallization; hence with progressive consolidation of the magma, more and more of these elements are left over and enter to a larger and larger degree into the composition of the uncrystallized, growingly silicious magmas; and become more and more important in comparison with heat in controlling the fluidity and mobility of these magmas. Yet heat always remains an important factor, both in the rocks commonly recognized as igneous and in the complex series of mineral aggregates (mineral veins) resulting from precipitation from solution in a highly aqueous vehicle, which aggregates I shall presently define as in some sense igneous phenomena; and does not cease to be so till the dissolving water is crystallized at the surface, as ice, an extreme but perfectly logical conception which will readily be apprehended when it is remembered that water is fused (or melted) ice.

The above conceptions involve the idea that a magma is a fluid mixture, restrained from crystallizing into an aggregate of minerals by heat, but which crystallizes out on reduction of heat at a point largely dependent upon the chemical composition of the mixture and especially upon the content of water and certain other highly mobile elements; that in a cooling magma of the composition of what are ordinarily known as igneous rocks the less silicious minerals are first deposited, and the residue becomes more and more silicious, affording on crystallization more and more silicious rocks; and that with this change, and as the temperature diminishes, the residue becomes more and more aqueous, and more highly charged with the other mobile elements.

The crystallization of these successive magmas into minerals or mineral aggregates is represented by a well-known series of rocks from pyroxenites through peridotites, gabbros, diorites, granites, and alaskites: and as at the more basic end I have instanced pyroxenite, a rock composed essentially of a single common rock-making mineral, which is among those first crystallized out of magmas, and which on addition to feldspar becomes, for example, gabbro; so at the other end come certain rocks composed essentially of quartz, the last of the rock-making minerals to be crystallized in abundance out of magmas, and which on addition of feldspar becomes, for example, alaskite. This quartz deposition, as I shall point out, has many stages; but the first period of the pure quartz rock is that where it is still associated with and intercrystallized with small amounts of other rock-making minerals well known as characteristic of the alaskites and the granites, such as alkali feldspar and muscovite. This stage is represented by certain silicious pegmatites and aplites and certain quartz veins or dikes of pegmatitic origin. The fluid which crystallized as quartz in this case, may be called a magma, fully as much as that from which the pyroxenite or the granite crystallized.

In the confusion and uncertainty that has arisen as to whether pegmatites are igneous, aqueous, or aqueo-igneous; whether they are veins or dikes; and

†Else we should have had all magmas entirely differentiated long geological ages ago. The history of rock succession, as observed, for example, in the lavas of the Great Basin, shows that, once differentiation has begun, it may be carried to a close in a relatively short geological period—in a fraction of the Tertiary period, for example.

whether they are intrusive or deposited in place: the stumbling-blocks have been words even more than ideas. I suggest, therefore, that as most if not all igneous rocks owe their composition in some part to water in the magma, and as pegmatites owe their origin and composition to heat as well as water, it would be more correct to consider the whole as aqueo-igneous rocks; or, more accurately, as crystallized-magma rocks; a definition to be taken with that given above for magma. I also suggest that the terms 'dike' and 'vein' as separate terms are misleading, and that the strict limitations of their meaning are the results of misconceptions; and that it might be better to confound the two, or use 'vein' in both senses. While this may shock the conservatism of the average reader, the Germans, exceptionally deep thinkers, have no difficulty in using a single word (*gang*) in this connection; and 'veins' of granite and diorite were often described by the earlier English geologists. It is also undoubtedly true that 'intrusive' igneous rocks may have crystallized entirely in place; and in the accurate sense, I submit that any 'mineral vein' is intrusive, into its country rock.

Most of the commercially valuable metals are numbered among the rarer elements; and these undergo the process of differentiation as well as the commoner elements. They tend to concentrate in the extreme products of magmatic differentiation. A few of the metals of this kind concentrate chiefly or entirely in the extreme basic rock-types: while a much larger number concentrate chiefly or entirely in the siliceous extremes; and some metals split, part going into one extreme and part going into the other. This last circumstance exposes a condition which is probably universal, namely, that the precipitation or solution of a given metal depends largely upon the chemical combination in which it may be with other elements, and not solely on its own properties. Chromium, platinum, and nickel appear to be among the metals segregated into ultrabasic rocks; and it will presently be submitted that the majority of valuable metals such as lead, zinc, gold, silver, tin, etc., go mainly into the ultra-siliceous residue, and in great quantity; while certain metals, notably copper (together with iron) segregate partly into one extreme and partly into the other.

The occurrence of ores of nickel, platinum, chromium, and copper as magmatic segregations in basic rocks like peridotites has been insisted upon by various writers; and also the characteristic occurrence in pegmatites of various valuable minerals, such as tin, molybdenum, and tungsten. I have also insisted, and still insist, that the latter may be characterized as magmatic segregations in the same sense as the former; it is high time to do away with this and other generally ill-understood terms, or use them accurately. I have also described the occurrence of gold in quartz veins so closely allied to pegmatites that they evidently represent only a slight further step in differentiation, and, more rarely, and usually in non-commercial quantity, in pegmatites; and insisted that in such cases the term 'siliceous magmatic differentiation' was the most correct one for the process to which they owe their origin.

To re-state in a different form ideas already explained, it must be understood that after each epoch of crystallization in a rock magma, there remains residual from the crystallized magma rock a more siliceous and aqueous magma, in which the proportion of water to silica becomes progressively greater, since an increasing amount of silica is deposited at successive stages, but very little water at any stage. Finally there results the highly siliceous and aqueous residual magma from which pegmatitic quartz veins have crystallized. With the progressive increase of silica and water, there is a corresponding increase of certain metals, a fact which is exposed by the final precipitation, in the pegmatites and pegmatitic quartz veins, of such rare metals as tin, molybdenum, tungsten, and gold, in considerable quantity (quite out of proportion to their relative amount in the earth's crust).

I now submit further that there results from the consolidation of the pegmatites and the pegmatitic quartz veins, practically all the accumulated water in the magma; that with this water is associated a greatly accumulated (concentrated or magmatically differentiated) quantity of the highly mobile and solvent elements such as fluorine, boron, and chlorine, whose presence in granite and pegmatite magmas is shown by such granitic and pegmatitic minerals as tourmaline, mica, and apatite; that much silica is present; and that there are also present many valuable metals, constituting a large portion (in some instances by far the greater portion) of the whole amount contained in the original body of magma.

I submit that from such a residual magma, quartz veins of later origin than the quartz veins closely allied to pegmatites are deposited, and that in them valuable metallic minerals are deposited; that from these veins a further residue results, still fluid under such conditions, but subject to partial consolidation (or to phrase it differently, precipitation) at a later period, under different conditions, involving chiefly a lowering of temperature; and that many successive stages of precipitation follow, the final stage being when the water has lost most of its heat, and has left behind nearly all of the elements with which it was associated, and to whose mobility and concentration it was so important; and, finding its way to the surface, mingles with the great body of surface and shallow-seated waters which has been so plausibly regarded as the accumulated residue of all crystallized magmas.

The successive stages, according to the theory I present, are marked by differences of earthy minerals, but more delicately, perhaps, by changes in the metallic minerals.

This is the origin of most mineral veins and other forms of ore-deposits, including ores of lead, zinc, copper, silver, gold, bismuth, antimony, arsenic, and other metals.

According to this theory, the metallic hearth, or the factory in which the ores originate, is the zone of differentiation, which is in the lower part of the zone of crystallization. Here the ores which we find

segregated into coarse-textured basic rocks are concentrated, and here also the ores which we find in pegmatites and allied quartz veins; and here are prepared the highly silicious, aqueous, and metalliferous residues from which the majority of ore-deposits are formed.

With the increase in the amount of water comes greater mobility and power of penetration, and the upward tendency of the hot residues results in their passage along openings, especially such as are afforded by fault-fractures, toward the surface. Thus, while pegmatites and pegmatitic quartz veins usually occur in or very close to the earlier consolidated rocks, the successive stages migrate farther and farther away from the metallic hearth (the zone of differentiation); which, in general, means that they are successively deposited nearer and nearer the surface. **Thus the successive stages can be recognized as successive vertical zones of ore-deposition.**

A preliminary attempt, open to much revision, may be made to define some of the principal zones, beginning from the bottom:

1. The pegmatitic zone, containing tin, molybdenum, tungsten, etc., with characteristic gangue minerals, such as tourmaline, topaz, muscovite, beryl.
2. The free gold-auriferous pyrite zone, with coarse quartz gangue.
3. The cupriferous pyrite zone.
4. The galena-blende (galena usually argentiferous) zone.
5. The zone of silver and also much gold, usually associated with metals which combine with them to make substances which are undoubtedly highly mobile, and account for the relatively elevated position of the zone. These associated metals include antimony, bismuth, arsenic, tellurium, and selenium. Characteristic minerals of this zone are tellurides and selenides of silver, gold tellurides, argentiferous tetrahedrite and tennantite, polybasite, stephanite, and argentite.
6. The zone of earthy gangues, barren of valuable metals.

I believe it will be ultimately possible to subdivide these periods. The zone here called No. 5 is believed to be represented, for example, by the middle Tertiary 'bonanza' veins of Nevada and Mexico (these also frequently show the lead-zinc zone and in some cases the copper zone); the lead-zinc zone (No. 4) by the probably early Tertiary ores of Colorado; the copper zone (No. 3) by the late-Cretaceous-early Tertiary ores of the southwestern United States and Mexico; and the gold zone (No. 2) by the immediately post-Jurassic ores of the Sierra Nevada in California. The ores cited as typical in the provinces mentioned show always a decided range, transitional into both upper and lower zones in most cases; and the differing character of the veins of one province from those of another is believed to be to a subordinate degree dependent upon the magma whence they emanated, but principally upon the relative depth exposed by erosion, which, other things being equal, depends upon the age of the deposits.

Within the zones which have been defined, of course, precipitation is not continuous, but is influenced by local conditions; so that there may result in a vertical section of orebodies or zones of deposition separated from one another by barren intervening spaces. Yet in many veins the passage of one zone into a lower one is indicated with increasing depth, such as the change from the silver-gold zone to the lead-zinc zone.

An especially valuable record is afforded along certain fissure-zones that have been repeatedly cemented and re-opened during the mineralization period. Since such a mineralization period is usually of considerable duration, at any given point the ascending waters will grow cooler and cooler, with the downward progress of the cooling of the parent magma, and the consequent sinking of the metallic source; thus the successive zones of mineralization will migrate downward, and successive cementations of successive openings at a single horizon, will show the superposition of one zone upon another originally distinctly lower. Of course, the fidelity of the record depends upon the number of re-openings. Where such re-openings have not taken place, or are not marked, the succession may be recorded in neighboring veins of differing types, which may be parallel or intersecting, and which may represent different zones, deposited at different times.

It is believed, as before stated, that the metal-bearing fluids spring from the zone of differentiation; and the veins deposited by them are usually associated with rocks of intrusive or effusive character, which have been derived from the same source. Frequently the upward passage of such intrusions has broken channels along which the metalliferous fluids subsequently find their way, often on or near the contact, and in many cases within the intrusive rock or in the neighboring intruded rock. Movements attendant upon adjustments of equilibrium following magma migrations bring about repeated faulting and fissuring, along which, in succession, magmas of the common rock-types and metalliferous residues rise. Such fissures or lines of weakness, though filled and cemented, will ordinarily be re-opened at the next strain; thus dikes or volcanic plugs of the ordinary rocks and metalliferous veins often lie side by side, or are superimposed one upon the other.

The close relations between most ore deposits and igneous rocks have been well recognized of late years; but the reason does not appear to be that the ores were leached from the consolidated rocks with which they are associated; nor usually, as has more lately, and with a nearer approach to the truth, been held by the more advanced school, that the ores were deposited by solutions residual from the consolidation of the igneous body with which they are associated; but that, where (as in most cases) the associated rocks do not show differentiation phenomena, both rocks and veins were derived from a common centre. Thus similar veins may be (in different instances) most closely associated with different rocks, and different veins with the same rock; and

the error in supposing a very close connection between rock and vein is a most easy one. At Santa Barbara, in Chihuahua, Mexico, the veins lie in shale, and the only igneous rocks in the immediate vicinity (except later flows of andesitic lava are prominent rhyolitic dikes. From this it might be inferred that the veins were dependent upon the dikes; but actually the latter are distinctly subsequent, and have broken through the former. At Tepezala, in in Aguascalientes, a certain strong and persistent vein (the Peñuela) is everywhere found on one contact, or both, of a rhyolite dike; but examination shows conclusively that the dike is younger than the vein, and has split it. Dikes somewhat older than the vein occur at a little distance; but any tendency to the close connection of the vein and these dikes, inferred from proximity, is avoided by a consideration of the closer proximity of the later dike, with its glassy sanadines. At Idaho Springs, in Colorado, the Stanley vein follows a fissure that had previously been followed by a dike, which it splits or borders; and subsequent to the vein this fissure was followed by a dike of a different rock, which splits or borders the vein. The relation records the succession of magmatic products here introduced; but any tendency to regard the vein as dependent directly upon the earlier dike, on account of the close connection of the two is neutralized by the presence of the subsequent dike, which manifestly could not have been squeezed out of the vein.

Where orebodies occur in, near, or following the contact of igneous rocks, there is evidence, in every case that I have seen (with the exception of certain pegmatite veins and pegmatitic quartz veins), that ore deposition was distinctly subsequent to rock consolidation; and hence that the ore was derived from some deeper horizon. This is true, among other instances, in the case of the copper deposits with lime-silicate gangue, which have been largely produced by replacement of limestone at the contact with siliceous intrusions, and which are frequent in Arizona and Mexico. In every one of the several cases that I have carefully studied, these deposits (which come under zone No. 2 of the above classification) are distinctly younger than the consolidation of the associated intrusive (usually granite or monzonite).

A sub-magma emitted from the zone of differentiation may crystallize with different textures, dependent upon its coming to rest at a considerable depth, at the surface, or in an intermediate zone. In general the coarser texture is evidence of slower crystallization, and therefore, roughly signifies that consolidation has taken place at a greater depth; while the wholly or partially dense, glassy or finely crystalline rocks give evidence of rapid cooling, which signifies that consolidation took place in a relatively cool zone, and hence one near or at the surface. The meaning of such evidence is flexible, for the texture also depends upon the mass of cooling rock.

In general, however, it is probable that the main vertical zones of ore deposition coincide with less distinctly marked vertical zones of rock texture (for a given rock composition), where the veins and igneous rocks have nearly the same period of intrusion. Thus the pegmatitic gold-quartz veins and other pegmatitic ore deposits (zones 1 and 2) are usually associated with medium to coarsely granular pegmatitic and aplitic textures; the principal copper zone (zone 3) usually with medium-granular to coarse porphyritic textures; the principal galena-blende zone (zone 4) with medium-grained porphyritic rocks—the typical 'porphyries' of the older classification; while the gold-silver ores of the superficial class (zone 5) are typically in fine-grained porphyritic rocks which frequently represent surface volcanics.

The explanation advanced above is not offered as a universal one; but it does cover, with a few doubtful exceptions, all the important deposits of metals (except many deposits of the most common metals, such as iron, manganese, etc.) with which I am personally acquainted, and in its different applications it will, I believe, cover the most of the field.

Summing up, this theory proposes that metalliferous fluids, from which most ore deposits are precipitated, are extreme differentiation phases of rock magmas; that most ore deposits and mineral veins, as a class, represent one or the other of the extreme products of magmatic differentiation; and that the most striking chemical differences between ore deposits is due (in the more important class representing the silicious extreme) to successive precipitation in theoretically vertical zones, as the fluid migrates toward the surface, and with diminishing heat, achieves more and more mature crystallization. Secondarily, the differences between ore deposits in different regions depends upon different metallographic magma-provinces.

Tungsten Lamps in Michigan.—The city of Grosse Point, Mich., has recently installed a series tungsten incandescent street lighting system where the advantages of this kind of lighting are well exemplified. The lamps are exceedingly hardy on account of the heavy, short filament. They will burn for nearly 1000 hr. at an efficiency of from one and one-quarter to one and one-half watts per candle-power. Another installation of series tungsten lamps for street lighting has recently been made in Grand Rapids. This has proved highly satisfactory. The extensive use of tungsten in the manufacture of lamp filaments will open a new market for the ores of that metal and tend to steady the price.

Hubnerite in Montana.—The Birdie mine, about four miles east of Butte, is said to have the only commercially important body of hubnerite ore in Montana. It is an old silver mine and is opened by a 1000-ft. adit, a 250-ft. raise, and long drifts and cross-cuts. The hubnerite-bearing orebody is at the west end of the silver-bearing quartz; it is from 12 to 20 in. wide and from 6 to 10-ft. long. The raise follows the ore-shoot to the surface; at the surface the orebody is 3 to 5 ft. wide and about 20 ft. long. About 30 tons of ore that carries 20% tungstic acid were recently on hand in the ore-bin.

SODIUM PEROXIDE IN THE CHEMICAL LABORATORY.

Written for the MINING AND SCIENTIFIC PRESS
By HERBERT W. ROSS and N. M. ZOPH.

Much trouble is experienced in completely decomposing a reverberatory furnace slag by acid treatment alone. This is especially true if the percentage of alumina is large. In order to obtain accurate results a fusion with appropriate reagents is necessary.

The fusion of slag or ore in a nickel crucible with caustic potash and sodium peroxide effects a rapid and complete decomposition. A fusion mixture consisting of four parts of sodium peroxide and one part of caustic potash was found to yield the best results, as it melts more readily than sodium peroxide, and is a more powerful reagent than caustic potash. The two reagents should be mixed thoroughly by grinding together in a mortar. The fusion can be made at a very low temperature, even over an alcohol lamp. A number can be made simultaneously by resting the crucibles on a small plate of ⅛-in. sheet iron and placing the same over the full flame of a Dangler lamp. The cheapness of the crucibles, compared with the cost of platinum, is an important factor and favors the use of this method.

Slag Analysis.—One gram of slag is mixed in a 25 c.c. nickel crucible with 5 gm. of the fusion mixture. The crucible is heated for about 20 minutes at a temperature that will barely cause fusion. After cooling, the melt is placed in a casserole and disintegrated in a minimum amount of water (and it only requires a few moments). The crucible is rinsed off and removed from the casserole, the solution being evaporated to dryness after acidifying with hydrochloric acid. The residual silica is treated with hydrochloric acid and water and collected on a filter. Precipitates are most conveniently burned in small clay crucibles or annealing cups in a muffle.

Iron can be determined directly in the filtrate by the bichromate method. If it is desired to determine alumina, lime, and magnesia, iron and aluminum are precipitated by double ammonia precipitations, calcium and magnesium being determined in the filtrate. Nickel is precipitated with the iron and aluminum, on boiling off the excess of ammonia. By determining the aluminum in the precipitate by the phosphate method and the iron in a separate portion of the slag, the nickel will not interfere with the results. If iron alone is to be determined, a fusion can be made and iron titrated after disintegrating the melt in water, acidifying with hydrochloric acid, and reducing the iron to a ferrous state.

Ore Analysis.—The ordinary analysis of an ore or rock is conducted in the same manner as with the slag, except that a longer period is required for the decomposition.

Copper.—Sulphides and silicates are readily decomposed by fusing with sodium peroxide and caustic potash, leaving a melt completely soluble in acid. Two grams of slag or one of ore are treated in a nickel crucible in the same way as in the slag analysis. The melt is disintegrated with water and acidified with sulphuric acid, an excess of 5 c.c. being added. Practically everything dissolves. A saturated solution of sodium thiosulphate is then added in sufficient quantity to precipitate the copper. The solution is boiled until the precipitated copper sulphide and sulphur collect at the bottom of the beaker, leaving a comparatively clear solution. The precipitate is collected on a filter paper, dried, and burned at a low temperature in a small glazed porcelain crucible. The crucible is placed upright in a beaker containing hot water. Concentrated nitric acid is placed inside the crucible and the water in the beaker is boiled. When the copper has dissolved, the contents of the crucible are washed into the beaker and the crucibles removed. In the case of slags, 10 c.c. ammonia are added and copper determined by the cyanide method. The iodide or electrolyte methods may be employed, if desired, after obtaining the copper in nitric acid solution.

The method has been found to give accurate results. A perfect decomposition of the ore or slag is generally obtained. The assay is much more rapid than the ordinary wet method. No unpleasant fumes are evolved. Only one filtration is required in the process. Altogether this method of copper assay is the most satisfactory one that has been tried by the writers of this article.

Sulphur Determination.—Half a gram of ore is sintered in a nickel crucible with three grams of the fusion mixture. The melt is dissolved in water, acidified with hydrochloric acid, and sulphur precipitated with barium chloride.

Arsenic.—By treating an arsenical ore with the fusion mixture, we have a convenient method of converting the arsenic into arsenic acid, so that it can be precipitated by means of magnesia mixture.

Chromium.—Testing chrome iron or chrome brick with the fusion mixture furnishes the best method for decomposing the insoluble chromates.

These methods, as briefly outlined above, have been in use in the laboratory of the Union Copper Mining Co., at Copperopolis, California, for six months and have proved entirely satisfactory.

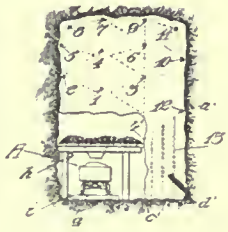
ALABAMA GOLD MINES.—The gold belt enters Alabama from Georgia and terminates in the centre of the State. In the past both placers and quarts veins have been productive, but in recent years activity has been almost confined to the quartz mines. The veins occur in gneisses, schists, and slates; they are in fissures or in bedded and lenticular form. The counties that have produced gold are Chilton, Clay, Cleburne, Coosa, Elmore, Randolph, Talladega, and Tallapoosa; of these, only the last was productive in 1906. The Hog Mountain mine is developed by a 100-ft. shaft and by 350 ft. of drifts. It is equipped with a 40-ton dry-crushing and cyanide plant. The Tallapoosa Mining Co. made a small production in 1905 and 1907, but not in 1906; during that year a 5-stamp mill and cyanide plant were erected. The Dutch Bend mine is equipped with a 20-stamp mill and a cyanide plant; its production in 1906 was small. In Randolph county, at the Pinetuckey mine, there is a 20-stamp mill equipped with Wilfley tables. The mine was developed in 1905 by two vertical shafts, 80 and 125 ft. deep, one incline shaft, and about 600 ft. of tunnels. In Cleburne county, at the Mossback and Lucky Joe mines of the Turkey Heaven district there are 10-stamp mills and at the Gold Hill mine there is a steam 2-stamp mill. A dredge was operating at Clear Creek in 1906 and there were placers at Arabacooche and Chulafinney. The Idaho mine in Clay county has not been operated for some years. The precious-metal production of the State in 1906 was 1205.51 fine ounces of gold, valued at $24,921, and 124 fine ounces of silver, valued at $83.

THE ORE from the mine of the Dominion Antimony Co. at West Gore, Nova Scotia, contains auriferous stibnite in a quartz gangue. In making concentration tests on this ore, wet crushing was found to cause too great a loss from slime carried away in the water. Dry graded crushing, and careful sizing to 24 or 30 mesh, followed by wet concentration, seemed to give better results. In one test 6¼ tons were crushed with rolls to 24 mesh and treated on a Wilfley table; this yielded concentrate, middling which was returned to the table, sand tailing to be leached for gold, and slime. There was a saving of 90% of the antimony.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

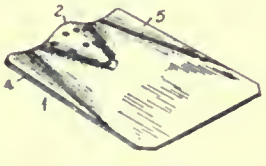
METHOD OF TUNNELING IN ROCK.—No. 877,779; Joseph P. Keane, Wallace, Idaho.



The method of tunneling which comprehends the shooting of the cut substantially simultaneously partially with tape and partially with electric fuse. The method of tunneling which comprehends running a heading along the bottom or track level and along one permanent side of the tunnel, building a staging with sufficient clearance underneath for the passage of the ore-cars, provided this staging with suitable openings over the line of travel of the ore-cars and then casting down the material on to the staging to the roof-line.

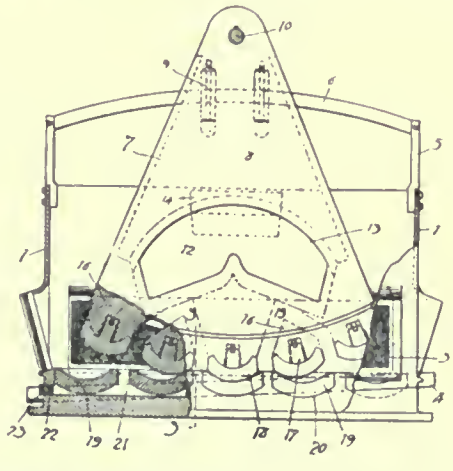
MINER'S SHOVEL.—No. 877,574; David B. Lewis, Bisbee, Arizona.

A square shovel blade composed of a single thin sheet



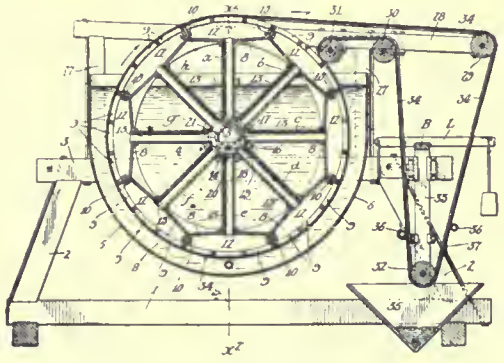
of metal having its front portion flat and straight across its entire width with the sides thereof curved upwardly at the rear end of the blade and bent outwardly and downwardly toward the front, merging into said flat front portion near the middle of the blade and with their inner faces lying in approximately a horizontal plane, said sheet having its rear end bent upwardly from a point beyond the middle, whereby a central depression is formed to receive the material to be lifted.

STAMPING AND GRINDING MILL.—No. 877,615; Thomas M. Topp, Richmond, California.



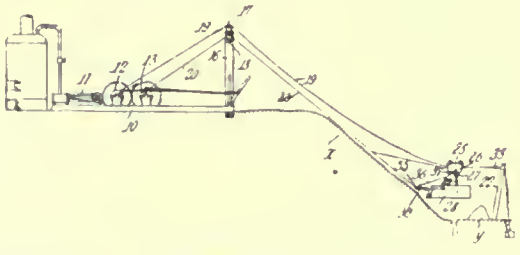
A stamping and grinding mill comprising a mortar, a row of concave dies therein, a pestle having a corresponding row of convex shoes at its lower end, and means for imparting a rocking motion to said pestle in the plane of said row, the mortar and pestle being provided with devices arranged to engage each other to maintain the pestle in an upright position while so rocking, one of said devices being capable of rotary motion, for the purpose of reducing friction, substantially as described.

SLIMES-FILTER APPARATUS.—No. 877,631; Edwin M. Clark, Los Angeles, Cal., assignor to Edwin M. Clark Slime Filter Company, Los Angeles, Cal., a Corporation of South Dakota.



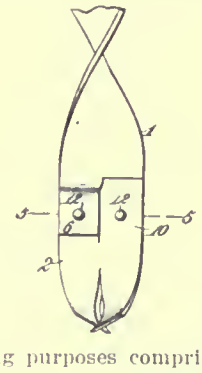
In a slimes filter apparatus, a wheel having a perforated rim with grooves near each edge of the rim, a pervious belt traveling over said wheel, a belt having welts in each edge which closely fit the said grooves and prevent leakage between the edge of the belt and wheel, the rim of the wheel being formed in hollow sections, a tank containing the liquid to be filtered in which the wheel is immersed, means for applying suction to hollow sections of the rim to draw the liquids through the pervious belt into the hollow sections and cause the solids to adhere to the belt, and means for limiting the suctions to sections which are fully immersed in the liquid or covered by the belt.

EXCAVATING-MACHINE.—No. 877,578; Milton S. Longnaker, Pleasant Hill, Ohio.



In apparatus of the class described, an inclined cable or support, means for slackening and drawing the cable taut to alter its degree of inclination, a movable carriage arranged to travel on the inclined cable and movable thereon in one direction by gravity, and an operating cable connected to said load carrier and arranged to haul the same in the opposite direction.

DRILL.—No. 877,892; Aaron E. Jennings and James W. Jennings, Central City, Ky., assignors of one-third to Gregory Jennings, Lima, Ohio.



A drill for mining purposes comprising a shank section and a bit section, said shank section having its lower portion formed with a pair of tongues offset with respect to each other, said bit section having its upper portion offset to form shoulders and further having a notch in the top edge thereof, said upper portion of said bit section adapted to be positioned between and overlapped by the tongues of the shank section, and said tongues bearing against the shoulders of the bit section and means for securing the shank section to the bit section.

GOLD PRODUCTION AND ITS EFFECT.

By F. Lynwood Garrison.

*The world's gold production has not reached an abnormal or unhealthy proportion when compared with the enormously increased commercial activities of the times. On the contrary, if anything, we need more gold, for business seems to have outgrown the supply of circulating medium, that is, coined money or currency. Gold is certainly not cheaper, and as some of the chief present sources of supply are exhibiting indubitable signs of exhaustion, it is not likely to become so. It is therefore evident that if the present rate of increase is to be maintained we must soon call upon the comparatively undeveloped fields of Siberia, Central and South America, and perhaps parts of Africa.

Continuing this analysis further, we find it is evident that the quantity of gold derived from copper ores must be quite large. In the statistics for Arizona and California, this particular phrase of the yield seems to be given only in terms of silver, that is, the amount of gold thus derived is not specifically stated. In Montana, however, $1,434,935 of the total $4,889,233 of gold produced by that State in 1905 came from the copper ores; that is, about 29% of the gold yield of the State was thus obtained, and in 1906 it was probably much larger. New Mexico, for 1905, gave $76,455, or about 29%, from copper ores, while in Oregon it was only 1½%. Within the old gold-producing States it seems we shall in the future have to look to the dredging industry and the copper ores for the increase of gold production, if, in fact, we are not obliged to depend upon these sources to maintain the present amount and prevent a steady decline. The total yield of gold as an incident of the copper industry is evidently an important element, although the precious metals thus derived are proportionately very small and may be regarded as a by-product, since copper ores do not usually contain more than one or two dollars of gold and silver per ton, the ratio being about one part of gold to three or four of silver. The yield of these metals from this source will therefore depend upon the production of copper, which in turn is regulated by the price of that metal.

From a careful consideration of the whole subject, it is evident that the gold production of the United States (not including Alaska) is not likely to continue exhibiting a substantial increase, if it can maintain its present rate. There are doubtless many gold deposits of one kind or another in the United States that could be made to pay enormously in a country like China, where there is an abundance of cheap, and for the purpose, efficient labor, but in this country of high prices and extravagant living, such deposits would probably not yield a new dollar for an old one, even with the best of our so-called and sometimes over-rated labor-saving appliances. I believe it is an error to suppose modern mining and metallurgical methods can or will materially modify the gold production of the United States, although of course in some, and perhaps quite a number of instances, the yield of gold can in this way be increased, but as a factor of the whole question these modern innovations may be said to be comparatively unimportant.

Gold is not, as commonly supposed, a rare metal, indeed it is quite a common one in the crust of the earth, but it is exceedingly widely distributed and finely disseminated. It probably occurs in appreciable, though minute quantities throughout many, if not most of the Tertiary eruptive rocks that compose the vast chain of mountains extending from Alaska on the north to Tierra del Fuego on the south. The gravels underlying Philadelphia contain it, and the iridescent though dishonest scheme of Jernegan was based upon the substantial fact that gold does occur in sea water. The forces of Nature through millions of years have concentrated some of this gold in certain places favorable to its accumulation. By common process of erosion the particles of gold gather in stream-beds, sea-beaches and other alluvial and fluvial deposits. Through its solution in the circulating "waters under the earth" gold is carried from place to place in the rocks and precipitated in favorable spots, usually along with other metals. The phenomena involved are very obscure, but are slowly yielding to scientific study and research. In general, it may be said that the processes of metallic accumulation within the rocks are essentially superficial in the sense that they are probably going on at no great distance below the surface. Metallic veins and deposits do not usually increase in size or richness with great depth, although there are of course some mines that can be worked about as far below the surface as our present mechanical limitations will admit.

*Abstracted from the proceedings of the Franklin Institute, Philadelphia.

Distances.—From New York to San Francisco the distance shown by rail across the continent is 3191 miles; via Tehauntepec, 4415 miles; via Panama, 5305 miles; via Punta Arenas, 13,089 miles, and via Suez and Singapore, 17,672 miles. From New York to Nome, Alaska, the distance via Port Townsend is 5555 miles; via San Francisco, 5896 miles; via Tehauntepec, 7130 miles; via Panama, 8010 miles, and via Magellan Straits, 15,840 miles. The length of route from Vladivostok, Asiatic Russia, to New Orleans via Magellan Straits, is 17,445 miles, while the distance from Vladivostok to New Orleans via San Francisco and thence by rail is but 7188 miles. The distance around the world via the Trans-Siberian and our own transcontinental railway lines is shown to be 17,997 miles, being: from New York to St. Petersburg, 4632 miles; from St. Petersburg to Vladivostok, 5809 miles; from Vladivostok to Port Townsend, 4357 miles, and from Port Townsend to New York, 3199 miles. The sailing distance around the world from New York via Suez, Singapore, Manila, Guam, the Hawaian Islands, and Panama Canal to New York again would be 23,092 miles, being in detail: from New York to Singapore, 10,170 miles; thence to Manila, 1386 miles; thence to Guam, 1506 miles; thence to Hawaii, 3337 miles; thence to Panama, 4665, and thence to New York, 2028 miles.

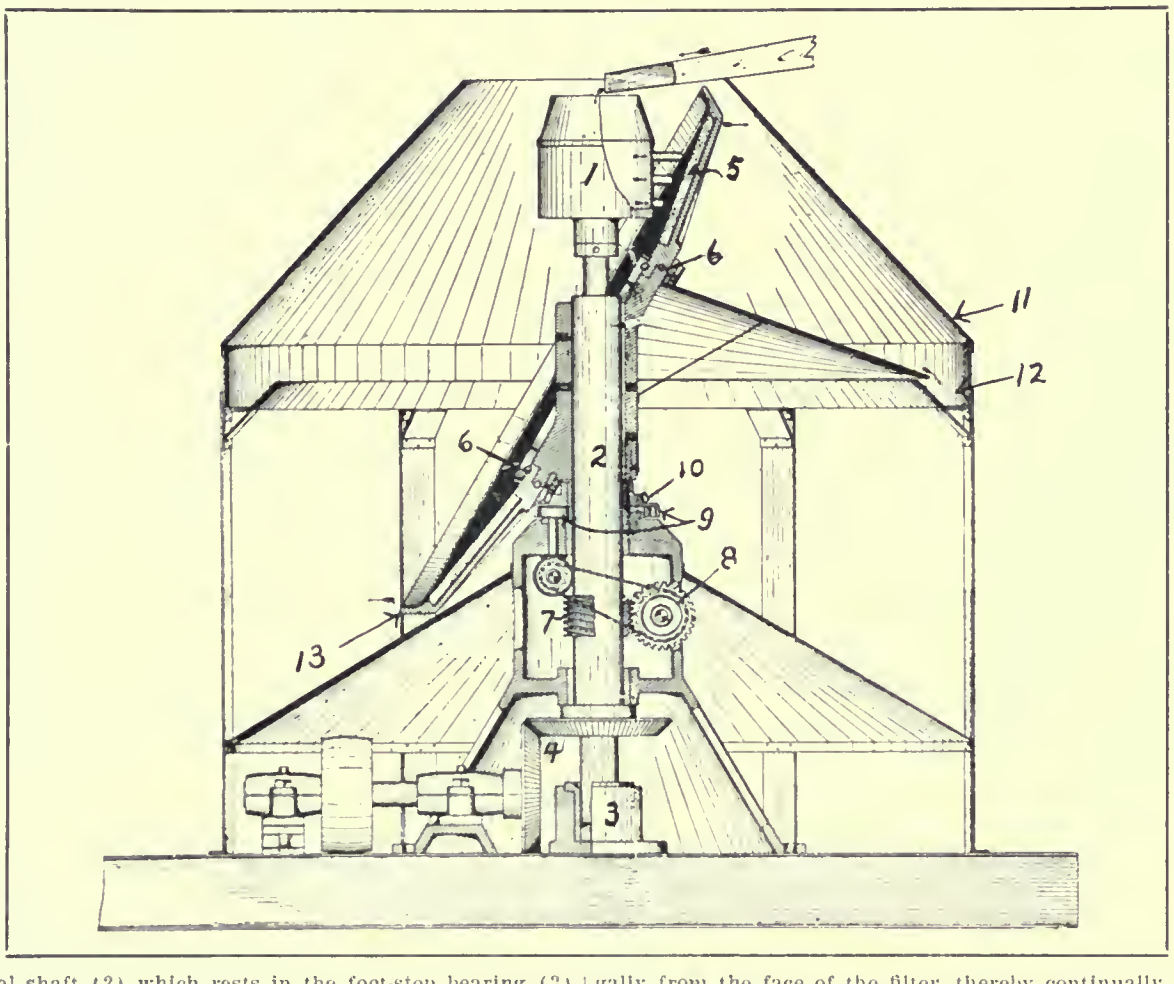
A New Continuous Filtering and Straining Machine.

The continuous filtering and straining machine of L. C. Trent is a new candidate for favor among engineers interested in filtering and straining. It is intended to separate finely divided material, of any description, from liquids, and is claimed to be the missing link required to form a continuous cyanide process. The inventor claims it will separate a stream of pulp from a stamp-battery or any other stream of liquids carrying solids, into a continuous flow of clear liquids on the one side and a stream of comparatively dry solids, on the other. The design is so ingenious and novel that it is worthy of close study, on account of the numerous closely woven forces set in motion and employed in its operation.

The machine consists of a receiving hopper, marked (1) on the accompanying drawing, and revolving with the vertical shaft (2) which rests in the foot-step bearing (3) and is driven by the bevel gear (4). The revolving dish-shaped filter-mat (5) is attached to, and is carried around by, the vertical shaft (2) at a speed of from 200 to 600 rev. per min., generating the centrifugal force and wind-pressure for filtering and discharging. This filter-mat (5) at the same time revolves on its own axis at 30 rev. per min. and is carried by the ball-bearings (6). The power for revolving the filter-mat (5) is transmitted by the worm-gear (7) through the sprocket and chain-drive (8) and annular gear (9) and bevel gear (10), thus forming a ready means of altering the relative speeds of revolution of filter-mat to vertical shaft.

After the correct relative speed has been determined for any constant class of material, a simpler drive can be used for this purpose. Also, if desired, a top drive with quarter-turn belt can be used for the vertical shaft (2) in place of the bevel gear (4) here shown. The upper portion of the machine is enclosed by the housing (11) and surrounded by the launder (12), which collects the filtered solution. The solid material is discharged at (13) and may be collected in a hopper under, or at the side of, the machine, from which it can be removed by a conveyor-belt, sluicing, or other means.

In operation, this revolving-disc filter has a first or primary motion, wherein the inclined disc revolves rapidly in a horizontal direction with the spindle (vertical axis), which produces a centrifugal pressure against the face of the upper half of the filter which does the filtering. The same force takes place in an opposite direction from the surface of the lower half of the filter, which discharges the filtered solids at the same time the disc-filter revolves on the axis of its plane, which is the secondary or distributing motion. The first motion described creates a strong centrifugal pressure on the upper face of the filter against which the material to be filtered is discharged from a small reservoir revolving with the machine, and the strong centrifugal action instantly strains the liquid from the solids, the latter remaining on the face of the disc-filter to be carried by the revolving or secondary distributing motion to the lower portion of the filter, to a point where it is ejected centrifugally from the face of the filter, thereby continually cleaning the filter face, which returns with a clean surface for a fresh charge. Thus the machine, when in operation, is constantly feeding and as constantly discharging.



The centrifugal force is not only active at the top, tangentially to the main spindle of the machine, but with the filter-disc dished, it is equally strong tangentially from the horizontal radii of the filter-disc, as the action is then oblique and has even greater force in filtering; the wind-pressure and adhesive force together, with a partial vacuum created by the centrifugal force, act on the moisture absorbed by the mat, holding the solids in place. The material, striking a clean surface, is instantly deprived of most of its liquid contents and the solids are carried to the lower half of the filter, where they are discharged by the same force that filters them, and the filter is cleaned for continued action.

By this method, the cake is always thin on the filter-faces, consequently, easily filtered, a clean filter-surface is continually provided, thus avoiding any necessity for the high pressures required in filter-presses and ordinary centrifugal machines. The action of the machine is continuous, both in feeding and discharging, and the discharged material is finished as far as mechanical methods of remov-

ing moistures can be employed, the degree of dryness being regulated by the speed of the primary motion that regulates the straining or filtering pressure, and the speed of the secondary motion, which regulates the time of exposure of such action.

In a machine with a 4-ft. diam. of filter-disc, the available filter-area will be 8 sq. ft., and if the vertical axis of this machine is revolved at 400 rev. per min., and the disc revolves on the axis of its plane at 30 rev. per min., and a cake of slime ⅛-in. thick be collected, it will have a capacity of 140 tons of dry ore per 24 hours and will require less than 20 hp., and no labor or attendance further than an occasional oiling and looking over.

This machine is patented in the United States and principal foreign countries, and is the invention of L. C. Trent, of the L. C. Trent Continuous Filter Co., of Reno, Nevada, who is now perfecting the machine for the market.

Books Reviewed.

The public that reads technical literature is often imposed upon by having to digest half-baked productions likely to cause mental dyspepsia. During recent years we have seen nothing quite so bad as 'The Falls of Niagara' by Joseph William Winthrop Spencer, M.A., Ph.D., F.G.S., published by the Geological Survey of Canada. We marvel that such a volume of cool egoism, muddy thinking, and wretched writing should have been issued from the office at Ottawa, for we believed that the regular editor of the Canadian Survey was a mining engineer of some repute, possessed of an excellent literary style, and the necessary good taste in matters of this kind. The book is well printed and beautifully illustrated; in fact, the manner of it is disproportionate to the matter. As a warning and example of bad writing we quote seven paragraphs.

"The history of Niagara river is only the expression of that of the lake region in all its complicated parts. The investigation of one feature imperceptibly leads us afield until we pass the boundaries of our original topic; thus it is here. But the new observations react and more fully explain the phenomena."

"In a general way the recession of the falls depends upon three factors—their height, their volume, and the character of the rock formations, which are being channelled by the stream. The falls have retreated across a very level country, underlaid by almost horizontal rock formations having a great degree of uniformity, as was noted even so long ago as 1789."

"Few people have supposed that the recession was not uniform; fewer still would think that the story had not all been told concerning a commonly known natural feature. The history had been partly anticipated in the discovery that the volume and descent of the water have not always been the same, and that some of the features have changed to a degree."

"The old floor of the Park is so nearly 180 feet above the river in the channel below, or 280 feet above Lake Ontario, that this height may be taken as effective in the excavation of the gorge with the river at present level, thus making allowance for its increased velocity."

"The thickness of the underlying shales is constant. As I have found the character of the falls during the middle portion of this long stage, these corrections will approximately cover the case, although their precise amounts are not determined more closely. I do not believe that the apparent error will ever be found to reach ten per cent, with the rainfall during the recession being approximately the same as at present."

"The age of the Falls of Niagara, which are post-glacial, is one of the great questions of geology having a world wide interest. The complexity of their history, which meets one on investigation, disappears in applying precise methods and carrying them sufficiently far. It was principally due to a failure in understanding the nature of the differential uplift of the land, and tilting of the water-basins, so as to change the height of the falls and their volume; and to previous failure in making the determination of the work of the falls at the different stages in their history."

"There need be no suspicion that underlying hypotheses have been developed, as I had none to uphold, except what might come from the facts inductively. The problem has been a long one to solve, so that no one who has not at least examined the investigations is entitled to call in question the features of the falls, gorge, etc., as to their furnishing evidence in bringing us near the age of Niagara, even though he may be bewildered by the great mass of facts brought out by methods that had to be specially developed for this solitary problem."

This is the delirious trimmings of scientific literature; as you read it you wonder if you have lost your senses, you suspect the Welsh rabbit (not rare bit) of last night and you vow to stick to mineral water in future. Yet we would be disinclined to be so severe, if the author had not put himself on a pedestal. According to him, all previous writers on Niagara were fools, although we remember a modest pamphlet by G. K. Gilbert, who managed in 29 pages to give more facts, and to illuminate them better, than Dr. Spencer in his 490 pages. Surely the Geological Survey of Canada can use its funds to better purpose than to issue scientific balderdash sumptuously printed. One purpose the book can fulfill: It illustrates every kind of error in arrangement of evidence, in sequence of thought, in construction of sentences. If you want to write an essay on a scientific subject, you can at least learn what to avoid by reading 'The Falls of Niagara.'

'Steam-Turbines,' by Carl C. Thomas, Professor of Marine Engineering, Sibley College, Cornell University. Third edition, revised and enlarged, 1907; John Wiley & Sons, New York; 8vo xiii and 334 pp., 145 fig., 20 pl.; cloth, price $4. This book has been written primarily for students and other persons possessing a fair knowledge of mathematics who may desire to equip themselves for taking up steam-turbine work. Special attention may be called to the new problems in the design of the Curtis and the Parsons types of turbines, to the suggestions regarding turbine analysis, and to the 'Diagram of Heat-contents of Steam,' the superheated region of which is plotted from the results of the author's recent investigation of the specific heat of superheated steam. This edition also contains new material relating to the application of steam-turbines to marine propulsion, including illustrations of some of the most recent turbine steamers. For sale by the MINING AND SCIENTIFIC PRESS.

Catalogues Received.

CHALMERS & WILLIAMS of Chicago, Ill., have issued a substantial cloth binder containing their 'Catalogue No. 1,' second edition. This catalogue is in sections as follows: Section A, rock breakers; Section B, stamp batteries and accessories; Section C, gold and silver milling machinery; Section D, Huntington mills and crusher rolls; Section E, Frue vanner; Section F, concentrating machinery; Section G, the New Blanton patent self-tightening cam; Section H, hoisting cages and landing dogs; Section K, Chile mills; Section L, Kennedy gyratory crusher.

THE AETNA POWDER CO. of Chicago, Ill., has issued a catalogue entitled 'Aetna Dynamite'; besides describing the company's manufactures, it contains much useful information about loading and firing blasts and about blasting under water, blasting ice, shooting wells, and blasting stumps.

THE SCHUTTE & KOERTING CO. of Philadelphia, Pa., has sent us its 'Catalog 4, Section Q, which describes and illustrates its water-jet primers.

THE LIMA LOCOMOTIVE & MACHINE CO. of Lima, Ohio, has issued a nicely illustrated catalogue describing the Shay geared and rod locomotives

THE SULLIVAN MACHINERY CO. announces that George M. Bertram, for several years connected with this company, is appointed local manager of its Joplin, Missouri, branch office, succeeding Randolph D. Talmage.

Editorial.

FURTHER NEWS from Rawhide will be found under 'Special Correspondence.' It is evident that the stampede is attracting the adventurous from all over the West, and we hope that the real work of mining will be undertaken vigorously.

TECHNICAL WRITING forms the subject of an interesting letter sent to us from the wilds of Sinaloa by Mr. A. W. Warwick. His communication contains a lot of good sense and useful advice. It is said that "you cannot teach an old dog new tricks," and it may be that the seniors of the profession will be more annoyed than aided by advice in such matters, but we are glad to help the youngsters. The future is to them and to the MINING AND SCIENTIFIC PRESS.

TUBE-MILL LININGS have come to the front lately, both by reason of the increased usefulness of the tube-mill as a machine for re-grinding and because of a little friendly controversy in regard to the origin of a certain improvement in which flinty pieces of ore are held in cement so as to serve as an agent of abrasion. Mr. J. R. Brown's letter gives courteous expression to his claims as an inventor and it is likely to be well received by his fellow practitioners.

JOPLIN is the greatest lead-producing region in America, therefore an article describing the occurrence of the ore is sure to be interesting, but the contribution of Mr. F. Lynwood Garrison has further claims to attention, as being a scholarly essay prepared by a mining engineer who is also a geologist. The discussion of the origin of the ore and the comparison between the various theories suggested by scientific men, should prove instructive and suggestive to those engaged in the exploration and exploitation of lead deposits elsewhere.

CHINA is not a popular region among mining operators, but to such as are interested in that awakening country the regulations recently issued by the Imperial Government will be important. The regulations afford valuable evidence of the present feeling of Chinese officials toward foreign capital, and of the way in which mining operations are likely to be hampered. It is not considered at all likely that the signatory Powers will agree to the regulations in their present form; in all probability a new set will have to be drafted and the whole matter will remain in suspense for some time to come. The rate of progress now observable reminds one of a variable approaching its limit—it never actually gets there. On the other hand, if we take a more

cheerful view and suppose that the idea of a provincial mining bureau can be carried out adequately, there should be a stimulus to mining. In Sze-chuan a good start has been made as regards the bureau in that province, and Mr. Lo Su Chi, who graduated from the University of California last year, has been appointed to the post of Provincial Geologist, and even more recently he has been sent into Manchuria to co-operate with the Japanese in the survey for a railroad. When the railroad gets into Sze-chuan there should be a noteworthy development of its mineral resources. With the exception of coal, and the solitary Shantung gold mine, the provinces of Sze-chuan and Yunnan appear to be the only promising regions open to foreign exploitation. A good deal is said about alluvial gold in Manchuria, but such general talk is not based on any precise information. There are numerous quartz veins in that country, but they are small. The working of the placer ground by expert panners, who expect to earn only 10 to 15 cents per diem, does not seem to offer much of an opportunity to modern machinery. There may be undiscovered Yubas and Tonopahs in China, but the best informed travelers do not favor any such joyous anticipations.

Revival in Gold Mining.

WHETHER RAWHIDE is another Goldfield or Cripple Creek remains to be proved, but we welcome the interest the discovery has evoked as evidence of speculative activity in gold mining, in Nevada in particular and in the West in general. Undoubtedly when banks fail, railroad shares shrivel, the price of copper collapses, and other such suggestions of instability are thrown at the intelligence of capitalists, whether large or small as regards the amount of money at their disposal, there is a tendency to turn to the industry least affected by drooping markets and timid manufacturers. That favored industry is gold mining. But by the industry of gold mining we do not mean the pestiferous activities of industrious schemers devoid of honesty and with such a sacred regard for truth—as not to use it. Our daily contemporary in San Francisco, *The Chronicle*, for example, prints two columns of balderdash concerning Rawhide couched in language calculated to discount any belief in the serious character of the mining operations that have been started there and full of weird statements such as would drive any well informed man to conclude that Rawhide was the particular rendezvous of wildcats. Such flapdoodle as *The Chronicle* prints will not help Rawhide nor Nevada, nor any form of legitimate mining. We read that "mining engineers give it as their opinion that these are true fissure veins, which means permanency and great depth." We are told further that "geologists are of the unanimous opinion that the formation of Rawhide indicates great depth to the orebodies, with increasing values showing with depth." This sort of twaddle is as old as the hills: in the days of Rameses they peddled shares by the aid of just such fables. Every intelligent man knows that such statements are the stock in trade of feline financiers, they are worthy of the steam-heated imagination of an aberrant reporter making copy for an irresponsible and disreputable newspaper. Again, we are told that the ore struck on one of these claims assays $920.90 per ton. Note the cents. As a matter of fact it is safe to say that there is not one ton of such stuff available, although there may be plenty of good ore, and what is meant is that a specimen assayed 46 cents per pound, or 3 cents per ounce, which is at the rate of $920 per ton, if there were a ton of it. This method of taking selected specimens and speaking of them as averages is extremely misleading to the public, and it is a method that plays into the hands of the unmistakably dishonest promoters of enterprises having as little to do with real mining as the thimble-rigger at the races has to do with the breeding of fine horses. By all means, let us have a revival of activity in gold mining—and if in Nevada, so much the better—but cannot we be spared the revival of the spoofery and malpractice that have ever been an incubus upon honest industry. Money is scarce, why waste it on air-ships; there is plenty of opportunity for applying it beneficently to the solid ground of ascertainable fact.

Biographical Note.

ONCE EACH YEAR the Bulletin of the American Institute of Mining Engineers contains a biographical summary of the members deceased during the preceding twelve months. We referred to this necrology last year and we shall do so again on this occasion, since it is sobering, even uplifting, to give a few moments to recalling the honored dead who have dropped out of the ranks of our profession, leaving a memory, an example, or a warning. The year 1907 saw the end of many useful careers; we mention John Blue, of Quebec; W. R. Boggs, Jr., who met a tragic death in Mexico, being stoned by a mob of workmen clamoring for their wages; E. E. Burlingame, the veteran assayer of Denver; George H. Evans, a hydraulic mining engineer, remembered in New Zealand, Colorado, and California; William Glenn, of Baltimore,, who contributed several valuable papers to the Institute; Frank H. Hearne, the president of the Colorado Fuel & Iron Company; George C. Hewett, of Colorado Springs, a worthy engineer; Thomas E. Johns, a Cornishman who made a record in South Africa; W. J. Johnston, the energetic publisher, one of the pioneers of technical journalism; Clermont Livingstone, the general manager of the Tyee Copper Company; Charles A. Molson, at the height of his reputation as a mining engineer, one of the leaders of the profession in America, who was killed through an accident while shooting ducks; Louis Pelatan, a clever Frenchman whose name is given to a variation of the cyanide process, he died from injuries due to a railroad accident; Alfred M. Rock, formerly on the Geological Survey, who forfeited his life in a courageous effort to do his duty in a mine fire; George W. Rose, a chemist and cyanide superintendent, who was killed in defending his wife against two Mexican burglars; G.

C. Simpson, a Scotch chemist who became an assayer and ore-buyer in Mexico; E. B. Willard, one of the ironmasters of Ohio, who was killed by the explosion of a blast-furnace; John A. Walker, of the Dixon Crucible Company, a veteran Scot of the best type, an honorable business man and a good citizen. In the Bulletin will be found paragraphs outlining the career and work of these men, who in 1907 crossed the range that guards the farthest horizon of life. Dr. Raymond prepared many of the biographical notices and they have that message to the living which is the best feature of a record of the dead. The veteran Secretary says that the list for 1907 is "peculiarly sad, comprising, as it does, so many sudden deaths by violence or accident, so many veterans, removed too soon, and so many young men whose early departure impoverishes the future even more than the present." After a few reflections, he says that if he may be permitted to preach at all he would like to enforce "the duty of every one of us, old or young, to give to his brethren, as he goes along—and without waiting for some future occasion for a comprehensive and monumental contribution to technical literature—the results of his observation and experience." Let this be the lesson left to us by the friends whom we have lost. Regrettable indeed is the loss of knowledge, of facts and experience, that is entailed by the silent men who pass out of life leaving no message. It may be that there are some who write too much, but for two who write more than they know there are 98 who fail to transmit the little knowledge they have gained. Man's chief ground for superiority over the dumb brute is his ability to hand down the record of his thought and work to the descendants whom he never will see; the greatest loss in the world is the waste of experience.

Metal Markets.

WE LEARN from New York that a more hopeful feeling exists and that confidence has steadily increased since the first days of the year. Consumers who in the last quarter of 1907 had taken only the metal they were absolutely compelled to purchase, either by contract or to replenish their depleted stocks, have shown more interest in the market. While prices did not appreciate at once to any noteworthy degree, there was evidence that not only had the downward movement in prices been arrested, but it was found in a number of instances that the depreciation had been carried too far. That is why, despite a greatly reduced consumption, prices advanced. This cheerful movement continued until the last days of January, when the failure of several banking institutions again reminded the public that there were many weak spots in the financial fabric. In addition, the political outlook became overcast and the last message of the President to the Congress angered the leaders of finance and tended to cause further disquiet. Since then the metal markets have drifted; there has been a feeling of uncertainty and a disinclination to operate, until the end of February has seen a state of suspense wholly inimical to trade.

As regards copper, the domestic consumers so far this year have operated in a very moderate way; the electrical industry unquestionably is poorly supplied with orders and new business is scarce. As regards present consumption, it is probable that only about 40 per cent of last year's consumption will be absorbed this year. In some other branches, as in building construction, the orders are more plentiful, but, in a general way, it is safe to say that consumption in this country is only one half of what it used to be during the recent period of prosperity. Europe has been a large buyer for the last three months, with the exception of the past fortnight, when orders stopped. During the past ten days both the Calumet & Hecla and the United Metals Selling Company, who were notably inactive, have become anxious to make sales, and large orders were taken by them in Europe at a great concession in price, namely, at 12⅝ to 12¾ f.o.b. New York. They continue to offer at these figures, so that the market is likely to recede further; but at these very low prices it is most probable that a large buying movement will be set in motion.

In spite of the large decrease in production, the accumulation of lead at the refineries does not show any perceptible diminution. This also is due in part to the enormous decrease in demand for electrical purposes, for the white-lead consumption is fairly satisfactory. On the other hand, for general building purposes, the demand ought to be better. There are sellers at anything over 3¾ cents, delivered at New York.

In spelter a very large stock has accumulated; our information indicates that between 35,000 and 40,000 tons is being held. Galvanizing has been very poor indeed, although the market has improved just lately and is likely to improve still more. Nevertheless, the largest galvanizers have not taken delivery of the metal contracted in November, December, and January. This fact seriously inconveniences the smelters. If, in spite of this, prices have hardened of late, it is due simply to the low price previously reached, for spelter cannot be purchased below 5 to 5¼ cents. Supplies of ore outside of Joplin have been practically nil, and most of the smelters had either to close down entirely or reduce their output considerably. Of late, sales have been made at 4.70 to 4.80 f.o.b St. Louis, against the lowest price of 3.90 to 4 cents early in December, but even at this figure spelter cannot be produced profitably and the smelters are compelled to purchase ores on a considerably higher basis than they can realize, and they have to do this in order to keep at least a part of their works in operation.

Thus, on the whole, the immediate outlook is far from cheerful, but it is confidently believed that the general financial condition will continue to improve and this will enable the railroads and other large industrial corporations to get money, which in turn will stimulate orders for the metals. No rapid change in the metal market is to be expected, but it seems safe to assert that the worst is behind, not in front, of us.

Personal.

S. F. EMMONS is at New York.

FRANK H. PROBERT is at Globe, Arizona.

LOUIS WEBB has returned to Cambridge, Mass.

CLAUDE VAUTIN is in the northern part of Chile.

E. L. BLOSSOM, of Butte, is here for a couple of weeks.

W. E. DEFTY is now in the Bradshaw mountains, Arizona.

F. H. MORLEY of Denver is on a business trip to Chicago.

R. K. HUMPHREY has returned to Denver from Arizona.

J. MORGAN CLEMENTS has returned to New York from Mexico.

W. L. COBB has returned to San Francisco from Gold Hill, Nevada.

ETIENNE A. RITTER, of Colorado Springs, is at Goldfield, Nevada.

W. H. SHOCKLEY was married in San Francisco on January 20.

W. R. RUST, manager of the Tacoma smelter, is returning from a holiday in Europe.

O. H. PACKER has moved back to his old quarters in the Mills Bdg., San Francisco.

C. BARING HORWOOD is returning to Johannesburg, after a short holiday in England.

GEORGE A. CARTER sailed from Vancouver for Wellington, New Zealand, on February 25.

FRED W. DANIEL, of Denver, recently with the Vidler Tunnel Co., is in San Francisco.

J. M. BOUTWELL has returned to Washington, having finished his geological work at Cananea.

R. H. BURROWS has returned to Guanajuato, having completed several inspections in Chihuahua.

W. A. HENDRYX, of Denver, has returned there from a visit to Salt Lake City and San Francisco.

N. S. KELSEY has left San Francisco to examine an oil discovery in San Luis Obispo county, California.

HAROLD TURRELL and PHILIP F. PATTERSON have an office, as mining engineers, at Penhalonga, in Rhodesia.

J. H. MACKENZIE, general manager for the Goldfield Con. Mines Co., is on a visit to San Francisco for a few days.

JESSE J. MACDONALD is on a visit to New York, where his address is with the American Trading Co., at 25 Broad Street.

FRANK OLDFIELD has returned to Los Angeles, having visited Rawhide and several other new mining districts in Nevada.

R. GILMAN BROWN is in Chile. His address is care of F. Lumley, Casilla 18D, Santiago. He will be there until the middle of April.

A. C. BEATTY has been selected by a committee of stockholders of the Montgomery-Shoshone Mining Co. to examine their mine at Rhyolite, Nevada.

JOHN HAYS HAMMOND is recovering most satisfactorily from the operation he recently underwent for appendicitis. He is at the Fairmont hotel, San Francisco.

LAFAYETTE HANCHETT has returned to Salt Lake from a visit to London, where he attended the annual meeting of the Boston Con. Mining Co., for which he is manager at Bingham.

JOS. B. TOMLINSON, of the firm of Tomlinson & Norton, consulting mining and civil engineers, of El Paso, Texas, is reporting on a gold-copper property for the Utah Mining Co. The property is 100 miles southwest of Casas Grandes, on the Aros river, in the State of Chihuahua, Mexico.

GARDNER F. WILLIAMS, ex-manager of the De Beers Con. Diamond Mines in South Africa, and formerly a resident of California, and now of Washington, D. C., arrived in San Francisco on Wednesday, on a visit to his brother Robert, who is ill. Mr. Williams only expects to remain in this city for a few days.

HENRY C. BEELER, the State Geologist of Wyoming, has issued a report entitled 'Wyoming Mines, 1907.' It contains a summary of conditions and progress in the copper, gold, iron, asbestos, sulphur, stone, plastic minerals, gravel, oil, natural gas, and coal industries of the State; it is well illustrated with Wyoming views.

General Mining News.

ALASKA.

(Special Correspondence.)—Nine well-defined copper lodes have been developed in the Sawtooth range, 30 miles north of Nome. The croppings assayed as high as 15 per cent. Alaska has now three separate copper belts in the Seward Peninsula, in addition to the Copper River district.——The "No. 11 above" claim on Cleary creek in the Tanana district has been sold for $135,000.——Estimates from the Seattle assay office indicate that the output of gold from Alaska during 1907 will exceed $18,000,000.——At Nome, preparations are being made for the erection of sampling works, so that quartz miners can get returns without shipping direct to distant points. The three banks of Nome have formed a clearing house and issued certificates. Currency is scarce, but the banks have ample reserves.

Nome, Feb. 1.

ARIZONA.

COCHISE COUNTY.

The Apache group of claims in the Old Hat mining district is being steadily developed by a force of 25 men. At present a tunnel is being driven through the property and it has already reached a depth of 400 ft., while a shaft has been sunk to the 150-ft. level.——At a meeting of the stockholders of the Shattuck-Arizona Mining Co. a vote was carried unanimously that the company advertise immediately for bids for the construction of an 800-ton smelter to be erected at Douglas, Arizona. Development work has been carried on steadily and shipments were made until the smelters refused to take any more custom ore.——Grading for the new Alaska mill at Congress is finished, and D. J. Sullivan, president of the United Mines Co. is in California purchasing machinery. The mill will have four Nissen stamps with concentrators and cyanide plant. The Alaska is a promising property, and is opened to a depth of more than 400 ft. and developed by 1000 ft. of drifts. The ore is of the same character as that in the Congress mine, which is about half a mile farther east. The vein runs east, dipping 30° north. Five claims comprise the Alaska group, which adjoins the town of Congress on the north. The railroad from Congress Junc. to Congress passes within a short distance of the Alaska working shaft and mill-site. The company also owns the Chicago group of claims, five miles west of the Alaska, and these will be developed later.

The Pennsylvania & Arizona Mining Co. have found ore assaying over $100 per ton in gold at their mine about 10 miles north of Morriston in the Pichaco district. The vein seems to be as wide as the shaft.

At Tombstone a compressor is being installed at the Emerald mine, where a large body of copper ore has been recently opened up. Compressed air will be used for machine drills and also for a hoist at a winze that is being sunk to determine the depth of the orebody. At the Big shaft, the work of enlarging the station on the 1000-ft. level for the installation of the pumps has been completed and the machinery is expected shortly. The pumps are handling about 4,500,000 gal. daily.

MOHAVE COUNTY.

The milling plant recently put in at the Victor mines south of Gold road is running successfully. Power is obtained from Needles. The water for the milling plant is pumped from a point near Spear's lake, a distance of about nine miles. The station is capable of delivering enough water at Vivian to supply all milling and domestic needs of that camp, as well as that of the Victor company.——Rich ore has been found by J. Carter at a depth of 60 ft. on a claim about half a mile from the Victor property.

SANTA CRUZ COUNTY.

The smelting plant of the Imperial Copper Co. at Sasco has been completed and blown in. The furnace has a capacity of 350 tons per 24 hr. and the plant is built so that it can be easily enlarged.

CALIFORNIA.

BUTTE COUNTY.

The Ophir Gold Dredging Co. has purchased the property of the Nevada Gold Dredging Co., which includes two dredgers and 250 acres of ground.

INYO COUNTY.

(Special Correspondence.)—The Keane-Wonder mine and mill are situated on the Death Valley slope of the Funeral range, 25 miles southwest from Rhyolite, Nevada. The property is managed by Homer Wilson of San Francisco. The original workings were carried on through adits, but at present the bulk of the ore is quarried from open cuts. The strike of the vein follows the trend of the range and has a dip to the south. The country rock is a schist and the vein material consists of a ruby quartz, carrying free gold running from $10 to $30 per ton. An aerial tramway about a mile in length conveys the ore from the mine to the mill, making a descent of 1300 ft. in that distance. The

Map of California.

longest span between towers is 1200 ft. The rock crusher, stationed at the upper terminal, is operated by the power generated by this gravity tramway. The mill, which handles 100 tons per day, has 20 stamps, amalgamating plates, concentrating tables, and equipment for cyanidation is being put in. The tables serve the purpose of taking up the small proportion of lead that occurs in the ore. Water for mill work and other purposes is pumped from wells by gasoline engines. Steam power is used for the mill, crude oil being used as fuel under the boilers.

Keeler, Feb. 22.

NEVADA COUNTY.

(Special Correspondence.)—Several small pockets of rich ore have been encountered in the Pennsylvania-W. Y. O. D. mine. Extensive exploration work is being carried on.——High-grade quartz continues to come from the Kenosha mine. A small force is engaged in sinking the shaft and prosecuting development work. The vein shows improvement.——Extensive exploration is going on at the Sultana group.——Excavating for the engine room and head-frame at the Midas mine has been completed, and work has been resumed on the shaft. It is expected that the orebody disclosed in the old James Bros. workings will be encountered by the new shaft within three weeks.——Limited development work is going on in the Spring Hill property. A tunnel is being driven along a large vein of low-grade ore.

Three or four men are employed.——The ore-shoot near the 500-ft. level in the Idaho-Maryland has widened to 19 in. and ten stamps are running on ore coming from this point. Several additions have been made to the working force and the mine is being energetically developed.——A splendid body of ore has been cut by the Central shaft. The 80-stamp mill is continuously running on good ore.——Work has been resumed on the Gaston tunnel, six men being employed. The adit is in 1800 ft. and it is expected to intersect the vein at a distance of 2000 ft. The tunnel will strike the ore at a depth of 3000 ft. Frank Foley is directing operations.——At the Golden Gate good ore is being developed.——It is announced that work will be resumed at the Grey Eagle mine early in March. The mine has been closed for several weeks owing to the freezing of the water-system and a break in the ditch.——The shaft at the Mountain View mine is going down in good ore. A few stamps are dropping, but the mill will not run at full capacity until spring. E. B. Miller is superintendent.——At the Omega placer mine, rich gravel is being developed. Several men are employed.——Colonel George Stone is expected to arrive in Nevada City soon to inspect the Merrimac mine, southwest of that city. It is rumored that work on the

View From Head Frame, Empire Mine, Grass Valley.

Merrimac will be resumed if the inspection is satisfactory. ——The Grass Valley and Nevada City mining districts are still over-crowded with miners. Many old residents who have been working at other trades in San Francisco and other points are returning, owing to their discharge from their positions in the cities.

Grass Valley, Feb. 24.

The fire in the Brunswick mine has been extinguished and the damage was only trifling. The lagging in the pump-station was burned and the wiring damaged. The motors and pumping machinery, however, were not damaged at all, and as soon as the necessary wiring was repaired, the pump was started and the motors and other machinery were found to be in good condition. The motors, two 40-hp. machines, were on cement foundations and some little way from the burning woodwork.

Six men have been put to work to drive the low level adit from Poorman's creek to the Gaston mine. It is now 1800 ft. long and there is still 2000 ft. to be driven before reaching the vein, which should be cut at 3000 ft. below the outcrop. An air-compressor has been installed and two shifts are at work.——The clean-up at the Idaho-Maryland mine showed a marked improvement in the grade of ore treated. The average value, exclusive of concentrates, was $22.50 per ton. The mill has 10 stamps.

A prospectus has been issued by the Iron-Clad Gold Mining & Milling Co. in which it is stated that the mine will be equipped with extensive machinery, including compressor, pumps, and a 20-stamp mill. A generator and Cornish pump are also contemplated.

PLACER COUNTY.

The dredger at the Cash Rock is finished and lies moored at the mouth of the Dardanelles canyon. The boat is 85 ft. long, 40 ft. wide, and 7 ft. deep. It is designed by Du Bois, who is operating a similar suction dredge at Middle creek, Shasta county. A diver works on the river bottom and removes the large boulders with a grappling-hook. The dredger will start work in April.——The Bellevue mine at Ophir has been bonded to Reno capitalists, who are starting development work by sinking a shaft.

SHASTA COUNTY.

A group of claims between the Niagara and Washington mines has been purchased by A. Geiser of Baker City, Oregon. A carload of tools has been shipped to Redding for development work.——While cross-cutting from the Trindath tunnel at the Washington mine, a new vein of good ore was discovered. This was about 150 ft. nearer than the vein which forms the objective of the cross-cut.

High-grade ore has been found in the Uncle Sam mine by F. Maxwell, who is working under a lease and bond. This mine ranked among the greatest producers in northern California, but recently the ore has become refractory and of low grade. The veins are wide and the mine should have an important future, if new ore-shoots can be found or the old ones worked deeper, as there is a growing demand for silicious ores at the smelters at Kennett and Coram, both within six miles.

The smelter at Delamar will be started up at the begin-

Empire Mine, Grass Valley.

ning of March. The completion of the railroad to Delamar will open up a large area covered by copper prospects. The Bully Hill Copper Co. has been steadily developing its mines during the last two years, and two 3-compartment shafts have been sunk. One is on the Bully Hill claim and this is 970 ft. deep, and the other, 800 ft. deep, is on the Rising Star. The smelter has been remodeled and now has two large blast-furnaces and one reverberatory, giving it a capacity of about 800 tons per day.——The reorganization of the Balaklala Copper Co. is proceeding satisfactorily, and all outstanding indebtedness being paid. It is expected that work will be resumed as soon as the weather improves. ——At the Mammoth smelter at Kennett the two new blast-furnaces are nearly completed and will soon be started up, together with the converter plant. Silicious ores will soon be shipped from Utah to be smelted with the basic ores of Kennett.

TRINITY COUNTY.

Hydraulic mining has been started at the Union Hill mine between Lewiston and Douglas City. The 100-ft. tunnel to convey debris from the Weaver Creek basin to the Trinity river was completed several weeks ago. Since that time a 5-ft. flume has been laid in the tunnel, through which the debris is discharged. The Union Hill is the largest hydraulic mine in Trinity county, with the exception of the La Grange, which is more extensive but not so rich.

TUOLUMNE COUNTY.

Work has been begun to drive an adit on the Ryan mine above Sugar Pine.——The United Mines Corporation is working 30 men on the New Albany. Good progress is being made on the construction of the new 20-stamp mill.

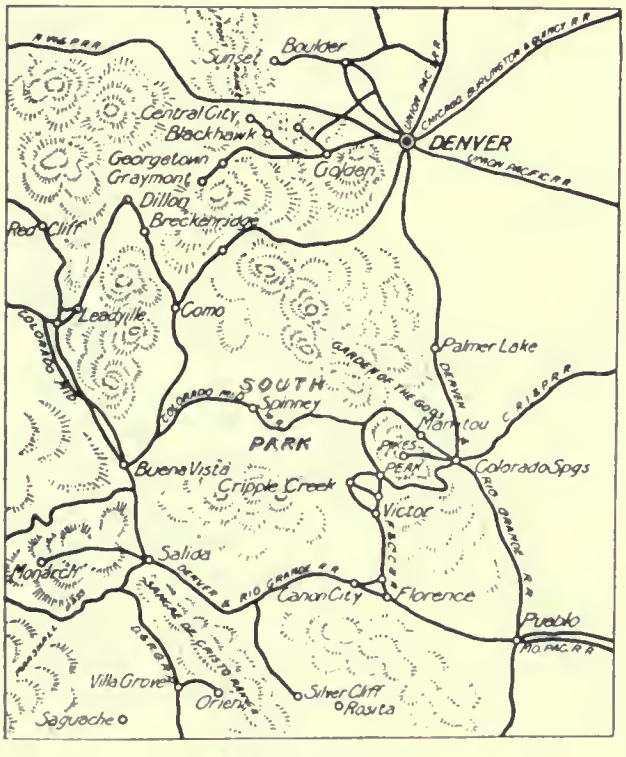
COLORADO.

CHAFFEE COUNTY.

A company has been formed to drive a low-level drainage adit to tap the mines near Granite. The tunnel will be 3000 ft. long, according to present plans. It will connect with the mines at about 300 to 400 ft. below the present workings. The tunnel starts on Pass creek and has already been driven over 100 ft. It will run in a southeasterly direction and should cut 11 known veins. The mines that will be drained are the Yankee Blade, Majenta, Robert George, New Year, Bunker Hill, Washington, Gophir, and Young America. These mines have produced about $1,000,000 worth of ore assaying about $65 per ton. None of these mines have been worked more than 250 ft. deep. The company owns six claims and has options on a number of others.——Rich ore has been found on the east drift of the Margaret mine at a depth of 50 ft. in a vein 3 ft. wide. A shipment of ore has been made to the Salida smelter, but returns have not yet been received. The mine is to be equipped with a power hoist in the spring.

LAKE COUNTY.

About 50 tons per day of zinc tailing are being shipped from the old A. Y. and Minnie dump to the zinc smelter



A Part of Colorado.

at Pueblo.——Important developments are being made in the Miller group of claims on Champion Mtn. in Lackawanna gulch. Last year a shaft was sunk from the south side of the mountain, but the work was abandoned owing to the water. Rich ore had been struck, and so a tunnel was driven from the west side of the hill, and this has reached the vein, which is richer than it was in the shaft. A mill has been erected at the mine.——Development work is being carried on at the Coronado and shipments are made regularly. The workings are all above the 600 level and water has not been encountered.

TELLER COUNTY.

Under the new contract let by the Cripple Creek Drainage & Tunnel Co. for the completion of the Gatch Park tunnel, the dimensions of the tunnel are changed from 10 ft. high by 6 ft. wide to a height of 6 ft. and width of 10 ft. The rate of progress is to be 750 ft. in each three months until the intermedite shaft is finished, after which 1500 ft. will be required until the connection is made.——H. McGarry has issued a report to the stockholders of the United Gold Mines Co. showing that 4321 tons of ore of a gross value of $123,351 were shipped last year. The net proceeds to lessees were $60,644, and to the company $26,067 in royalties. In addition the company received by settlement of the Londonderry litigation $35,156, making a total of $61,223 for the year. The money in the treasury is to be devoted to the further development of the company's territory.

Another discovery of importance has been made on the Ellen McGregor claim of the Fair Chance Gold Mining Co. on Gold hill. Shipments have been made containing as much as 309 oz. silver per ton. At present the vein is more than a foot wide and assays over 100 oz. silver per ton.

E. C. Metzaer and I. Downing have secured a lease on the property of the Jennie Sample Mining Co. Under the conditions of the lease, which is of three years duration, the shaft is to be sunk 100 ft. each year, and at least 90 shifts' work performed each month. The royalty is 2% on the net smelter and mill returns, and it is required of the lessees that they employ no men who do not hold one of the new recommendation cards of the Mine Owners & Operators Association.——Shipments have been made by L. A. Van Tilborg, who is a lessee on the El Paso Con. Co.'s estate, and by the Columbia Mining & Development Co., operating the Chicken Hawk mine on Guyot hill.

An important discovery has been made on the grounnd owned by the Cresson Con. Gold Mining & Milling Co. on Raven and Bull hills. Cross-cutting in a northeasterly direction from the 600-ft. level of the main shaft, a new vein was recently encountered, and has been traced for a length of 65 ft. and it has a width of 6 ft. The first two carloads shipped realized $110 per ton. The present development work shows an improvement in the quality of this important find.

The Royal group of mines in the Bridal Veil district has been bonded to R. D. McClelland. The group is composed of seven claims.

IDAHO.

IDAHO COUNTY.

Rich placer ground is reported to have been discovered in Baker gulch in the Elk district.——The new plant at the Buster mine has now been running a week. The tailing goes direct from the concentrators to the cyanide tanks. ——High-grade ore has been found by S. Simmons in the Hope group of mines. The ore is rich in sulphides carrying gold.

SHOSHONE COUNTY.

(Special Correspondence).—Active operations at the famous Snowstorm mine at Mullan were resumed Feb. 20, after a period of four months of inactivity. The Snowstorm closed down its main workings last November. Five smelters are now on its shipping list, comprising the Tacoma, the Granby, the B. C. at Greenwood, B. C., the Amalgamated at Great Falls, Mont., and the Butte Reduction Works, at Butte, Mont. Some ore has been going to the latter plant during the past four months, but only a small tonnage. During the interval of its cessation occasion has been taken to largely remodel and improve the plant, both at the mine and mill. At the mine a 20-drill air-compressor has been installed, to be run by electric power, and a 300 hp. motor. This is to take the place, when water is low, of the water-power compressor which has been in use in the past. At the mill four motors have been installed, replacing the steam plant. New quarters have also been completed in the meantime, equipped with steam heat, baths, laundry, dry-rooms, etc., capable of accommodating 300 men. The ore from the Snowstorm, which is silicious, is used principally for converter linings, and as such as wonted by individual smelters in limited quantity. That five of the principal plants of the Northwest have now made contracts with the Greenoughs indicates a better outlook.——The Treasure Hill Mining Co. has been incorporated in Spokane, and will take over the Butterfly group of quartz-gold claims in the Elk City gold belt of central Idaho. The properties were owned by Robert Puelz of Elk City. A valuable discovery of gold was made in the Butterfly during January, and it is looked upon as a promising property. Mining operations will be commenced

as soon as weather conditions permit the bringing in of machinery. Development consists of tunnels and shafts on each of the eight claims.

The Idaho Smelting & Refining Co. has taken an option on the Snowshoe lead-silver mine of the Libby district in western Montana, and has sent an engineer to examine the property. The Snowshoe has produced $800,000 worth of ore, but for two years it has been in litigation. This has now been settled, and the mine is ready at a moment's notice, it is said, to resume operations, the machinery and electric lighting plant having been kept in good condition. ——The smelter of the Idaho Co. situated at Ponderay, Idaho, has been undergoing repairs and enlargement preparatory to blowing in. A large supply of ores and material is now on hand, and it is expected that operations will be begun soon. The plant ran for a time last year, but was closed down after having become involved heavily in debt.

Spokane, Feb. 23.

The route selected by the St. Paul, Minneapolis & Seattle Electric Railway Co. for its new line will pass through Wallace, down to Harrison, and thence direct to Spokane. The route, which is said to be 200 miles shorter than any other from St. Paul to the coast, will not pass through Butte.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—It is estimated that there are 800 men now at work at the mines and mills of Goldfield. ——Frank Oliver of the Little Florence mine was recently in Salt Lake, where he secured over 100 more miners for that property. They come as machine-drillers and timbermen, and are to receive $4 and $4.50 per day, respectively. ——The lessees on the Little Florence have a lease that runs 68 days longer. When it expires their employees will doubtless be received by the Consolidated company. The Utah miners, who are out of work, seem to be glad of the chance to get work, and those who come renounce allegiance to the Western Federation of Miners.——It is reported that the Allis-Chalmers Co. has secured the contract to furnish the machinery and equipment for the mill to be erected by the Goldfield Con. Mines Co. The proposed mill is to have 100 stamps, with amalgamating plates, concentrating tables, and cyanide equipment.

Goldfield, Feb. 24.

A new vein has been discovered in the 900-ft. level of the Belmont mine at Tonopah. The width of the ore is not known, but it assays about $50 per ton.——Shipments for the week ending Feb. 15 in the Tonopah district amounted to 4125 tons. The Tonopah Mining Co. shipped 3113 tons to Miller; Belmont 895, and McNamara 117 tons. ——On the Copper Spot claim in the Golden Arrow district rich ore has been found in a vein with a strike northwest and dipping southwest. The ore is 6 ft. wide and assays $40 per ton.

LINCOLN COUNTY.

On the Esther claim at Searchlight another vein of rich ore has been found, 300 ft. north of that recently discovered.——The Chiquita Con. is increasing its force. It is stated that the ore improves in quality near a fault which has been recently encountered.

NYE COUNTY.

(Special Correspondence).—The Bonnie Claire mine and mill were closed down a short time ago, chiefly because there was no market for the ore and concentrate. In the meantime the property has been placed in the hands of a receiver. The suspension of operations is considered only temporary. The mill is equipped for amalgamation, concentration and cyanide treatment. The ores carry gold, silver, and lead, the last named being recovered on the tables in the form of a high-grade concentrate, being partly galena and partly oxidized ores. The mill is at Bonnie Claire station on the L. V. & T. railroad, and the mines are 8 miles away. The mines are in four groups in close proximity to one another—the Rattlesnake, New Century, Eva May, and Corbet. The mine is extensively developed by adits and shafts. F. H. Vahrenkamp is general manager.

Tonopah, Feb. 23.

(Special Correspondence).—The Combination mill of the Goldfield Con. Mines Co. is treating 90 tons of ore per day, recovering over 92% by amalgamation, concentration, and cyanidation. The ore contains about three ounces of silver per ton and the rest in gold. Since A. G. Kirby took charge of the mill the method has been considerably modified. From the crusher the ore passes to the 20 stamps reduced to 1½-in. size, together with much fine material. The battery screens are 16 mesh, through which the pulp passes to plates, thence to tube-mills which pulverize to 100-mesh. Then it is pumped up to cone classifiers, the overflow from which is again passed over plates. That from the bottom of the classifiers is reground in the tube-mills, then elevated to classifiers again, the overflow from this second classification passing to the lower part of the mill over canvas tables, thence to settlers, and then into the agitating tanks, where it first comes in contact with cyanide solution; the underflow product of this second classification goes to Frue and Triumph vanners for concentration, the tailing from the vanners being conveyed to the sand tanks for cyanidation. The slime from the agitators is passed through Butters vacuum filters, thence to a Smith-Valie filter-press for taking up the flocculent slime before passing the solution to the precipitating boxes. In the slime tanks centrifugal pumps are used to agitate the slime. The concentrate consists of a complex sulphide including iron and other base metals.

Goldfield, Feb. 21.

(Special Correspondence).—The Johnny mine and mill are situated 12 miles from Armagosa station on the Las Vegas & Tonopah railroad. The mine is opened by an incline, which follows the dip of the vein to a depth of 700 ft. with 7 levels running from it on the vein. The mill contains 8 Nissen stamps with amalgamating plates. The ore is free-milling and averages about $15 per ton. A gyratory crusher reduces the ore to the proper size for the stamps. The power is supplied by three Fairbanks-Morse gas engines that use crude oil for fuel. The cost of this is 10 c. per gal. and it is found to be more economical than distillate or gasoline. There is one engine each for the mill, air-compressor, and hoist.——The Montgomery-Shoshone mill at Rhyolite is treating 250 tons of ore per 24 hr. and shipments of high-grade ore make up a total production of 300 tons per day. The hoist over the 600-ft. shaft is operated by steam power, crude oil being used as fuel, but the air-compressor and mill machinery are run by electric power transmitted from the power plant at Bishop Creek, California. A 15 by 24 Blake crusher reduces the ore to 1-in. size, and it is then treated by three sets of rolls, each 14 by 42 in. diam., the first set crushing to ⅝-in., the second to ¼-in. size, and the third to 16-mesh. The product from the rolls is elevated and sized by revolving trommels, the oversize in each case being re-ground until all is reduced to at least 16-mesh. Much of the ore consists of an oxidized material and 80% of it will pass a 40-mesh screen after grinding in the finishing rolls. After being reduced thus the material passes over amalgamating plates and thence to two Dorr classifiers which separate the slime and sand. The sand from these classifiers passes to Wilfley tables and the slime passes through a settling cone to Frue vanners. The resulting concentrate is largely an oxide of iron, carrying gold with a little sulphide. The silicious middling and tailing from the tables pass to sand vats for leaching and the tailing from the vanners is cyanided in agitating tanks, the final slime being passed through Butters vacuum filters. The metal in the solution is precipitated in ordinary zinc boxes. There are five sand-leaching vats, each 36 ft. diam. by 6½ ft. deep, and the agitating tanks are 28 ft. diam. and 16 ft. deep. Blaisdell excavators are employed in discharging the sand vats and mechanical agitators are used in stirring the slime. The ore of this mine consists of rhyolite and quartz, carrying gold and silver, and the methods of amalgamation, concentration,

and cyanidation result in a high saving. Donald B. Gillies is manager and B. W. Turner is superintendent.

Rhyolite, Feb. 23.

Tungsten is reported to have been found in the New Florence district. A number of large lodes are said to occur.——The Gold Bar has made the first clean-up at the mill. The capacity of the mill is 45 to 50 tons per day and the ore assays $15 per ton.——The Montgomery-Shoshone mill has shut down for some alterations. Amalgamation will be discontinued and the ore treated by concentration and cyanidation only. Development work proceeds steadily and about 45 tons of high-grade ore are shipped daily.——A six-drill compressor and machine-drills have been ordered for the Homestake mine. A full force has been at work at the mill since the weather improved.

A cross-cut is being driven on the M. & M. lease on the Great Western at the 140-ft. level. The ore on the 90-ft. level averages $25 per ton.——The framework for the mill of the Round Mountain Reduction Co. is completed and the works should be ready to receive ore within four weeks. Water will be secured from wells 4000 ft. away and a head of 188 ft. will be secured.

NEW MEXICO.

SOCORRO COUNTY.

(Special Correspondence).—The Last Chance mine of the Ernestine Mining Co. of Mogollon has just opened 12 ft. of $25 ore on the 11th level west, 1000 ft. below the surface. This ore contains equal quantities of silver and gold. This property produced over 50% of the gold and silver sent out from the Territory during the last two years. The present ore reserve guarantees a steady production for at least five years. The ore is treated in a 20-stamp mill, this being followed by concentration and cyanidation, the sands having a six-day leaching, while the slimes receive a thorough agitation and are then sent to the Moore filter plant. Fifty men are employed on this property. E. Craig is president. ——The Top Mining Co. have equipped their shaft with a 25-hp. gasoline hoist and a 10 by 12 compressor. The shaft is down more than 200 ft. in ore of milling grade.——Abe. Peterson, one of the owners of the Iron Group, is running in a tunnel from the White Water side to connect with the shaft on the Iron Bar. Some high-grade ore has been taken from this shaft.

Socorro, Feb. 21.

At the Laura mine in the Steeple Rock district shipments of rich ore containing $1200 per ton have been made. Some tons of this ore were stolen and hauled away by teams at night and shipped to the smelter, but the thieves left the country before getting payment from the smelter. ——The discovery of an outcrop of rich ore 2 ft. wide is reported at a point 90 miles southwest of Wickenburg and 12 miles west of Mesquite Wells.

OREGON.

BAKER COUNTY.

Development work is progressing rapidly at the Iola Gold Mining Co.'s mine in the Greenhorn mountains. As soon as the weather improves, a compressor will be installed and the work of driving the adit continued. This is now 350 ft. in length and will be driven 1400 ft., when the vein should be found at a depth of 800 ft. from the surface. The deposit is a large one and the ore is of good milling grade.

UTAH.

JUAB COUNTY.

Developments on the 1800-ft. level in the Lower Mammoth mine show that a large body of rich silver-lead ore occurs at that depth. It has been followed for 125 ft. and its limitation has not yet been reached. The other dimensions cannot be found until the shaft is sunk farther, owing to the water.

SUMMIT COUNTY.

The annual stockholders' meeting of the Daly West mine was held in Denver recently and the following particulars published: The output had a net value of $771,679. This included 673,890 lb. copper, 8,086,456 lb. lead, and 1,042,062 oz. silver. Dividends amounting to $378,000 were paid, and the cash on hand is $313,967. The average assays of the crude ore were as follows: Silver, 43.13 oz.; gold, 0.0423 oz.; lead, 13.43%; copper, 1.4%, making an average total value of $28.51 per ton for the year's output.

WASHINGTON.

FERRY COUNTY.

The ore being shipped from the Insurgent mine assays about $35 per ton. The drift has reached a point under the shaft, which was sunk as far as the Lone Pine adit. G. B. Dennis is president of the company. The water in the Lone Pine workings has been lowered 40 ft. There are about 300 ft. of drifts, besides raises and stopes, to be drained, which will require two weeks of pumping.——The No. 3 adit of the Copper King mine is in 273 ft. and is to be driven about 100 ft. farther.——The Colville Mining & Smelting Co. has had two Merberry rotary furnaces hauled to the South Half group at Park City.——The No. 3 Mountain Boy adit is in 270 ft. The No. 4 adit cut stringers of ore when 600 ft. from the portal, but as yet the vein has not been found.——The Summit adit is in 50 ft. A. C. Cook is superintendent.——An important but unexpected discovery of ore containing gold, copper, and lead is reported on the Byrne group in the Keller district. The ore was found in the adit of the Silver Creek Mining & Milling Co. at 40 ft. from the portal.——Another valuable find has been made on the Papoose claim in Keeno gulch, a mile north of the Congress mine. A tunnel was driven 70 ft. and 20 ft. of it is in heavy galena ore. The ore has been found within 150 ft. of the boundary between this claim and the old Roaring Eagle claim. The discovery on the Papoose was made by J. A. McJunkin, superintendent of the Paymaster mine.——The Silver Tip Con. Mining Co. owns ten claims on Iron Mtn. and Mineral hill. A vein containing quartz with gold and silver and about 4% lead has been opened by cuts and an adit. Work has been resumed in an old adit and a good body of ore found at a depth of 50 ft. A lower adit has been started and development will be continued to find the ore at greater depth. The ore is siliceous and contains argentite, galena, and mispickel. Some samples assayed as high as 257 oz. silver and $24 gold per ton, and 7.2% lead. The company is planning to put up a compressor plant and use machine drills for development.

STEVENS COUNTY.

In the Globe mine a body of ore was encountered over a month ago, and this is being developed by drifting on the vein.——A body of ore 6 ft. wide has been found on the 100-ft. level of the Defender mine and a drift has been started on it.——Regular shipments are being made from the First Thought mine to the smelters at Tacoma and Northport.——A group of 20 claims on First Thought hill will be actively developed by New York capitalists.—— Work has been resumed on the Trojan mine. Before stopping work a vein was discovered in adit No. 3, and now this will be exploited and the adit continued about 500 ft. to reach the main vein. L. Larsen of Orient is superintendent.

CANADA.

BRITISH COLUMBIA.

At the Granby smelter the entire eight furnaces are again in operation. Two of them were out for several days last week while some minor repairs were going on, both at Phoenix and Grand Forks. During that time the tonnage was lessened somewhat, but the Granby mine has already shipped over 100,000 tons of ore this year.——A deep-level adit for the drainage of the mines near Phoenix is under consideration. The work would probably be started from Greenwood and carried on to Phoenix, if the present plans mature.

The Snowshoe mine in Phoenix, operated by the Consolidated Mining & Smelting Co., has just shipped the first carload of copper ore since the closing of the property last November.——The following shipments were made from the Rossland mines last week: Centre Star, 3060 tons; Le Itol, 1599; Le Roi No. 2, 743, and Evening Star, 30 tons.

Special Correspondence.

LONDON.

Zinc Corporation.—The Elmore Process.—Cornish Mining and Mr. Collins.—Discoveries in the Waihi and Great Boulder Mines.

The erection of the Elmore vacuum plant at Broken Hill for the treatment of zinc tailing belonging to the Zinc Corporation is now practically complete and before long some very interesting results should be obtainable. It will be remembered that last summer the Zinc Corporation found itself in an acutely critical condition. With deference, I am bound to say that this crisis was due to the precipitate policy of the directors and managers, who embarked on this enterprise without full consideration. Stacks of tailing were bought before the process to be adopted was settled upon, and the payments became due long before the Corporation got to work. This was what crippled the resources of the company. The fact that two flotation processes were tried and proved to be valueless is no sort of reproach to the sagacity of those responsible. Rather is credit due to them for enterprisingly testing all the processes on a practical scale, and for dropping them so quickly when they failed to give results. From the directors' point of view it has been urged that these great purchases of tailing before the company was ready to treat them were made with the best intentions, namely, to secure the supply before anybody else. I believe that the Elmore process would have been adopted earlier if the inventor had been on the ground. As it was, the Elmore plant was there without anybody to erect or explain it, whereas the representatives of the other two processes were on the spot and able to advocate their cause. The Elmore plant consists of 16 units, each able to treat 30 tons per day. The one unit that Frank Elmore put up has been working continuously for the last few months, and gives excellent results. The financial condition of the Corporation is still in an uncertain state, and the directors are urging shareholders to take up some more preference shares. Last summer the crisis in the company's affairs was so serious, and the outlook so dreary, that fresh capital could only be raised on very onerous terms. Preference shares to the amount of £182,000 were created. These entitled holders to the whole of the profits until 100% had been paid on them, and subsequently to a cumulative preferential dividend at the rate of 20%, with the right to participate pro rata with the ordinary shares in the division of any further profits. Of these shares 76,000 were taken up by shareholders and 32,000 placed elsewhere. The directors are now trying to dispose of the remainder, by offering a call at par for a similar number during the next six months to anybody who will take some now. The directors hope that by that time the value of the preference shares will be better appreciated. The anxieties of the directors will not, however, be over when the Elmore process is at work, for the concentrate is not exactly popular among zinc smelters, and the method of their treatment or disposal will require careful thought.

In a recent issue you printed some remarks by me on the re-opened Cornish mines. I mentioned that the best and cheapest work in this direction was being done by J. H. Collins at Wheal Kitty & Penhalls in the St. Agnes district. The half-yearly results of this company have been published this week, and some details may be very interesting. The present company was formed in October, 1906. The nominal capital is £35,000, in 70,000 shares of 10s. each, but only 44,000 have been issued, of which 24,000 went as purchase price for the property and 20,000 have been subscribed for in cash. The company took over the crushing and dressing plant from the previous owners, and little money was spent in this direction. Most of the cash raised on the flotation of the company has been expended on shaft-sinking and development of some of the orebodies. During the second half of 1907, 54½ tons of concentrate were sold, realizing £5228, the price obtained being high, showing that the concentrate is of good quality. The current expenses amounted to £4500, thus leaving a small profit on the half-year's work. The company is considering the advisability of issuing further shares for the purpose of pushing the development of the mine. In my own judgment the mine offers an excellent scope for investment, and I hope that shareholders will courageously support a scheme for opening it and providing it with a suitable outfit.

Map Showing Position of Broken Hill.

Mr. Collins is a genuine Cornishman and looks for his mine before he puts up a plant. Some of those who have recently re-opened properties in Cornwall have followed the opposite tack and erected a fine modern plant before making a thorough examination underground.

Announcements of important discoveries in two of our leading gold mines have been made this week. One is at the Waihi in New Zealand, a mine which not only overshadows everything else in that country but takes rank with the greatest mines of the world, on the score both of its extensive character and its good management. The deposit is not a restricted one, nor do the veins tend to pinch in depth, as yet. On the contrary, exploration work continues to open up larger reserves of ore. The present news relates to a remarkable development in the Edward lode at the No. 8 level. This orebody was first discovered in 1906, and it is a sort of west extension of the Empire lode. According to a circular issued in October last, the lode had then been opened up for 445 ft., the average width being 9½ ft., and the gold contents 11 dwt., with 2 oz. silver. The news circulated this week states that the driving has been continued for another 232 ft., and that the lode has increased in

width and contents in an unusual manner. Along the face, the sampling shows the ore to vary from 15 dwt. to 2¾ oz. At two points cross-cuts have been driven through the vein, at one of which the vein is proved to be 48 ft. wide, averaging 1½ oz., and at the other 65 ft. wide, averaging 2¾ oz. per ton. It is no wonder therefore that shareholders are in complacent mood and that there is a flutter in the shares. The other important news referred to is the announcement of an extensive discovery in the Great Boulder Proprietary at Kalgoorlie. Here the 2200-ft. level has opened up well. Over a distance of 300 ft. the ore averages 29 dwt., and at the point of working it carries 70 dwt. per ton. The cabled information says nothing about the average thickness, but we may take it for granted that the vein is of the width usually found in this district. The discovery of a rich body of ore at so great a depth is an important event at Kalgoorlie, and it should have some influence on the economic conditions ruling in that camp. For instance, it may cheer Mr. Herman Landau, whose gloomy forecast of the future of West Australian mines I referred to in a recent letter.

Since my name appeared on your editorial page, as representative of the MINING AND SCIENTIFIC

Rawhide, Nevada.

PRESS in London, I have received a large amount of correspondence from your readers in the United States. I grieve to say that I am considerably out of pocket in consequence, for 95% of the letters were insufficiently stamped. It is a standing grievance in England that letters from America hardly ever bear sufficient postage. For many years it has been taken as a small, but none the less true, sign of a happy-go-lucky method of conducting business affairs which is characteristic of the American. Nature has endowed the United States with vast animal, vegetable, and mineral resources, and the country could not help but be rich. Unfortunately the inhabitants attribute their wealth, not to the prodigality of nature, but to their own superior wisdom, shrewdness, and ability. The fact of the existence of a financial stringency shows that there is something wrong that more than counter-balances the natural advantages of the country. So, please, readers of the MINING AND SCIENTIFIC PRESS, begin to reform your business methods by properly stamping your foreign correspondence, and no longer give yourselves a bad character abroad. The above remarks look very unkind, but they are not a quarter as bad as the usual American criticism of British methods and institutions. Another point with regard to the correspondence that I have received: Most of it consists of invitations to participate in mining deals or to place shares in American corporations in London. I may as well say at once that I do not undertake this class of business, financial operations not being in my line.

RAWHIDE, NEVADA.

Latest News.—Extent of the District.—Good Widths of Milling Ore.

The first location on Baloon Mtn., on which some of the best claims are situated, was made on February 17, 1907, and stakes were driven on Grutt Hill to the north during February and March, 1907. The results of prospecting were kept quiet until certain options and leases had been secured by those who recognized the possibilities of the district. It was not until last autumn that prospectors and fortune-hunters spread all over the district. Last October there were not more than 150 men in the camp, while the recent influx has been so rapid that it is difficult to predict from week to week just how many are here—between 3000 and 4000.

The district is just in Esmeralda county, but near Churchill, so much so that most of the early locations are stated as being in the Regent mining district of Churchill county. The mineralized porphyry extends six miles north and south and two miles from east to west, or about 12 square miles, and it is all covered with locations. The surface shows very little quartz float; near the camp of Rawhide there are boulders of quartz, evidently the result

A Prospect at Rawhide.

of replacement in the porphyry dikes characterizing the district. The mineralized district is an immense uplift crossed by dikes of iron-stained porphyry which, where a replacement of feldspar by silica has taken place, has become mineralized with gold and silver. The iron stain is due to oxidation of the pyrite. The iron stain is the prospector's guide, for gold appears to accompany it through the porphyry. The white talc gouge often is rich. These mineralized dikes are from 20 to 60 ft. wide with streaks of high-grade ore, the whole mass (in some already developed) being a good grade of milling ore. Good ore has been found in half a dozen places from Balloon hill westward as far as the McMann group, about 2½ miles in a direct line. Here a 200-ft. cross-cut has cut the dike, showing about 3 ft. of ore, which when picked is said to be rich enough for shipment. The remainder of the dike is milling ore. These streaks of high-grade stuff often appear as separate veins in a dike, but I think they are due to replacement along shear-lines in the dike. To the southeast the porphyries are capped with basaltic lava. Placer gold has been found in the vicinity, but, owing to the limited amount of erosion and the fact that cloud-bursts (which are characteristic of the desert) are so violent, everything in the canyons is swept onto the desert mesas and spread over a wide area, so that the amount of placer gold to be found is not likely to be large. The gold is extremely fine in the ore and would be hard to save by washing in pans or sluices, although pieces worth 60 or 70 cents have been reported found.

DENVER, COLORADO.

New Rates on Lead Ores.—Activity in Clear Creek and Gilpin.—Oil Strike.—Promoters and Newspapers.—Leadville News.—Progress at Cripple Creek.

The new schedule of rates for the lead ores of Boulder, Clear Creek, and Gilpin counties reeently issued by the Chamberlain-Dillingham Ore Buying Co. at its various samplers in the district is having the desired effeet. Work is being pushed on all the produeing mines with increased vigor. At Central City the Golden Sun Co. is advaneing its main adit through very hard rock at three feet per day. This adit is to be double-tracked and used both as a drainage and transportation outlet. It is now in 900 ft. and when eompleted will be one of the important enterprises of its kind in the district. The Paolo mine in Leavenworth guleh is under bond and lease to Denver and Kansas City parties. They have installed a new hoisting engine preparatory to sinking and development work. The Quartz Mill property in the same guleh has been unwatered by Idaho Springs miners and arrangements made to sink the shaft another 100 ft. The lessees operating on the East Leavenworth mine near Russell guleh have begun aetual mining after nearly a month spent in timbering the shaft, repairing the buildings, and installing the neeessary maehinery. At Idaho Springs, work has been resumed on the lateral leading from the Newhouse tunnel along the Saratoga vein to a point direetly underneath the shaft. At this point a station will be eut and a raise made to the shaft. All the ground in the Speeie Payment mine above the fifth level has been leased to T. J. Johnston and associates of Idaho Springs. It is the purpose of the lessees to sub-let bloeks of ground on favorable terms so that the mine may be brought to full production as soon as possible. The Ward mine, whieh has been unwatered lately for sampling, is being allowed to fill with water again. This is a large low-grade proposition and would require a large produetion to make it profitable. The engineer's report has not been eompleted.

A ease of more than usual interest has just been appealed to the Supreme Court. The treasurer of Boulder county sold the St. Louis mine, mill, and tramway for unpaid taxes of 1900. J. T. Bottom, one of the heaviest stockholders in the company, paid the taxes and seeured the title. In the following year Bottom allowed the taxes to go by default, and they were paid by L. S. Young, who then applied for a tax-title. Mr. Bottom interfered with a petition for an injunetion restraining the County Treasurer from exeeuting or delivering a tax-deed to Young. When the ease was tried before Judge H. P. Gamble on Nov. 29, 1907, the petition for a permanent injunetion was denied but the temporary injunetion was allowed to remain in force until the Supreme Court eould render a decision.

The reeent strike of natural gas at Fort Collins has aroused oil prospeetors in the eastern part of the State. The Pierre formation in El Paso county is being explored again at the Donovan ranch three miles southeast of Colorado Springs. The eontraet for the drilling has been let to N. West of Denver. ——W. W. Degge, a Boulder promoter, and his various corporations are defendants in a suit before the District Court of Denver. The complainant is the Mining Investor Publishing Co., proprietor of the *Mining Investor*. It is alleged that Degge connived in the theft of the subscription lists of the *Mining Investor*. The ease is directed against Degge, the Wellington Association, the Wellington Investment Co., and the Wellington Realty Co. The *Daily Mining Record*, of Denver, which has been advertising these companies extensively, excluded the advertising matter of these companies as soon as the facts were known. This is all well enough after all the possible damage has been done. If the *Daily Mining Record* is really working for the good of the mining industry, it should require some proof from the companies that it advertises that they are legitimate business enterprises. The same is true of the *Investor*; both are incubators of wild-eats.

Leadville is rejoicing because the Tuscan mine, one of its steady producers, is again in the aetive list. A small force of miners has been put to work and the force will be increased as the market conditions permit. The Dinero Co. has eompleted the examination of its property in the Sugar Loaf district and is now advaneing its adit into the mountain as rapidly as possible. The adit is in 2255 ft. and has to be extended 1220 ft. more before it comes under the old Dinero shaft. This shaft, although it showed good ore, had to be abandoned on aeeount of water. The Modoc lease on Carbonate hill has been taken over by a new set of lessees, who have retimbered the shaft for the first 400 ft. After eompleting the remaining 300 ft. of timbering, the lessees will begin development on the known orebody.

Cripple Creek has been favored with another reduction in freight and treatment eharges. The U. S. R. & R. company has announced a $3.50 rate on ores of $8 and under. This, of eourse, will stimulate the produetion of low-grade ore, and add to the troubles of the transportation companies, whieh are working about to their limit with the present tonnage. The direetors of the Anehor Co. are making a strenuous effort to redeem their property, whieh was sold under sheriff's exeeution last Oetober. The debt is only $3800. The property is well situated. The Deep Drainage Tunnel is being pushed rapidly under the Carlton traet. The best reeord yet made for a single day is 12 ft. The marked increase in the rate of advanee is another illustration of the advantage gained in driving an adit in hard ground by making it wide enough to allow the eut-holes to get a good lift. The width of the adit has been increased under the present eontract from 7 to 10 feet.

GOLDFIELD, NEVADA.

The Consolidated Mines.—Combination and Mohawk Shafts.—Character of the Ore.—The New Mill.—Scale of Wages.

The Combination shaft of the Goldfield Consolidated Mines Co. has three compartments, and connects with six working levels at 80, 130, 180, 230, 280, and 380 ft., respeetively, from the surface. The greatest development appears to be on the two deepest levels, though the workings on the higher levels are extensive, with mueh ore exposed in open stopes. The ore is oxidized down to the 180-ft. level, below which it consists of iron pyrite in a hard quartz gangue. The sulphide appears to grade from the lighter form to the heavier iron pyrite, the gold being disseminated through it in minute partieles, usually invisible. In breaking off the oxidized ore a vast quantity of fine material results, and this is true to some extent of the sulphide stopes. At present air-drills are in use only on the lower levels. The open stopes and reserves show the orebody to range from 15 to 40 ft. in width. The bottom level of the Combination and the 350-ft. level of the Mohawk correspond to eaeh other, the two mines being eonnected at this level. At the Combination a force of about 100 men is employed in mine and mill, and enough ore is being hoisted to keep the mill in operation. In the meantime development is being pushed and ore is being blocked out.

The Mohawk, one of the big mines of the Goldfield

Consolidated, has a 600-ft. working shaft, with three compartments, the levels being at 250, 350, 450, and 600 ft. The Mohawk lode has a strike to the northwest and a dip of 45° east. The shaft cuts through the lode at the 350-ft. level. The ore lies within a dacite zone, the hanging wall being well defined. The width of the zone of mineralization is 360 ft. on the 450-ft. level, but not so wide on the 350. Besides the varying mineralization of the lode as a whole, there are transverse fissures cutting through it, carrying narrow streaks of exceedingly high-grade stuff; there are also well defined chimneys of ore of the highest grade. In some of the worked-out chambers on the upper levels the character and extent of these chimneys were well demonstrated. A winze being sunk from the 450-ft. level on one of these high-grade shoots is to be continued down to the 600-ft. level. This winze follows the ore-shoot. The gangue is a brecciated quartz, carrying the iron

The Town of Rhyolite, Nevada.

pyrite with which the gold is associated. The high-grade streaks, however, carry the gold chiefly as a telluride. The prevailing opinion is that the gold in the sulphide is largely in a free state, and that it is released by fine grinding. In support of this idea it is stated that on the plates following the stamp-batteries the percentage of recovery by amalgamation is low, while the recovery on plates below the tube-mills is comparatively high.

About 90 men are employed at the Mohawk, developing and blocking out ore. The intention is to be ready to hoist and send to the mill about 500 tons per day as soon as the mill is complete, three months hence. It is said, also, that the plan is to make a mixture of all grades of ore and send it to the mill, except the phenomenally high-grade streaks. It is claimed that the tonnage of ore in the mine, blocked out and accessible, is sufficient to keep the mill supplied for years. The ground formerly under the Hayes & Monnette lease, on the upper levels, still contains large pillars of rich ore and important segments of the lode. Development on the 600 level has just been commenced.

The hoisting is being done by electric power at present, though a new double-drum steam hoist is being installed and will soon be ready. It will have a rope speed of 800 ft. per min. The power is to be supplied by two 100 hp. steam boilers, under which oil will be used as fuel. In a separate new building are two Nordberg air-compressors, each having the capacity of 1500 cu. ft. free air per minute, and electrically driven; also a machine-shop and a distributing system for the electric power.

The company has started a new shaft on its Clairmont ground, 1000 ft. east of the Mohawk shaft, which has reached a depth of 300 ft. Eventually the plan of centralizing the hoisting for the entire group will be carried out. The work on the new 100-stamp mill has commenced. The Allis-Chalmers Co. is to supply machinery for crushing, amalgamating, concentrating, and re-grinding; and the equipment for the cyaniding departments will depend upon tests being made by C. W. Merrill.

On the operating staff of the company are the following: J. H. Mackenzie, general manager; E. Hampton, general superintendent; D. C. Wilkinson, engineer; A. G. Kirby, mill superintendent; William Campbell, superintendent of the Combination mine; A. J. Canavan, superintendent of the Mohawk; H. D. Trenam, superintendent of the Red Top and Jumbo mines; John B. Fleming, mechanical and construction engineer. F. L. Bosqui is consulting metallurgist of the company.

A branch railroad is being built to the mill-site, which is near the Sandstorm mine and about two miles from the Mohawk. The company has at this time about 300 men employed at its mines and Combination mill. The wages it pays are as follows: Miners, $4; machine-men, $4; helpers, $3.75; trammers, $3.75; shovelers, $3.75; timber-men, $4.50; pump-men, $4; head blacksmith, $5.50; tool-sharpeners, $5; blacksmith helpers, $4; top-men, $3.75. This is the wage scale adopted by the Goldfield Mine Owners' Association, and while there has been a prospect on the part of one or two lessees to advance the pay of the miner to $4.50, the management of the Consolidated company, the largest employer of labor, announces its determination to stand by the above scale.

RHYOLITE, NEVADA.

The Homestake Group.—The Mine and Mill.—Gold Bar Mine.—Start of New Mill.—Tramp Consolidated.—The Mayflower.

The Homestake-King Consolidated Bullfrog Co. has developed and is equipping a mining property six miles northwest of Rhyolite. The principal lode of gold-bearing ore strikes northwest through a rhyolite country, and has a dip of 76° west. Two shafts have been sunk on the vein, one an incline and the other a vertical shaft, 1300 ft. apart. Both shafts reach a depth of 500 ft. and are equipped with gasoline hoists. The development aggregates some 3400 ft. of work, consisting of shafts, raises, and drifts. The plans contemplate the sinking of a three-compartment working shaft at a point between the two old shafts, opposite the mill now under construction. The ore consists of quartz in an altered rhyolite, with free gold finely disseminated through it, and a little silver. Tests indicate that the bulk of the yield in the mill is obtained from the slime, rather than from the coarse sand. On the 200-ft. level thorough sampling by A. G. Cadogan, the superintendent, showed a vein 50 ft. wide, carrying ore averaging $14 per ton; similar sampling on the 300 level showed the vein to be 15 to 20 ft. wide, the ore averaging $12 per ton; samples from the 30-ft.

vein on the 400 level gave an average of $23 per ton. Rich streaks are said to run from $40 to $100 per ton. The foot-wall is well defined, but the hanging wall is not so definite, the vein-filling shading into the country rock on that side. Development on the strike of the lode for nearly 2000 ft. demonstrates that there are two ore-shoots, both pitching to the north. The mill, under construction, which is to be ready in May, is being erected and equipped by the Colorado Iron Works, represented on the ground by W. B. Milliken and J. F. Gibbs. The plant was designed by John E. Rothwell, assisted by Mr. Milliken. The equipment comprises a McCully crusher, 25 stamps, 1050 lb. each, the battery screens to be 18 mesh, of No. 24 wire. Below each 5-stamp battery is a 12-ft. amalgamating plate in three sections. The pulp is to pass from the plates to Dorr classifiers. The slime from these passes through settling-tanks to Hendryx agitator vats in which cyanide solution is introduced. The sand from the Dorr classifiers is conveyed to tube-mills, of which there are three, each 3 ft. 9 in. diam. by 15 ft. long, having steel lining of the El Oro type. The pulp from the tube-mills passes over a second set of amalgamating plates, thence to Dorr classifiers again. The slime from the latter goes to the agitator vats and the sand is re-ground in the tube-mills and passes thence to the Hendryx agitator, except that a portion of the coarser sand may be cyanided subsequently. The final slime treatment is in Butters filters. Thus it is seen that provision is made for almost all-slime treatment. It is believed that 80% of the saving will be by amalgamation. Tests pretty well indicate that by amalgamation and cyanide a total extraction of 94% can be made. It is figured that the ore will average $15 to $18 per ton. The mill will be operated by electric power. The president of this company is B. D. Milan of Dallas, Texas, with Con. O'Donnel as general manager, A. G. Cadogan superintendent.

The Gold Bar Mining Co. has a well developed mine end-lining with the Homestake group. The Gold Bar was the earliest location in this part of the district and has been for three years under the superintendency of L. E. Bedford. J. P. Loftus of Goldfield is president, J. R. Davis general manager; L. M. Louis is construction engineer, under whose direction the mill was built; W. H. Royston is in charge of the mill. The mine is opened by means of an incline shaft 550 ft. deep, with stations at the 50, 150, 250, 350, 450, and 550-ft. points. Levels on the vein from the second, third, and fourth of these stations aggregate over 5000 ft. of work. Stopes have been started above these levels. The vein, as exposed on the 150-ft. level, is 5 to 6 ft. wide; that on the 350 level being 30 ft. in width. The character of the ore in this mine is similar to that in the Homestake, as described above. A general average is placed at $15 to $16 per ton. The hoisting is done by gasoline engines. The mill has a crusher, 10 stamps, and a Huntington mill. Following the stamps are plates, all the pulp passing over the latter being re-ground in the Huntington, this being followed by a second set of plates. The mill machinery is operated by electricity from the lines of the California Power plant. The mill has been operating but a week or two and results are proving that the ore is ideal for treatment by amalgamation. Water is pumped from springs four miles away to a tank near the mill, electric pumps being used.

The Tramp Consolidated Mines Co. has a group on Bonanza Mtn. overlooking the town of Rhyolite. It is the consolidation of the Hobo, Tramp, Eclipse, and Denver claims, and is being developed through the Denver adit. C. N. Gardner is the superintendent. There are three adit levels, the lowest of which attains a depth of 600 ft., the workings on the three levels being connected. The vein is said to have an average width of about four feet.

The Mayflower mine, superintended by Robert Smith and situated five miles north of Rhyolite, is opened to 500 ft. by an incline shaft and drifts on the vein at various levels, showing a well-defined orebody, carrying free-milling gold ore in a rhyolite-quartz gangue. Eventually a mill will be built. The Bullfrog-Pioneer Mining Co. has a property in the same part of the district, a portion of it being under lease to the Bullfrog-Pioneer Leasing Co., managed by G. K. Vaughn. Development shows a vein 40 ft. wide in places, with 20 ft. of ore, opened by levels from the surface. The ore is characteristic of the district generally. The lessees are erecting a mill, the equipment being a crusher, rolls, screens, and cyaniding facilities. The others concerned in the leasing company are J. R. Bryan, T. A. Fleming, and F. H. Stickney.

SALT LAKE, UTAH.

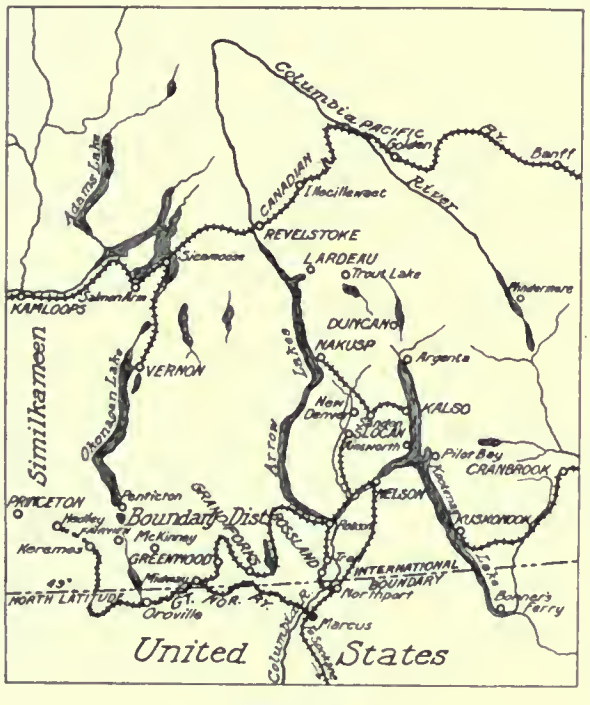
Annual Report of the Daly-West Mining Co.—The Yampa Smelter.—Phoenix Co.—Bingham-New haven Co.—Utah-Apex Property.

The annual election of shareholders of the Daly West Mining Co., held at Denver, resulted in the re-election of the retiring board of directors. During the year 1907 the company treated or shipped 24,856 dry tons of ore. From 8521 tons of crude ore was produced 243,061 lb. copper, 2,289,598 lb. lead, 360 oz. gold, 367,531 oz. silver, which sold for $242,959. From 7480 dry tons of concentrate was produced 229,250 lb. copper, 4,211,972 lb. lead, 305 oz. gold, and 407,968 oz. silver, the same selling for $162,315. The recapitulation shows that the mine produced 673,890 lb. copper, 8,036,456 lb. lead, 949 oz. gold, 1,042,062 oz. silver, the total net value of which was $771,679. The average assay of the crude ore was: Silver, 43.13 oz. per ton; gold, 0.0423 oz.; lead, 13.43%; copper, 1.4%; the net selling value being $28.51. In the concentrate there was: Silver, 54.54 oz.; gold, 0.0408 oz.; lead, 18.14%; copper, 1.53%; net selling value per ton, $48.45. Miscellaneous ore: Silver, 30.10 oz.; gold, 0.0321 oz.; lead, 9%; copper, 1.14%; net selling value per ton, $18.33. The receipts for the year from all sources, including $451,319 on hand at the beginning, amounted to $1,228,764; while the disbursements aggregated $923,696, leaving a balance on hand December 31 of $305,057; while the reserve fund contained $8,982 additional. Dividends were paid to the amount of $378,000, making a total since incorporation of $5,877,000. The total earnings during the life of the company has been $11,975,117.

The Yampa smelter, situated in Bingham canyon and operated by the Tintic Mining & Development Co., is operating two reverberatory furnaces and one blast furnace; and a second blast furnace will be blown in within a few days. A third reverberatory is being put in and plans have been made for installing a third blast furnace, which is to be 44 by 300 in. at the tuyeres. It is also given out that a copper converter plant of two stands has been ordered and is to be ready for work in about 90 days. With the present equipment of two blast furnaces and two reverberatories about 650 tons of ore per day can be handled. The ore, which is a chalcopyrite, carrying some gold and silver, is conveyed from the Yampa mine to the smelter over an aerial tramway. The fine ore, which is separated from the coarse by revolving screens, is run through McDougal roasters, of which there are six, with three others to be installed. By this roasting the 30% sulphur is reduced to 5%. Accessory to the system of roasters is a dust chamber 60 ft. long, 30 ft. high, and 18 ft.

wide, connected to a brick stack 120 ft. high. The first reverberatory furnace is 17 by 55 ft. and the second is 17 by 45 ft., there being a separate brick stack for each one. The charge for the reverberatories is made up of the roasted ore and the flue-dust, to which is added some silicious gold ore, the product being 30% copper matte, containing the gold and silver. The slag from the reverberatories runs 38% silica, 42 to 44% iron. The material collected in the dust chamber is worth $70 per day. In the reverberatories it is stated that one ton of coke will produce the necessary heat to smelt four tons of the calcined ore, while in the blast furnaces from 9 to 10% coke is required in the charge. C. W. Saxman is manager of this company, with J. C. Dick as general superintendent, and Frank J. Murphy, superintendent of the smelter.

The Phoenix Mining Co. has just completed a 200-ton concentrating mill on Carr fork, equipped with crusher, rolls, jigs, and tables, to be operated by electric power. This company's property is in the vicinity of the Apex and Yampa mines, and is con-



British Columbia.

siderably developed by adit-levels, opening a lead vein that is 7 to 14 ft. wide. The upper workings disclose carbonate ore and in the lower levels is a fairly clear sulphide. The shipping ore is said to run 35 to 45% lead and 10 oz. silver per ton, while the milling ore will make a 40% lead concentrate when reduced in the ratio of 5 tons into 1 ton. A 2700-ft. cross-cut has been driven to the vein on the mill-level; and there are three adits which follow the vein at higher points, these being 2400, 1800, and 600 ft. long, respectively. H. A. Gephardt is superintendent.

The Bingham-Newhaven Co., managed by C. H. Doolittle, occupies a position on the upper part of Carr fork, above the Highland Boy mine. Work has been in progress here for several years, during which time a dozen adits and cross-cuts have been driven, all but three of which have cut ore. There is a vertical distance of 1200 ft. between the highest and lowest workings. The lowest adit is 200 ft. long and is expected to intersect the vein on its dip, which is to the northwest. The ore uncovered is in the limestone against the quartzite, and carries copper, iron, silver, and gold. A shaft is being sunk at a point in the lowest adit 900 ft. from the portal, where a hoist is stationed, operated by compressed air. The company has a first-class air-compressor plant, electrically operated, and a tramway line from the mine to a connection with the Copper Belt railroad. H. J. Turley is superintendent.

The Utah-Apex Mining Co., managed by R. S. Oliver, is developing its property, which lies adjacent to the Yampa and Utah Consolidated. This is a Boston company whose holdings here comprise an area of 200 acres. Development is sufficient to show valuable bodies of both copper and silver-lead ore. Like other mines on Carr fork, this property is being opened by a series of adits entering the mountainside. A large tonnage of ore is said to have been blocked out.

ROSSLAND, BRITISH COLUMBIA.

Ore Shipments.—Trail and Northport Smelters.—A Tunnel Scheme.—Hall Mine and Smelter.—St. Eugene.

The Consolidated, Le Roi, Le Roi No. 2, and Evening Star mines are maintaining regular shipments, the combined tonnage averaging 5600 tons of ore per week. W. A. Carlyle, consulting engineer for the Le Roi Mining Co., is here from London, and is making a thorough examination of the mine. At the Northport smelter only one furnace (out of six) is in operation; this is treating 200 tons of ore per day. Besides the Le Roi ore, the smelter is treating about 500 tons of custom ore per week. The Consolidated plant at Trail is smelting 5500 tons per week. The receipts of lead ore for January were 3,682,594 lb., more than half of which came from the St. Eugene mine. The next largest shipper is the Vancouver mine in Slocan.

The Granby Co. continues to mine and smelt the regular quantity of ore. Total shipments for January were 74,203 tons, which, at 24 lb. copper per ton, means a production of 1,725,000 lb. of metal. Early in this month a shipment of 400 tons of ore was made from the Snowshoe mine to Trail. This was shipped to fill a special requirement at the smelter. No move has been made to resume work at the Snowshoe or B. C. Copper Co. mines.

Newspapers here are giving considerable space to a proposed tunnel scheme. The idea is to run a tunnel from Greenwood to Phoenix cutting the orebodies of the latter camp at a depth of 2100 ft. The cost is to be $3,000,000 and the Greenwood city council is to give a bonus of $50,000. While the tunnel would no doubt prospect a number of claims along its line, the writer is skeptical as to whether it would pay unless an arrangement is made whereby they would benefit by ore encountered, or unless they became entitled to tunnel-claim rights, as it would not pay to ship Phoenix ore through such a tunnel, under present conditions.

The Hall smelter and the Silver King mine, near Nelson, have passed into the hands of the debenture holders. It is stated that work will be continued actively. This mine was a prime factor in the upbuilding of Nelson and paid well until the ore was lost. Recent work re-opened the orebody, but the company did not have funds to continue development. The smelter, which was built to treat Silver King ore, is out-of-date and was not a success as a custom plant. It will be re-modeled.——The St. Eugene is shipping 325 tons of silver-lead ore to Trail in addition to the quantity concentrated. They are now extracting ore from a body 40 ft. wide and 300 ft. long on the 2000-ft. level. S. G. Blaylock has succeeded the former superintendent, W. P. White. ——At a recent meeting of the Sullivan Co., James Finley was appointed manager and the head office was removed from Spokane to Marysville, where the smelter it situated; this will be more convenient.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The cost of producing one ton of white tin from a cassiterite concentrate containing 70% of the metal is $10 or less.

Fine grinding is essential to high extraction in the cyanide process, but there is an economic point beyond which the grinding must not be carried.

All gelatin dynamites are more difficult to explode than are the ordinary brands, and require quintuple force caps or double strength fuses to develop the full force.

Tool-sharpeners will find it well to keep their slack tub clean. The accumulation of sediment in the tub will cause checking of the drill-steel. Never let anyone pan in the water of your slack tub.

Powder in which nitrate of ammonia has been substituted for a part of the nitroglycerin has a decided advantage in seamy rocks and material which breaks easily, where much of the force of ordinary dynamite would be lost.

Sale of explosives in bad condition is actionable if damage accrues and the merchant knew he was selling powder likely to cause injury and injury actually resulted; otherwise the right of action is limited to recovery for the money paid for the worthless powder.

When blasts fail to explode, do not attempt to drill or bore down to the charge, but clean out the hole to within about 8 in. of it, put in a fresh cartridge or a piece of one, fill up the hole again and fire. This will explode the charge below unless the dynamite is frozen.

Road-work may, under certain conditions, be credited to assessment work on a mining claim. If the road is necessary in order to reach the particular mine, such work may count for assessment; but if it is intended to serve the district generally, then the cost of it cannot be so applied.

In constructing the Simplon tunnel, which extends from Brigue, Switzerland, to Iselle, Italy, a speed of 20 to 22 ft. per 24 hr. was maintained for long periods in a heading 10 ft. by 6 ft.; as a maximum, for a period of a whole month about 765 ft. were extracted. The progress made was remarkable.

The potassium cyanide contained in the discharged residue from a cyanide plant sometimes causes the death of cattle. The trouble may be partly eliminated by fencing the land where the sand settles, but the slime, flowing a long distance, may carry a fatal dose for any animal that drinks in the stream. This may be prevented by placing copperas in the launders carrying the slime to the creek.

The price of antimony ore in California appears very low relative to the market price of the metal. When commercially pure antimony is quoted at 12c. per lb. or $240 per ton of 2000 lb., the ore could be sold in San Francisco for only 60c. per unit; thus, $30 per ton would be paid for ore containing 50% antimony. While the cost of treatment is expensive and the loss during reduction heavy, the chief reason for the low price of ore probably is the fact that the supply is too limited to warrant the erection and continuous operation in California of a properly equipped antimony reduction plant.

Boulders and large blocks of stone are best broken by drilling a one-inch hole into the stone to a depth of 6 to 10 in. A half stick of 60 per cent dynamite exploded in such a drill-hole will break a large boulder. When it is not convenient to drill the rock or there is not time, lay the dynamite on top of the stone and cover it with a shovelful or two of mud or moist earth. As dynamite acts almost exactly like a blow from a hammer, the charge should be placed on the boulder on the spot one would strike if attempting to break the rock with a hammer. Advantage should be taken of any seam or depression there may be in the rock.

On the Rand the tendency for years has been to increase the weight of stamps. The majority of stamps dropping on the Witwatersrand at the present day weigh 1250 lb. each. For several years this was looked upon as a standard weight, but now new mills or additions to existing mills are being erected with heavier stamps. The 300 stamps of the joint Simmer Deep-Jupiter mill will weigh 1700 lb. each. The 20 new stamps for the New Kleinfontein are to weigh 1635 lb., those of the Cinderella Deep 1680 lb., and those of the Wit Deep, 1400 lb. each. At the Luipaardsvlei Estate, Jack East, and joint Knights Deep-Simmer mills stamps weighing 1550 lb. have been in use for a considerable time.

Consumption of Horsepower.—In the Bunker Hill & Sullivan mill at Kellogg, Idaho, there is in use a General Electric Co.'s type L 85-hp. induction motor marked 22.5 amperes, 2080 volts. It has a constant load of 28 vanners, 14 Wilfley tables, three 2-in. centrifugal pumps, and two 6-ft. Huntington mills. Huntington Mill No. 1 crushes a 36-mm. galena concentrate (containing 50% lead) through a 16-mesh diagonal slotted screen, treating 35 tons in 24 hr., with two mullers. This mill uses 9 hp. Huntington Mill No. 2 crushes a 10-mm. middling (siderite) through 12-mesh diagonal slotted screen, treating 100 to 112 tons in 24 hr., with four mullers. This mill uses 16.3 hp. The full load is 64.2 horsepower.

A simple method for the detection of an objectionable quantity of carbon dioxide in the air of mines that has been used by the Inspectors of Mines in the Witwatersrand district of South Africa is the use of a solution of sodium carbonate colored with phenolphthalein. This solution is made on the morning of the day of use by diluting a stock solution consisting of 1 gm. of phenolphthalein and 5.3 gm. of sodium carbonate per litre of water, fifty times with water free from carbon dioxide. The Inspector of Mines is provided with six small bottles (with rubber corks) each containing 10 c.c. of the dilute reagent, and with six bottles of 195 c.c. capacity. By means of a 2-ft. rubber tube the original air is sucked out of one of the large bottles and then the contents of one of the small bottles is emptied into it; the glass stopper is replaced in the sample bottle and it is shaken for two minutes. If the pink color disappear, the air sampled contains more than 1.5 parts per 1000 of carbon dioxide and is, therefore, bad. If there is not sufficient gas present in the air to make the pink color entirely disappear, the proportion may be roughly determined by estimating what fraction of the color has disappeared.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

On Technical Writing.

The Editor:

Sir—The occasional letters and editorials under the caption of 'Technical Writing' are of extreme interest, as they deal with a subject which lies at the very root of technology. While no one can question that there are many men who can do things without being able to write a clear account of how they do it or why, yet no man who has studied the science of his calling and is supposed to be a professional man can be said to have completed his training unless he can clearly explain in writing the how or why of the various phases of his work. The man who cannot give a lucid concise statement on the ordinary topics of his branch of technology can hardly think clearly in an orderly manner, however good a mechanic he may be. When one learns, therefore, that a vast number of technical graduates cannot write an ordinary essay without numerous gross errors, and that there are numbers of engineers that cannot write a lucid report, there is grave reason to question the character of the training that the colleges, responsible for such graduates or engineers, may give.

This much seems apparent. But I do not believe it is the whole truth. There are many men who can dictate a fine piece of letter-writing whose brains appear paralyzed when they get a pen in their hand, and there are others whose thought only seems to flow when they take up a pen or pencil, and who could not dictate a dozen concise grammatical sentences. There are then other elements entering into the question of the expression of one's thoughts than the mere possession of knowledge. Nervousness, lack of appreciation of one's ability to make a clear statement, stage-fright, and modesty all are elements to be considered. Nor is this merely true of writing. It applies with more force to the oral exposition, which may, at times, be as important as the written statement.

An engineer in his time plays many parts. An important part, and one generally overlooked in discussions of this subject, is that as soon as he reaches a position responsible for the success of an engineering work he has first to win the support of others to get means to carry on the work; second, to prevent the opposition party, which nearly always exists, gaining head and stopping work, and third, to gain and hold the loyalty of those associated with him in the practical carrying out of the plans. In doing these things he may have to address meetings in which his every word and action will be noted critically, or write reports and special statements.

The art of expression is therefore of prime importance, and is as essential a part of an engineer's equipment as a working knowledge of trigonometry. For a subject of such wide interest and of such essential a character, it has received but very little attention and even such discussion as you were good enough to initiate in the MINING AND SCIENTIFIC PRESS is meagre and lacks real practical value. It is not enough to point out that we write poor English. That we are all painfully aware of. Who is there who can read a paper of his own after it is put into cold print, when all the errors are past recall, without shuddering at the baldness of his English or without realizing how far short of what he intended the article really is? The crudities stick out all over the pages like sore thumbs. Help in this important branch of engineering training is greatly needed and the PRESS has done a good service in bringing it to the real attention of the profession. Of all the weary stretch of books written to elucidate the art of writing the English language, not one, as far as I know, has ever been written for the need of technologists.

It is a fact worthy of remark that nearly every engineer of reputation writes clearly and forcibly, and not infrequently with a touch of humor and imagiuation that sparkles and illuminates the thought as nothing else could. Whether by instinct or art, the finished engineer usually writes in a style exactly adapted to the occasion. In writing to a stupid board of directors he will use the language and often the forms of diplomacy; to a refractory or willful assistant he will be tactfully forceful; writing for students, a bright style with some touches of fancy all making a helpfully suggestive essay; a paper read to his critical peers giving the result of personal research will be a cold, logical statement of fact redolent of the study, workshop, or laboratory. The popular statement, the essay or article, the pamphlet and book all have their own definite rules of literary expression, and it is to the credit of the engineering profession that its leaders are almost invariably masters of each style.

This is not due to a mere chance, or merely an outcome of the nature of engineering work, although dealing, as the engineer must, with nature in all its manifestations in all parts of the world, he has so many interests that he is usually an omnivorous reader of good books. But frequently he owes his literary ability to painfully slow methods of self study to supplement his early schooling and to supply that which his college, if he ever went to one, miserably failed to give. One will find in nearly every such engineer's library a row of books like 'Slips of Tongue and Pen,' 'Plain English,' 'The Queen's English,' 'The Dean's English,' 'Roget's Thesarus,' Brewer's 'Dictionary of Phrase and Fable,' and so forth. He has imbibed a good deal of this and applied the rules to the peculiar necessities of the engineering literary style. Imagination, without which no man can be great in any phase of life, together with a culture coming from the constant association with able men, and above all with nature, does the rest.

It is readily demonstrable that the mere knowledge of the meaning of words and the rules of syntax are not sufficient for the technical writer. These are too often, like the knowledge of the grammatical rules of a foreign language, never ready when wanted. Practically there can be no question but that the power of writing must be acquired by hard practice, just as we learn to ride or swim. As nearly every man can learn to stick on a horse or keep from drowning for a reasonable time, so all can learn to express their thoughts by pen and tongue, although of course, with different degrees of skill. There is hope for all. It is mainly a matter of practice. Innumerable instances might be given of the development of the art of skillful writing even in unpromising cases; that of Dean Swift—who could not pass his university examinations—to sway an empire by the sole use of his pen in his maturer years, is famous.

The advantage of an able use of the English language being manifest and the possibility of any man of average ability to acquire at least a good working use of it being unquestionable, it is surely pertinent to ask why so many graduates of our technical colleges so generally lack the power of using simple direct English. Undoubtedly one of the main causes is the poor, not to say slipshod and even slangy English used by many professors in their lectures. The evil is accentuated by allowing the students to keep disgracefully poor notes. Of course many lecturers carefully prepare their discourses and critically study the students' notes, but as a rule, the English of the lec-

turer receives very little attention. Poor lecturing and bad note-taking form a very bad foundation for an accurate use of the English language.

Another point in technical training which has received but little attention is the necessity, as it seems to me, of a training in logic. It is greatly to be regretted that no treatise on logic has ever been written suitable to the needs of the engineer. The pious idea that mathematics give all the training needed in this subject by an engineer is utterly fallacious. In the first place mathematics is so poorly taught, as a rule, that even from the mathematical point of view the training is poor; much worse is it, therefore, from the logician's standpoint. Oliver Lodge puts the case excellently well, thus: "The mathematical ignorance of the average educated person has always been complete and shameless, and recently I have become so impressed with the unedifying character of much of the mathematical treatment to which ordinary children are liable to be exposed that I have ceased to wonder at the widespread ignorance." Most engineers, if they are candid, must admit with Trautwine that they "have long since forgotten the little higher mathematics they ever knew," and that "few engineers are good mathematicians." So that, on the evidence of two very distinguished authorities, as a poor substitute for logic we have mathematics, which subject is taught badly and forgotten promptly.

Really good lecturing, careful note-taking, and the introduction of logic as an essential part of a technical training would greatly aid the student in acquiring an accurate use of English. If he cannot have logic, there is no reason why every student cannot have the other two advantages. In this connection the increasing practice of giving students neatly prepared lecture notes ought to be condemned. No student knowing that he will receive a nicely typewritten or printed set of notes is going to keep his own personal lecture notes as carefully as he otherwise would. He thus loses a great educative exercise and loses at the most critical stage of his career a great opportunity of practicing the art of writing, which he so much needs.

As a method of mental training, the writing out of one's experiences and observations is unexcelled. Especially when accuracy of description is the main motive of the student. Accuracy of expression necessarily involves accuracy of knowledge of the meaning of words, and thus by constant practice and effort the student will approach the most perfect of scientific literary styles, namely, that in which the writer cannot be misunderstood. By a little care he will be able to attain accuracy without wrapping his thoughts in ponderous sentences, of which the euphony is entirely destroyed by modifying or restricting sub-sentences. Such a style as that, for example, of Pattison-Muir is to be avoided. On the other hand, a deliberate attempt to copy another's style, or—worse still—to develop a style of one's own, is bound to result in absurdity. Above all, a man should write naturally and as he feels. While, of course, he obeys the fundamental rules of grammar, he will find that he can break with impunity many of the rules of stylists or absurd purists; even to the use of the split infinitive on occasion.

Yet more important than being able to write so as not to be misunderstood is the fact that such a style will also result in the writer clarifying his own thoughts and not misunderstanding the workings of his own brain. Often we approach a subject with confidence that we understand it until we commence to write on it. If a man is honest with his own brain he will many times find that he has only half thought out a subject and that awful gaps exist in his knowledge. Such revelations are of immense help to the engineer who can then quietly strengthen his weak spots before a disastrous professional experience rudely displays them to him.

As stated previously, every form of literary expression is governed by its own rules. Technical writing is no exception. The arrangement of an article for the weekly journal is more or less that of an essay and should be carefully modeled so as to sustain interest. It is frequently polemical and should always be suggestive. To be well constructed such an article must follow a modified classical model. On the other hand, an article may be strictly a record of a technical experiment and should be a cold, logical, impartial statement of fact. The thesis and the scientific or technical book are governed by other laws, and these are modifiable by the nature of the subject or the motive for writing it. Thus we see that no one set of rules can be laid down. This statement is further complicated by the fact that each writer can modify the strict models by his own sense of propriety or taste. Forms and models of mine reports have often been published, and many are truly excellent. To follow these rigorously will result often in a wooden effect and even, in many cases, defeat the object of the report. The fact is, the style of a report is governed largely by the nature of the subject reported upon, and the object of the report. Not infrequently, the character and intelligence of the man for whom the report is made have much to do with the style adopted. A report for a veteran mining man may be written very differently to that for a Chicago business man who seriously believes that a stope-wrench is an essential tool of mining.

It would seem from the foregoing statements that the art of technical writing is a very complicated one. Of course it is not, and it appears so only from the brief presentation given above. It can readily be acquired if the student will commence to study the form of the technical literature he reads as well as the matter. He will thus soon learn to distinguish the better forms from the worse and unconsciously adopt the better forms modified by his own peculiar temperament. As a piece of practical advice, let the student carefully read one journal, instead of hastily skimming many. Let him study the style of the editorials, the staff writings, general contributed articles, and down even to the commercial paragraphs. He will get more technical information and a clearer idea of literary propriety in this way than by the careless reading or rather attempted reading of many journals.

Of course, the hackneyed advice to read good English is sound. Yet I would add, in such reading have the dictionary ever ready to the hand. The many absurdities one often reads would never have been perpetrated if their authors only knew the real meanings of the words they used. Much advice has been given as to the authors to read. My own selection would be Milton's prose writings, as models of form and power of expression; Swift, for clear, logical, and convincing writing; Addison and Goldsmith for elegance and smooth easy diction; and Elia's 'Essays' as models for sustaining interest to the very end, even in trifles. Of all these, Swift is perhaps the best author to read for the technical man; his wonderfully plain, easy, simple style, so logical and exact, is a good model. Anyone who could read an unexpurgated and well annotated edition of 'Gulliver's Travels' without interest is poor timber for the mining engineering profession. The reading of such works as those mentioned above should not be approached as a task but as a diversion from the steady grind at text-books, and as a means of acquiring that easy manner of expression which is the hall-mark of the cultured man of the world. Of course, such a course of reading should not neglect the great moderns, among whom the scien-

tific men, like Huxley, Kelvin, Oliver Lodge, Proctor, and Tyndall, all shine as masters of English. Let Faraday's 'Chemical Manipulation' be read by the chemical and metallurgical student as a model of exposition. For the most simple chemical phenomenon is explained in such lucid English that no student can fail to learn and appreciate the art of full and complete statement.

Practice, and plenty of it, is essential to the acquisition of the art of writing. This the student can always have. He can learn the art of accurate statement by carefully writing up his own laboratory experiments; conciseness, by taking good lecture notes; restraint, by writing for the college publication, where bumptiousness is a cardinal sin; and an easy, natural style by writing full, frequent, and candid letters to his home folk. Conciseness of statement should be steadily aimed at by the student. He will do well always to keep to matters with which he is perfectly familiar. The practice of covering a lack of precise knowledge by writing in glittering generalities is as much a failure in the work-a-day world as it is in the examination room. The advice of the great Duke of Wellington to a young public speaker who wanted to know how to talk so as to have real influence, is as useful to writers as to orators. This was: "Get up. Say what you have to say. Don't quote Latin, and sit down." Which is very good advice to anyone.

A. W. WARWICK.

Choix, Sinaloa, Mexico, September 25.

The El Oro Tube-Mill Lining.

The Editor:

Sir—The large number of claimants of the El Oro tube-mill lining who have recently appeared presents an amusing as well as gratifying commentary on the value of the device. The latest contribution, that of Mr. Arthur De Wint Foote, published in your issue of February 1, and the editorial comment upon it, are the most entertaining dissertations on the subject that have yet appeared. Neither, however, are important, in that they do not seriously touch on the essence of the case.

The points of priority of invention, patenting, and practical application still remain with the writer, since the dates given by the various claimants are antedated even by the date of filing of my application for a U. S. patent, which application was made nearly a year after I had originated the device. In the meantime it was being used and perfected by the El Oro Mining & Railway Co. Dates are not matters of opinion, but of fact readily compared and verified. I conceived the idea of the liner in 1905, and filed application for a U. S. patent on June 13, 1906, which patent, No. 864,357, was issued to me on August 27, 1907. The other much discussed claims have all materialized since the lining was first used at El Oro.

Mr. Foote speaks entertainingly of an old boiler-tube mill which he started to make "about three years ago," which was never used. "During the winter of 1906" he made another lining, but does not narrate the results of operation or whether it was used at all. Mr. Barry of New Zealand invented a lining in which pieces of flinty quartz were "held in cement." Mr. Foote thereupon says of the cast-iron lining used for tube-mills at El Oro: "In many ways it is similar to Barry's." This remark might be equally true of almost all forms of tube-mill lining, which are neeessarily similar in many ways. Mr. Barry's lining, however, omits the essential feature of holding the pebbles frictionally in place. In his lining the flint is cemented in place. In the El Oro lining the pebbles are hammered by each other into the channels, thus automatically forming a flint lining. To accomplish this the channels are wider at the opening than at the bottom. As a pebble becomes fractured or worn and escapes from the channel the vacancy is automatically re-filled by a suitable pebble from the charge. There was no record or patent in existence of this essential feature before I conceived it. Cementing the silex in place is a widely different and vastly inferior method of procedure.

Recently a well known manufacturing company has issued a letter offering for sale a lining "which will accomplish the same end"; this may also be "in many ways similar to Barry's" and yet not possess that feature essential for success which I claim to have discovered, namely, the automatic wedging or holding by frictional contact of a portion of the pebbles of a charge in place to form the grinding surface of the mill, and in this way protecting the iron from wear.

Mr. Hardinge admits that his Mexican patent was issued to him under date of February 22, 1907, so we need not further pursue the inventor of the conical tube-mill.

Mr. C. E. Rhodes' letter in the MINING AND SCIENTIFIC PRESS of December 21, 1907, also states, in addition to what Mr. Foote quotes, that "the rib liner mentioned was invented by J. R. Brown while in the employ of the El Oro Mining & Railway Co." In his letter in *The Engineering and Mining Journal* of December 14, 1907, Mr. Rhodes further states that the lining was used "at the plant of the El Oro Mining & Railway Co. considerably more than two years ago." These statements indicate that the lining was invented by me in 1905, which is confirmed by the date of the filing of my application. During the time the lining was being perfected Mr. Rhodes was cyanide superintendent of the Dos Estrellas Company.

O. Crimmann and R. Riley obtained a Mexican patent dated August 29, 1907, for a lining in which the channels are smaller at the opening than at the bottom. Such an arrangement allows the pebbles to enter the channels where, if held at all, they remain loosely without presenting a fixed grinding surface. It is significant to note that Mr. Riley was foundry foreman at the El Oro Mining & Railway Co. at the time the El Oro lining was developed. His form of lining is copied from one of the earliest linings, which I discarded, finding after experiments that the principle was wrong.

Mr. Foote's admonition to "Render unto Caesar the things which be Caesar's" applies, in my modest opinion, to the equally well known name of the writer. If the lining really was used in Caesar's time, as Mr. Foote intimates, I give up; but if at any time later I claim it. Some time ago I arrived at the decision advocated by you, sir, to "perfect and manufacture the device and show others how to use

it successfully." This I have done by associating with the Blaisdell Company, with whom I am working, with some degree of success, to market and exploit the lining.

It is my desire in this letter to thank my friends who have loyally supported me in this discussion; to assure the mine managers, and others, of my desire to sell to them at a small profit an untainted lining which they may safely buy and use; and to try if possible to lay to rest forevermore the weary wandering ghost of a doubt as to just who is the inventor of the El Oro tube-mill lining.

JOSEPH RODNEY BROWN.

Los Angeles, February 10.

Resue or Dissue.

The Editor:

Sir—In 'Concentrates' of December 21, the term 'resuing' is defined, with the remark that "*resue* is sometimes improperly called *desue*." Surely this statement should be revised if not reversed, for *resue* (whatever its derivation may be) seems to be of very recent, if not spurious, coinage; on the other hand, *dizzue* or *dissue* or *dyzhu* has been used by some of the oldest English writers on mining, and is still current with exactly the same signifieanee which 'Coneentrates' attributes to *resue*. Both the Standard and Century dictionaries inelude *dissue* or *dizzue*, but not *resue*.

S.

Lead, S. D., January 20.

[Our contributor is right. *Dissue* is the older form and we shall be glad to see it in service again; it is good Cornish.—EDITOR.]

Green Gold.

The Editor:

Sir—Referring to the discussion concerning an alloy of gold and silver that has a greenish east or color, I believe that such an alloy has been known to jewelers for many years. I would refer you to Brannt's 'Metallic Alloys,' page 404, paragraph on gold and silver alloys, from whieh I quote as follows: "These alloys are known to jewelers under the names of yellow gold, green gold, and pale gold, according to the proportion of silver."

LOCHIEL M. KING.

San Francisco, February 8.

Pure Cyanide in Silver Plating.—Certain silver platers use only purest potassium cyanide, claiming that an admixture of sodium cyanide is injurious for plating purposes. Commercial cyanide gives an uneven deposit, eauses loeal aetion, and silver is only thoroughly deposited in the immediate vicinity of the anode. A similar faet is true in gold plating, the sodium cyanide causing a difficultly soluble sodium aurous cyanide to deposit on the anode. The average commercial potassium cyanide contains about 20% sodium cyanide; some is almost entirely the sodium salt, while one specimen contained two-thirds sodium chloride.—Metal Industry, Jan., 1903. Abst. in Jour. Amer. Chem. Soc., May, 1903, p. 221.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

In order that a 'grubstake' contract, by which one person agrees to furnish supplies for a prospector and share in any mining claims he may locate, shall constitute a partnership relation, it is necessary that the agreement extend beyond the mere furnishing of supplies and should be in consideration of a participation in any discovery made.

Costello *v.* Scott, (Nev.) 93 Pac. 1, Jan., '08.

A member of a prospecting partnership located certain mining claims and, together with others interested, conveyed a townsite surface right to a third person, in consideration that he perform the location work necessary to hold the claim, and to survey and plat the same. It was held immaterial, as against the partnership, whether such third person did the work himself, or subsequently made arrangements that the work should be done by another.

Costello *v.* Scott, (Nev.) 93 Pac. 1, Jan., '08.

Where a partnership for the location of mining claims was practically without funds necessary to carry on the enterprise, a member of the firm was held to have authority, in good faith, to convey certain townsite surface rights embracing such claim, in consideration that the grantee would perform the location work necessary to hold the claim.

Costello *v.* Scott, (Nev.) 93 Pac. 1, Jan., '08.

Under a constitutional provision requiring the legislature to provide for an eight-hour day for persons employed in mining, or other branch of industry that it may consider injurious to health, it was held that under the police power the legislature alone must regulate the hours of labor, and could not delegate it to either of the co-ordinate departments of the Government.

Burcher *v.* People, (Colo.) 93 Pac. 14, Dec., '07.

Two persons were equal owners of mining claims by virtue and right of discovery and location. One of the owners conveyed a one-fourth interest and the other a three-fourths interest of such claims to a mining corporation; thereafter, under judgment and decree, the mining company re-conveyed to such original owners by separate deeds the same share or interest in the mining claims, that each had theretofore conveyed to it. It was held that the conveyance by such joint owners and the re-conveyance to them did not affect or destroy the original equal ownership in the mining claims.

Ames *v.* Howes, (Idaho) 93 Pac. 35, Dec., '07.

Where coal rights in land assessed in the last quadrennial assessment were sold, it was held that such coal rights could be assessed to the purchaser before the next quadrennial year.

People *v.* O'Gara Coal Co., (Ill.) 83 Northeast 140, Dec., '07.

An employee in a coal mine was directed to mine the coal in a particular manner; the employee, from his experience, knew that the manner of mining the coal as ordered was more dangerous than another method, but proceeded to do so, not relying on the superior judgment of his employer. It was held that he could not recover for an injury on the ground that the employer failed to furnish a reasonably safe place in which to work, but otherwise not being negligent. If, with knowledge of the danger, he proceeded with the work as directed, he assumed the risk ordinarily incident thereto.

ZINC AND LEAD DEPOSITS OF SOUTHWESTERN MISSOURI.

Written for the MINING AND SCIENTIFIC PRESS
By F. LYNWOOD GARRISON.

The zinc and lead mining region that traverses Missouri, Kansas, and Indian Territory is practically contained within the limits of Jasper, Newton, and Lawrence counties, Missouri, the extreme southeastern corner of Cherokee county, Kansas, and the Quapaw Nation, in Oklahoma. In this should be included Baxter Springs, just a little south of the Kansas line, but in the Indian Territory. Although zinc and lead are separately and collectively mined in other parts of Missouri, the tract under consideration is confined to this specific area; it is now and will doubtless continue for many years to be the greatest zinc producing region of the world. The so-called Joplin 'district' is practically confined to Jasper county, a small part of the northern half of Newton county, Missouri, together with Galena in Cherokee county, Kansas; the latter being a relatively limited area. The principal mining towns in this region are Joplin, Webb City, Carterville, Oronogo, Galena, and Baxter Springs. The only mining towns of any considerable importance outside of these limits are Aurora and Stott City in Lawrence county and Granby in Newton county, Mo. The last is one of the oldest, if not the oldest, in the region, and was famous years ago as a lead producer, the zinc ore in early days being considered so worthless as to be thrown on the dump. Many smaller settlements exist throughout the region, which covers an area of over 3000 square miles and has not yet been fully developed. In fact, it is possible, though not probable, that zinc ore may eventually be found upon every square mile of this large territory. Some localities will of course be richer than others, and doubtless a majority of the deposits ultimately developed will not pay to work.

The general geology of the region has been described in the publications of the U. S. Geological Survey, the Geological Surveys of Missouri, Iowa, and Wisconsin, besides a number of independent papers.

This Missouri-Kansas zinc field is contained in a relatively elevated area known to geologists as the Ozark uplift, described by Jenney as nearly quadrilateral in shape, covering the southern half of Missouri and nearly all that portion of Arkansas lying north of the Arkansas and directly west of the Black river, extending for a short distance over the contiguous corners of Indian Territory and Kansas, an area aggregating over 50,000 square miles.[1] The elevation of this area varies from 400 to 2000 ft. above the sea; the central plateau, comprising the greater part of the uplift, having a height of from 300 to 1500 ft. The metal-producing districts are divided roughly in two: the southeast field, comprising the counties of Jefferson, Washington, St. Francis, Ste. Genevieve, and Madison, in Missouri; and the southwestern district, covering the country drained by the tributaries of the Missouri and Mississippi rivers where the States of Missouri, Kansas, and Arkansas, and the Indian Territory corner nearly together.

The country rock of Joplin is a limestone belonging to the Keokuk and Burlington sub-stages of the Lower Carboniferous, or as it has been more recently designated, the Mississippian.[2] This rock was at one time covered by the formation commonly known as the coal measures (Cherokee shales of the Pennsylvanian), consisting of conglomerate, sandstone, and shale interstratified with coal seams. Within the area under consideration these beds have been almost entirely removed by erosion and disruption, leaving here and there small pockets or patches of shale, sandstone, and occasionally a little coal. According to Winslow, these pockets occupy what were originally depressions of circular outline, which are probably sink-holes in the underlying limestone[3]. The beds of the coal measures are sometimes horizontal, undisturbed, and occasionally found capping mounds or hill-tops, but often tilted or broken.

The zinc orebodies found in the limestone occur in, and are intimately associated with, massive tabular and lenticular masses of chert (flint) apparently filling pre-existing cavities, cracks, seams, and fissures in the limestone. This chert may or may not be ore-bearing, but it is invariably associated with the ore and constitutes the bulk of the gangue, though occasionally limestone, sandstone, and even

the black shales, are found with the ore. The chert masses carrying the ore are often of great size—hundreds, even thousands, of feet in length and breadth. The length is much greater than the width since they are usually elongated, though irregular, bodies, known locally as 'runs.' The rough ore is essentially a mass of brecciated chert, the interstices of which are filled with a dark gray or bluish muddy substance derived from the coal shales and sandstones that once overlaid the ore-bearing limestone. The crystals of sphalerite or zinc blende occur in this material. The process of concentration is therefore simple, consisting of a washing or jigging operation by which the heavier particles of blende are separated from the lighter fragments of chert and the mud. This mud is often hardened and toughened by a secondary silicification, which renders the process of concentration more difficult and expensive. The silicification is very pronounced in certain localities, notably at Galena, where the orebody is usually so hard and resisting that little or no timber is required to support sides and roof. The large rounded and more or less angular fragments of country rock frequently accompanying or underlying the ore, are known locally as 'boulders,' and the dark shales found near-by and capping the orebodies are called 'soapstone bars.' They are, of course, not soapstone and bear no mineralogical resemblance to it. Small blocks of this material, as well as a coarse, sometimes micaceous, sandstone are found constituting part of the orebodies or breccia. As a rule, the fragmentary material constituting these bodies is angular and it is seldom water worn, the zinc blende and galena contained in the interspaces being rarely or never diffused through the mass of the material forming the breccia. Red, yellow, brown, black, and white clays are found in all the ore deposits. Generally they are plastic and quite pure, though at times loamy and sandy. In the softer and less consolidated deposits, the clays surround the fragments of chert in the breccia and have ore imbedded in them. According to Winslow, the secondary silicification previously mentioned has been subsequent to the deposition of the blende and the accompanying galena and dolomite.[4] Sometimes the solutions of secondary silica have partially dissolved the original chert and the two forms of silica shade into one another. The silicification that gave rise to the secondary cherts must have taken place at the same time as, or shortly after, the deposition of the ore.

Dolomite, other than the altered limestone, usually occurs associated with the ore deposits; it is composed of a dense mass of coarse white or drab crystals at times constituting a compact rock, but frequently existing as an incoherent soft mass resembling sand. This dolomite as a rule is contiguous to the limestone wall-rock and grows into it. Blocks of limestone are often found covered with a shell of such dolomite, formed, according to Winslow, by the action of solutions containing magnesia upon the limestone.[5] The country limestone itself is rarely dolomitic, but sometimes in the vicinity of the ore deposit it carries some magnesia, probably due to secondary action.

The essence of the question of genesis is whether the metal was derived from sources below or near the surface of the earth. If of subterranean origin, the ore deposits may be expected to extend to an indefinite depth. On the contrary, if superficial and shallow, they will be limited by the extent of the crevices, fissures, and cracks in the limestone, for in such openings alone they are to be found. The theory of deep-seated origin has had within recent years two able champions, the late Posepny and W. P. Jenney. The former was an eminent authority upon questions of economic geology, but he never visited the Joplin region, and obtained his information at second hand. Dr. Jenney, however, spent months, even years, in the region and should know it thoroughly. The theories of these two geologists are also in harmony with those advanced years ago for the upper Mississippi Valley deposits by Featherstonhough, Owen, Percival, and Broadhead.

Their hypotheses may be briefly outlined in a general way as follows: At some distant period in the earth's history, the Carboniferous limestone, together with the underlying sedimentary and crystalline rocks, was disturbed, cracked, and dislocated, either by the natural shrinkage of the earth's crust or by some interior pressure, producing faults and cracks that followed more or less well-defined zones, running northeast-southwest and northwest-southeast. These cracks or fissures extended through the underlying sedimentary and crystalline rocks deep down in the earth. At a subsequent period, probably not distant from the time when the disrupting forces were at work, hot waters under high pressure and bearing the metals in solution, ascended through the openings from the interior. Upon coming in contact with the carbonaceous materials of the lower Coal Measures or some other suitable precipitating agency, or else by a relaxation of pressure, a chemical reaction took place and the metals were deposited in these cavities and crevices in the form of sulphides of zinc, iron, and lead.

With the exception of Percival, the older geologists referred to the subject in a very general way and seemed satisfied to dismiss it with a few words, attempting no elucidation of such an obviously important, though obscure, matter. We must bear in mind, however, that the science of geology in general and that of economic geology in particular was in a very crude state forty or fifty years ago. Furthermore, the country in question was then practically a wilderness not thoroughly known even in a geographical sense.

Featherstonhough, arguing from the presence of red clay in the superficial lead deposits of southeastern Missouri, says, "All these circumstances seem to point to the projection of this metallic and mineral matter from below."[6] Owen's views were based upon general considerations, and are decidedly vague. He expressed his belief in the deriva-

tion of the ores from beneath and implied they were in some way due to the fact that they are "based upon a syenitic and granitic platform lying somewhere between one thousand and two thousand feet below."[7]

Percival's studies appear to have been confined to the lead and zinc deposits of southwestern Wisconsin. In a general way the same geological facts apply to all the numerous and extensive lead and zinc deposits of the Mississippi Valley. Percival was most impressed by the evidence of fissures, faults, and dislocations in the ore-bearing region he examined and their probable bearing upon the deposits, for he says: "The opinion expressed in my former report that the mineral was derived from beneath, is strengthened not only by the general results of my observations in the diggings, but by the appearance of disturbance in the strata, particularly along the line of the great body of mineral traversing the middle of the district, and by the relation in the bearing of that body to the extensive ranges of primary and metamorphic rocks toward the northeast, indicating that the mineral may have arisen from a mass of such rocks beneath the secondary strata."[8]

Posepny, in his excellent monograph upon the 'Genesis of Ore Deposits,' draws his deductions from what he saw at the only deposit he visited in Missouri, if not in the whole Mississippi Valley, the Mine La Motte in Madison county.[9] He thinks it inconceivable that such deposits, consisting wholly of sulphides, could have any other than a subterranean origin. Referring more particularly to the Wisconsin zinc and lead, he finds the great thickness of limestone and sandstones underlying the productive horizons not a conclusive argument against their deep-seated origin, and suggests that the solution may have effected an upward passage through the sandstone of a distant point not yet exposed.

Jenney claims to be able to recognize systems of fault that cross each other in different directions and which serve as channels for the up-flowing of metallic solutions from below. He says: "Faulting and disturbance of the strata are the controlling factors influencing the localization of the lead and zinc ores throughout the Mississippi

One of the New Districts Southwest of Joplin.

Valley. This is true as well for all metalliferous formations in all the mining regions of the globe, so that the law may be stated as universal, that all workable deposits of ore occur in direct association with faulting fissures traversing the strata, and with zones or beds of crushed and brecciated rock, produced by movements of disturbance. The undisturbed rocks are everywhere barren of ore."[10] While this general law may be accepted, with exceptions, it does not follow that when orebodies are found in faults, fissures, and disturbed strata, they must necessarily be derived from below. If in one instance such disturbances provided receptacles for the deposition of the ore when derived from subterranean depths, they would in another case be equally available when these sources were closed by underlying impervious rocks and the metallic solutions came from above. It must be clear, therefore, that the mere existence of faults and disturbed zones, such as are found but to a relatively slight extent in the Joplin region, is not a conclusive evidence of the derivation of the orebodies from below.

Jenney contends there are no evidences of the formation of lead and zinc ores taking place in the mines at the present day, hence he concludes that the deposition of the ores has long since ceased, and that it must have occurred at a definite period when the subterranean circulation of waters in the strata and the conditions influencing and affecting the formation of the orebodies were radically different from those now existing. While it is reasonably certain that the conditions are now different, it is doubtful if we have a right to assume that the deposition of sulphide ores has ceased, for I have frequently seen abandoned tools taken from old workings at Joplin and Galena more or less completely covered with crystals of blende.

According to C. R. Keyes, recently State Geologist of Missouri, the zinc ores are found in all the geological formations from the Second Magnesian limestone through to the Upper Burlington, but they are not equally distributed. Only four productive horizons for lead and zinc are recognized, and they are the Upper Burlington limestone, the Hannibal shale, the First Magnesian and the Second Magnesian limestones, their relative productiveness being in the order named. All the other horizons are virtually barren.[11] He states his belief that the ore and gangue that fill the fissures have come from below in solution in hot alkaline waters. The more open and porous the rocks through which they pass, the larger and richer the orebodies; consequently, the harder and more compact the formation, the poorer or smaller the mineral deposit. Thus the great breadth of the orebodies and their remarkable richness in the Upper Burlington limestone is accounted for by the porous nature of the rock and the readiness with which water enters the cavities in it. The various heavy 'runs' of mineral in this formation are contained in shaley and more porous layers. In striking contrast to the rich deposits of the Upper Burlington is the barrenness, in this area, of the Lower Burlington, which immediately underlies it. In the latter formation are found all of the most unfavorable conditions for the accumulation of an orebody. The hardness and compactness, both of the limestone and chert, have made it impossible for the ore-bearing solutions to penetrate more than a very little beyond the limiting walls of the original crevice.

(TO BE CONTINUED.)

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

NOTICE.—Owing to the large number of specimens forwarded to this department, it has been found necessary to make a charge of 25 cents (to subscribers) for each determination, in future.

A specimen of olivine diabase was received from A. M. W., of Amador City.

A piece of pyritiferous shale of no value was sent by J. P. M., of Basslung, Washington.

A piece of volcanic breccia stained by hematite came from Rosebud, Nev., marked A. S.

The oxides of manganese, pyrolusite, and psilomelane came from Big Oak Flat, Cal., marked L. F.

The specimen of quartz sent by M. F. B., of Boston, Mass., contains pyrite, galena, and gray tetrahedrite.

The specimen from H. C., San Francisco, is opal with red cinnabar and small radiating needles of millerite.

Specimens from Santa Barbara marked S. C., are: No. 1, biotite-gneiss; No. 2, schist with pyrite; No. 3, volcanic tuh.

Specimens from Jerome, Ariz., marked A. G., are: No. 1, banded jasper; No. 2, chloritic gneiss; No. 3, diorite; No. 4, serpentinized rock containing pyrite.

The specimens from Cannonville, Utah, marked C. C. W., are: No. 1, mineral resin; No. 2, oil shale. Their value can be determined only by a field examination.

L. H. G., of Berkeley, sends: No. 1, andesite; No. 2, quartzite; No. 3, granite; No. 4, slate; No. 5, limonite and calcite; No. 6, quartzite; No. 7, altered rock containing pyrite; No. 8, quartz-porphyry.

D. C. F., of Tonopah, sends minute crystals of colorless fluorite with the rare combination of forms, octahedran (111), cube (100), rhombic dodecahedron (110), trapezohedron (311), tetrahexahedron (10.3.0), and hexocathedron (10.4.3).

The samples from Callahan, Cal., marked A. F. S., are: No. 1, black manganese dioxide, psilomelane; No. 2, sphalerite in quartz; No. 3, cerussite; No. 4, galena, chalcocite, malachite, and azurite in quartz; No. 5, pyrrhotite and pyrite; No. 6, galena and sphalerite; No. 7, stibnite and pyrite; No. 8, arsenopyrite.

E. D., of Kimberley, Utah, sends a specimen of quartz containing a black alteration material, now manganese dioxide.

The Historical Development of Colorado Viewed From a Geological Standpoint.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

In the mining of the precious metals, Colorado holds the first place among the States of the American union. It is situated so as to cover a large portion of the continental range, which, under the name of the Rocky Mountains and the Andes, stretches through the Americas from Alaska to Patagonia. The Rocky Mountains extend through Colorado from north to south, a distance of 280 miles, between the parallels of 37° and 41° north latitude. This mountain range, which loses its boldness in Wyoming, to the north, and in New Mexico, to the south, culminates within Colorado in a great number of snowclad peaks, of approximately equal altitude, ranging between 14,000 and 14,500 ft. above sea level, the loftiest crest being that of Sierra Blanca, in the Sangre de Cristo range, which attains a height of 14,464 ft. The mines are situated for the most part, between 8000 and 12,000 ft. No precious-metal mines are at a lesser altitude than 7000 ft. The highest mine is, probably, the Present Help, on Mount Lincoln, at 14,202 feet.

A portion of Colorado belonged to Mexico until 1848. The first discovery of gold was made in the summer of 1849, but actual mining did not begin until 1859. Silver ores were recognized shortly afterward. At the end of 1907, the total production of gold in Colorado is estimated to have been worth $400,000,000, and that of silver had an exactly equal value. These figures are eloquent of the growth of the great industry from humble beginnings. It covers, historically, only a brief space of time, but development has trodden so fast upon the heels of discovery that the achievement has been possible within the life of one of the generations of man.

The discovery of the mineral deposits was associatel successively with different geological formations, the prevalence of ore in any particular rock inciting the search for gold and silver in similar rocks elsewhere in the adjoining mountains. Hence the history of the development of Colorado's mines includes the story of the gradual recognition of a succession of ore-bearing terrains.

Mining in this region may be considered to have had its beginning when John Gregory, at Blackhawk, in the Gilpin district, discovered the lode that still bears his name. This occurred on May 6, 1859. The lode traversed the granitoid gneiss of the Front range, which, flanked by battlemented cliffs of later sedimentaries, rises boldly above the dreary level of the great plains. These Archean rocks were the scene of the earliest mining activity, on account of their accessibility from the prairies and the fact that their weathered surfaces exhibited numerous outcrops of iron-stained veinstone. As the same formation occurs in the adjoining counties, it is not remarkable that the development of the Boulder and Clear Creek districts was contemporaneous with that of Gilpin.

The gorges of the mountain torrents afforded natural lines of advance to the army of prospectors. One party went up the river Platte, from its gateway through the range, and then, crossing over into the upper valley of the Arkansas, they found gold-bearing gravel in the bed of a tributary stream, which became known as California gulch. This was on April 8, 1860. One of the pioneers who participated in this event told me that he and his comrades found fragments of porphyry in the first gravel they tested. This they accounted a favorable sign, no less than the actual particles of gold, because it reminded them of similar conditions observed by them on the Feather river, in California, where they had been working previously. Little did they guess the significance which the porphyry would have in future years on account of the enormous wealth that this rock covered on the adjacent hills. The placer diggings of California gulch proved extremely rich. In the sluice-boxes pieces of silver ore were found. This led to prospecting on the hillsides above the diggings. Carbonate of lead, in the form of crystalline cerussite, was encountered amid the drift that covered the true rock surface of, what is now called, Dome hill. As a consequence of this discovery, a shallow shaft was sunk. A lode formation of silver-bearing lead ore was found outcropping under the drift. Thus was Leadville born. This occurred in the autumn of 1875. In 1887 the annual output of the district culminated in a production of silver ore valued at $13,500,000.

The ore deposits of Leadville were found to lie along the contact of limestone and porphyry. The limestone proved to be of Lower Carboniferous age and the porphyry, under the microscope, was recognized as quartz-felsite. Ore-measures of enormous extent were traced along this horizon and, as a consequence, the prospector commenced an active search for similar conditions elswhere. This led, in July, 1879, to the discovery of silver-lead ore in the same geological horizon on West Aspen mountain in the Roaring Fork district, which has since become identified with the town of Aspen. No rich orebodies were, however, uncovered at that date and the mining camp of Aspen did not rise into prominence until ten years later. In 1892 the output for twelve months reached 8,256,467 oz. of silver. During this period several parties of prospectors crossed the complex of mountain ranges occupying the southwestern corner of Colorado, and found other rich deposits of ore, also in Carboniferous limestones, where the Dolores river had cut through them. This was in 1878. A rush set in with the cry that "another Leadville" had been found at Rico. The expectation proved to be premature. It was not until October 8, 1887, that the first rich ore-mass in this locality was found on Newman hill and forthwith made Rico an important mining district.

Thus Leadville, Aspen, and Rico are linked by a similarity of geological conditions leading to a successive mining development.

Among the pioneers who crossed the San Juan mountains, to discover the ores of Rico, were sev-

eral who had previously opened up gold and silver veins in the eruptive rocks of the upper valley of the Animas river, near Silverton. From that mining camp exploring parties scattered up the tributary streams. Some of them ascended Mineral creek and crossed the divide into the watershed of the San Miguel river, where gold placers were found, and worked, in 1874. This led to the discovery, on the high range at the head of the valley, of several very persistent lodes, carrying both gold and silver and traversing a volcanic breccia. The district named Telluride thus came into existence and in 1882, by the uncovering of the Yankee Girl lode, on the other side of the range, the Red Mountain district attained prominence. The characteristic rock of these districts is an andesite breccia of early Tertiary age; it is a geological formation that has played a leading part in the history of Colorado ever since the day, in 1875, when the Sheridan vein was discovered above Telluride. This volcanic breccia caps the high ranges of the whole San Juan region, covering an area of about 8000 square miles, and consequently, the development of the two districts already mentioned was soon followed by an outbreak of mining activity upon the mountains overlooking Ouray and Ophir, as well as among all the snowclad hills that guard the source of the Gunnison and Uncompahgre rivers.

It may seem strange that the knowledge of these facts did not lead to the earlier discovery of Cripple Creek, which is likewise in an andesite breccia of early Tertiary age. This is an interesting point. The only complete geological maps of Colorado in existence are those based on the reconnaissance surveys of Hayden. They were published in 1874. Since then the United States Geological Survey has issued accurate geological maps of certain important mining districts, but these cover only selected localities covering restricted areas, so that there is no approach as yet to a complete map of Colorado. Of the Hayden maps one can only say that, considering the necessarily hasty character of the explorations on which they were founded, they are surprisingly good. They exhibit, of course, many errors of detail, but they served more than twenty-five years ago, to give, to those whom it concerned, a comprehensive view of the general geology of a complicated mountain region. On these maps the eruptives that cover the San Juan highlands are clearly shown and large patches of similar rock are marked as occurring in various parts of the State; among others there is a distinct heart-shaped area of Tertiary eruptives set down as occurring amid the granite of Pike's Peak and immediately to the south of it. That patch of Tertiary eruptive is now the Cripple Creek district.

To Pike's Peak clings the romance of the first gold excitement. It was this old beacon mountain that guided the emigrant caravans across the trackless prairie over forty-five years ago. Although no gold-veins were discovered, at that time, on the mountain itself or on the smaller hills that cluster about the central mass of pink granite, yet, the motto, "Pike's Peak or bust," written on the canvas of many a pioneer's wagon, has gone down in history as an expression of the mock-heroic spirit of those argonauts of 1859. That no gold was found in this region in the early days was due to the fact that the mass of Pike's Peak itself does not, as far as is known, even to this day, carry any valuable veins of ore, while the eruptive rocks that cover its southern approaches are shattered at surface and therefore appear as rounded grass-covered hills, which served as an excellent pasture for cattle up to the time when they were uptorn by the mining activity of a more recent period. This shattering of the superficial rock, due mainly to the action of frost at a high altitude, affected the veins also, for they are, for the most part, simply bands of fractured rock impregnated with gold. They shared the fissile character of the country and, consequently, its degradation also. The absence of outcrops is the chief reason why Cripple Creek remained so long undiscovered.

Creede and Cripple Creek were contemporaneous. Creede is on the eastern edge of the San Juan region, and in 1892, it sprang into tremendous activity, consequent upon the uncovering of several bold outcrops of silver ore in an agatized veinstone, which followed well developed fractures through a sheeted eruptive. Silver mining was the most important industry in Colorado sixteen years ago, therefore Creede was more popular than Cripple Creek. At that time the market price of silver afforded large profits to the mine owners and the search for it attracted the enterprising to an unusual degree.

In the spring of 1891 the Cripple Creek district came into existence as the result of the discovery of gold ore on a cattle range that covered the southern slope of Pike's Peak. The first finds were of no great moment. The district had been the scene of a disappointment seven years earlier, when a short-lived mining excitement had been created by false statements. Furthermore, as already stated, Creede and silver mining were in fashion and certainly offered more attractions than a discredited region over which several waves of exploration had swept in vain. Therefore, it was not until 1893, when the closing of the Indian mints caused a collapse in the price of silver and prostrated, for a time, the mining of that metal, that the energy of Colorado turned to Cripple Creek. The new district responded to the harrassing needs of a great financial crises. In 1894 the production was $3,900,000; in the following year it rose to $7,800,000, and in 1900 it culminated in an output of $18,147,681.

The old rallying call of the pioneers of 1859 was vindicated and Pike's Peak, which was once a beacon to guide the gold-seeker from the East, became destined to throw his protecting shadow over the greatest gold-mining area in Colorado. Thus has geology been woven into history and thus were the uncertain steps of a young industry upheld by two fairy godfathers—fortune and science.

An important event in 1907 was the opening up of a new source of iron ore supply at Mayari, Cuba.

Sunlight and Shadow on Dolores Mtn., at Rico, Colorado. Newman Hill and Enterprise Mine in the Middle Distance.

Victor, in the Cripple Creek District, Colorado.

MINING REGULATIONS IN CHINA.

In the Anglo-Chinese commercial treaty of 1903, the Chinese government agreed to revise the mining regulations then in force, in such a way that foreign capital could be employed under more favorable conditions. The first set of regulations submitted were so unsatisfactory that they had to be withdrawn. During the autumn of 1907 a second set was submitted to the Wai-Wu-Pu and were approved by the throne. These also are so ambiguous, conflicting, and full of restrictions as to offer endless opportunity for controversy, and it is not likely that they will be approved by the powers concerned. It may be of some interest, however, to outline their general features, in order to show what the sentiment of the Chinese government is in regard to such enterprises.

The regulations provide that control of all mining operations throughout the Empire shall be placed in the hands of the Board of Commerce and Agriculture. In each province a mining office is to be opened, under the control of a mining deputy, who must be a Chinese, although he may employ foreign experts. This office has entire control of all mining operations throughout that province. Before any prospecting work can be done, application must be made to the proper mining office for a permit, stating the locality to be prospected and the mineral sought. After investigation, a permit will be issued by the head office; this is good for one year, but may be extended for six months more in case the company has proceeded in the work with diligence and still requires more time. The area covered by a permit may not be greater than 30 *li*, and must be wholly within one district. After prospecting has proceeded to a depth of 30 ft., a mining permit must be secured from the head office. To obtain this, application must be made, stating the details of the partnership under which it is proposed to work, together with a security of 1000 *taels*,* and the name of some well-known firm as a business reference. The area covered by a mining permit is 300 ft. square, but the same company can apply for more than one, up to a total of 160 acres. No mine can be operated without Chinese partners, but where no Chinese wishes to invest capital in working, there may be an entirely foreign operating company, the holding company consisting of Chinese and foreigners.

The fees required to be paid are a ground rent for the land, a tax on the monthly output, and a further bonus upon the output from land owned by the Government. The tax on output is 1 *mace* (about 7 cents gold) per ton for coal and iron ore. On gold and silver ores it is either 5 or 10% of the value, and for tin and copper ores, 3%, while on jade and precious stones it is 10%. The land rental also varies according to the character of the mineral. In the case of government-owned land one-half of the profits of working must be paid to the Government. It is specified that where the Chinese owner does not wish to share in the risk of mining, he may accept a yearly rental for the use of his land, but in all such cases three-tenths of the shares of the operating company must be held in reserve for a period of five years, to give opportunity for Chinese to become partners in the enterprise, if they may later wish to do so.

The regulations further provide for the periodical submission of plans of the workings to the mining office, monthly reports, and the inspection of the books and records of the company. Various miscellaneous questions of public policy are further provided, some of which, if adhered to, would be almost prohibitive. For example, it is specified that mining may not be carried on within three *li* of any important waterway, road, or railway. No mine may be opened within 3 *li* of the grave of any important person, nor within 500 ft. of the grave of any person. Altogether, the regulations, if agreed to and carried out, are well calculated to discourage the use of foreign capital in mining work.

*A *tael* is $1\frac{1}{3}$ oz. avoirdupois; 1 *tael* is equal to 10 *mace*. A *li* is about a third of a mile.

Rules for Employees at Goldfield.—The Goldfield Mine Owners' Association has formulated the following rules and regulations:

This mine is to be worked under the open-shop policy of the Goldfield Mine Operators' Association, hiring and discharging men without regard to whether they do or do not belong to any labor organization, and under the following rules and regulations:

1. The time of each man on every shift belongs to this company and to no one else.

2. No walking delegate or other representative of any labor organization is to be allowed upon these premises at any time or for any purpose.

3. No soliciting of membership in any labor organization is to be allowed upon these premises at any time by an employee of this company or by any one else.

4. No discussion of labor questions, either for or against unions, or in any way connected therewith, is to be allowed during working hours, or upon these premises at any time or under any circumstances.

5. No employee of this company is to be annoyed or interfered with by any other employee in his work in any way whatsoever because he may or may not belong to any labor organization, or for any other reason, and all employees are to work together harmoniously for the best interests of the company.

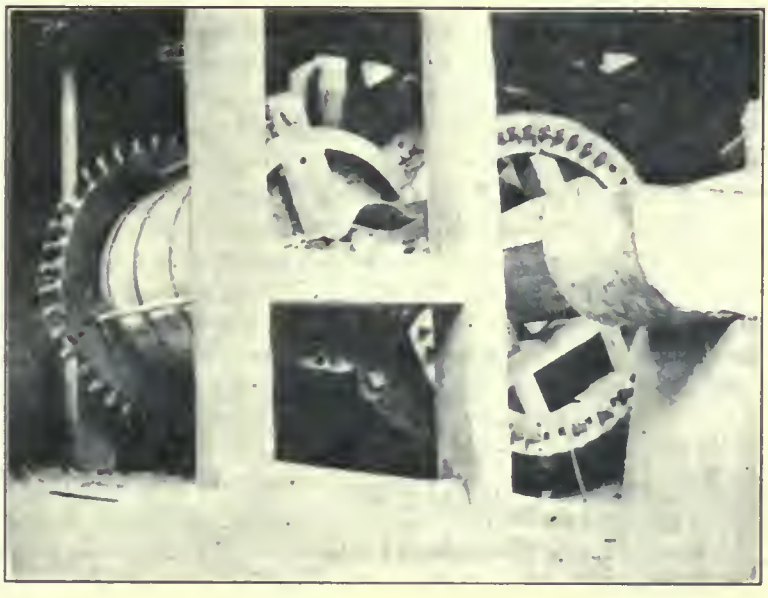
6. No employee of this company is to harass, intimidate, or interfere with any working man of the Goldfield mining district because he does or does not belong to any labor organiation.

7. All employees are requested to report any violations of these regulations to the management, and any employee found guilty of violating them, or any part of them, will be immediately discharged and be disqualified from any further employment by this company.

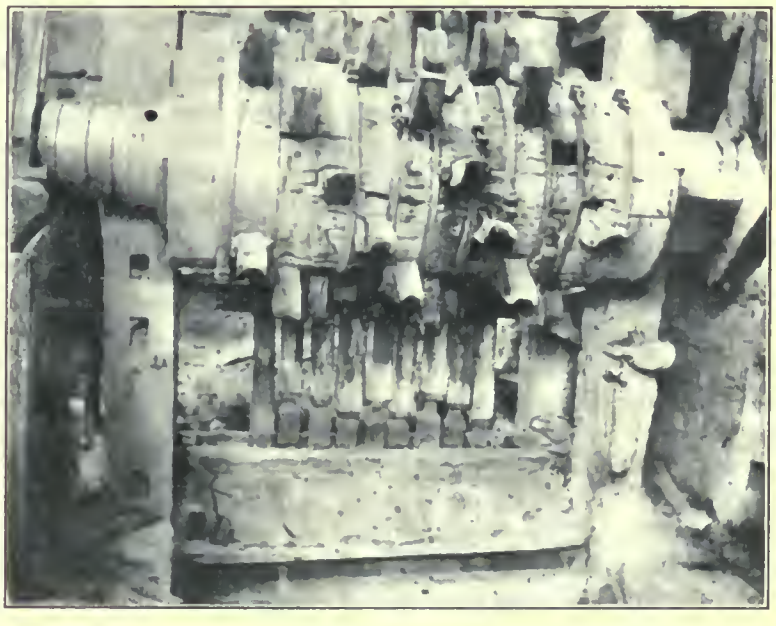
8. Any outsider violating any of these rules will be immediately ejected from the premises and prosecuted by law for trespass.

OLD WAYS.

The accompanying illustrations show one of those old Mexican mills that, by force of contrast with a modern plant, mark the progress made during the last fifty years. For the photographs we are indebted to Mr. Alfred F. Main, of El Oro, and for the few descriptive notes to Mr. Constantine G. Rickards, the owner of the property on which the old mill stands. It is in Oaxaca. The ten stamps are of wood, shod with iron. With the exception of the shoes, all other parts—such as cams, tappets, shafts—are of wood, and connected directly to a wooden water-wheel 18 ft. in diameter. Even the driving gear of the amalgamating barrel and the cam shaft are of wood. The cam shaft is lubricated in its bearings with a stream of water. After being pulverized, the ore goes for treatment by the Patio process. About 50 tons of finely pulverized ore are laid out on a floor and mixed with water to a suitable consistence. The resulting pulp is then well mixed with from 2 to 4% salt, the mass being left untouched for a period in order to admit of the solution of salt and the decomposition of the ore. Subsequently to this, the cake or *torta* is trodden by means of horses, so as to expose it to the air. A small percentage of copper sulphate, which has the effect of assisting the process, is added, after a proper proportion of quicksilver has been strained through canvas over the mass. This process occupies from 20 to 30 days, the mass of pulp or *torta* being continually trampled by horses and turned over by spades, a number of samples being taken daily and washed in a small earthenware dish, in order to ascertain the condition of the amalgam, an experience only to be acquired by considerable practice. As soon as the silver is found to be sufficiently amalgamated, the whole mass is submitted to a washing process, by means of which the amalgam and waste material is separated. The amalgam is then squeezed through canvas bags, in order to remove the excess of quicksilver, subsequently retorted, conveyed to a small Spanish reverberatory furnace and run into bars.



Wooden Gear.



An Old Stamp-Mill in Oaxaca.

GAS ENGINES RUN BY GASES FROM COPPER FURNACES.

The Mansfield company of Germany has for some time past been utilizing the blast-furnace gases from the copper furnaces at the Krughütte works for direct consumption in gas engines. The blast-furnace gas has a heating power of 650 calories per cu. m.—the proportion of carbon monoxide being 21.65%—and as the volume of gas amounts to about 21,000 cu. m. per hr. the available power from this source, when used in gas-engines, is between 4400 and 4500 hp. Owing to the lessened output when any of the furnaces have to be cleaned and also owing to variations in the calorific power of the gas, the mean of 2700 hp. is all that can be depended upon. The furnaces are connected up to two gas-mains—one about 62 in. diam., the other 39½ in.—either of which can be disconnected for cleaning or repairs. Before reaching the engines the gas has to be freed from dust, for which purpose it is passed through counter-current washers; these consist of spiral blades, rotating at a peripheral velocity of about 165 ft. per sec. In passing through the apparatus the gas is brought into intimate contact with water, which is sprayed by the action of the blades and forced in the opposite direction to the flow of gas. After being dried, the gas, which now contains only about 0.003 gm. of dust per cu. m., against 17 gm. in its original condition, is led to a gas-holder capable of storing 18,000 cu. ft., whence it passes to the engines. These are two in number, each of 1300 hp., a third engine of equal capacity being in course of erection. Each motor is of the two-cylinder class, with fly-wheel mounted on a common shaft between the halves, and each develops 1300 hp. when running at 125 revolutions and driven by gas of the above-mentioned calorific power. The cylinders are water-cooled, the effluent water being pumped up into a cooling tower and thence returned to the supply tanks. The fly-wheels constitute the rotors of the three-phase Siemens-Schuckert generators, developing 1080 kw. at 3000 volts tension.—*The Mining Journal.*

HANG FIRE.

By William Maurice.

*In view of the fact that four pit sinkers are reported to have been injured at a Sunderland colliery so recently as October 24 owing to the unexpected explosion of a blasting charge, it may prove of some service to the mining community to point out that electric detonators can and do at times hang fire. Under the Quarries Act, "If a shot has apparently missed fire, no person shall be allowed to go near it until after the lapse of half an hour, except where electricity has been used," and in coal mines an electrical miss-fire is exempted from the regulation as to fixing of caution boards or fences. It cannot, therefore, be too well known that such regulations are misleading and liable to cause accidents. In the case referred to, it would appear that the explosion was due to a simple miss-fire and subsequent detonation by a blow from a pick, though the report calls it a "serious hang-fire."

It is not unusual for one in a group of simultaneously fired shots to miss, and consequently there is always an element of danger in group-firing. Probably a nearer approximation to perfect safety would lie in the use of electrically ignited time fuses, though it must also be admitted that the use of a suitable detonator would go a long way toward ensuring the simultaneous ignition of any number of shots. Hang-fire, or retarded ignition, may occur in the electric detonator or it may occur in the explosive. A damp detonator might readily hang fire.

It is well known that a shot will sometimes explode after prolonged turning of the exploder handle, whereas in general less than half a turn will suffice. The retardation might be caused by increased resistance in the circuit through broken wires, bad joints, or grease or dirt on spring contacts and terminals, permitting the passage of only just sufficient electrical energy to warm the fuse bridge. The latter has then to be kept heated during several seconds before the temperature rises to the point of ignition of the priming. The same effect would be produced if the exploder were under-powered, owing, for instance, to loss of magnetism. Or delayed ignition might be caused by defects in the fuse, such as badly mixed, damp, or insufficient priming, or by a wet charge.

Capt. Desborough states that he had electrical hang-fires when firing experimental shots with three different ammonium-nitrate explosives, that of greatest duration involving an interval of about 50 seconds between the explosion of the detonator and the explosion of the charge. With all these explosives he subsequently had several miss-fires, and in each case, when the charge was extracted, he found that the detonator had fired, but had failed to explode the charge. The difficulty was overcome when a stronger detonator was employed. In this connection Capt. Desborough mentioned that a cartridge of carbonite was found to be burning in a shot-hole in a colliery in South Wales. This was by no means the first instance of the kind, and the cause seemed to lie in the use of a faulty or insufficiently powerful detonator.

The Annual Report of the Inspectors of Explosives for 1906 also records three cases in which a hang-fire has occurred with electric firing. In one of these cases two attempts were made to fire a shot electrically (high tension); the cable was then disconnected from the detonator leads and tested. It was found to be all right. The shot then exploded. There is practically no doubt, says the report, that this was a case of hang-fire. The time elapsing between the disconnection of the cable and the explosion of the charge was about five minutes.

Dynamite, guncotton, nitrate of ammonia, and other blasting materials containing nitrates, decompose gradually in the air, and give out nitric oxide, but if they are ignited in a closed space they instantly decompose, without forming a trace of nitric oxide. The first slow process changes immediately into the second if the free evolution of gas be hindered and the pressure raised. The reaction produced by a detonator is the same as that by ignition in a closed space at high pressure. Both are so rapid that the whole of the charge is at once converted into gas. But if the ignition be defective, the charge may ignite and burn instead of exploding; it is then said to 'cook,' and gives off nitric oxide. The explosive power of a charge also varies with its composition, and depends, in grisounite, upon the small quantity of nitro-napthalin that it contains. If the charge begins to burn, the increasing pressure caused by the gases given off may produce an explosion and ignite the cartridges one after the other.

*Abstracted from *The Quarry*.

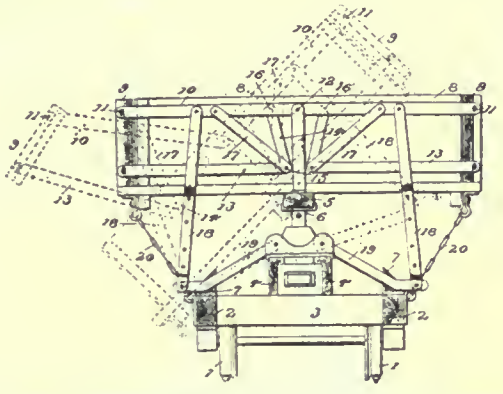
Tantalite in Australia.—In the Wodgina district in Western Australia a tantalite-bearing dike of pegmatite has been found near McCarthy's creek. In places the dike is almost entirely composed of the soda feldspar albite, while elsewhere it is very largely quartz. Tantalite is very freely visible in the albite, in coarse pieces, often many pounds in weight. By ground-sluicing below the dike some heavy lumps have been obtained, one weighing about 500 lb., evidently derived from the weathering-down of the pegmatite. The quantity of tantalite produced by the placer mining is 34.1 tons. The mines were worked energetically for a short time until the consumers' stocks were filled and then the mineral could not be sold. The industrial uses of tantalite are at present very limited and the demand for the mineral small.

Uses of Ground Mica.—Ground mica is used in somewhat increased quantities, the coarser grades in mica bronzes and paints, and also as an absorbent for explosives. Ground mica also forms an ingredient in some heavy lubricants. The finest ground mica, or mica flour, finds a considerable market with the manufacturers of high-grade wall paper, the lustre obtained by the use of the muscovite dust having the advantage of both permanency and brilliancy. Specked mica is seldom used for grinding where a good grade of ground mica is desired, since it spoils the color and quality of the latter.

MINING AND METALLURGICAL PATENTS.

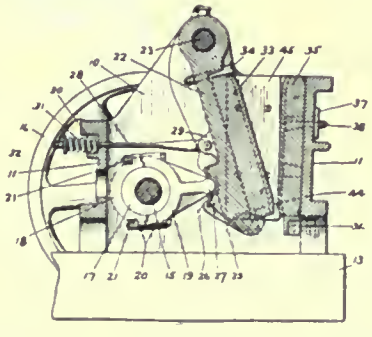
Specially Reported for the MINING AND SCIENTIFIC PRESS.

DUMP-CAR.—No. 874,519. Edward S. Maclin, Knoxville, Tennessee.



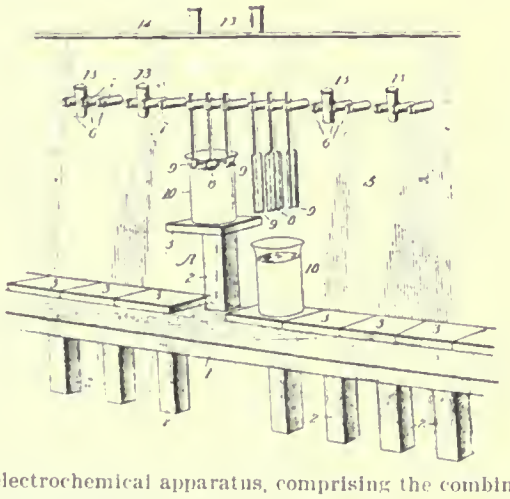
In a dump-car or similar structure, the combination of a car-body having a displaceable wall, a toggle connecting said wall and a relatively fixed part of the body, and a link connected to said toggle to forcibly spread the same upon dumping of the car.

ROCK-CRUSHER.—No. 873,081. Edwin S. Phillips, Kennett Square, Pennsylvania.



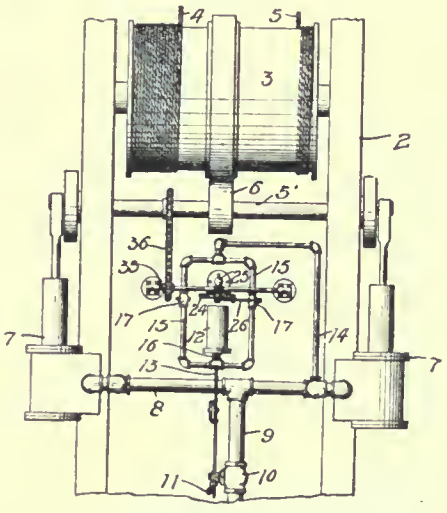
In a rock-crusher, the combination with the moving jaw and a shaft from which the same is pendulous, and the fixed jaw, of the main shaft, a cam thereon, a strap on the cam having a removable section and a toggle on the removable section of the strap, said toggle having a rounded head, there being a cup-shaped recess in the moving jaw, and a wearing plate of substantially uniform thickness having its central part dished in to conform on one side to said recess and on the other side to the rounded head of the toggle.

APPARATUS FOR ELECTRO-CHEMICAL ANALYSIS.—No. 870,674. George A. Guess, Silverton, Colo., and Herbert E. T. Haultain, Nelson, British Columbia.



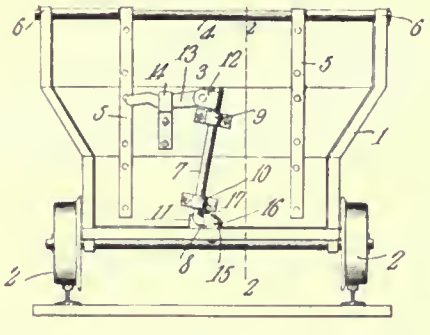
An electrochemical apparatus, comprising the combination of three terminals in a set, slit longitudinally, and an independent electrode arranged in the slit of each terminal and frictionally held thereby, the electrode in the middle terminal adapted to receive the deposit and the several terminals connected up in circuit.

ATTACHMENT FOR HOISTING-ENGINES.—No. 878,218. Harry Maker, Hibbing, Minnesota.



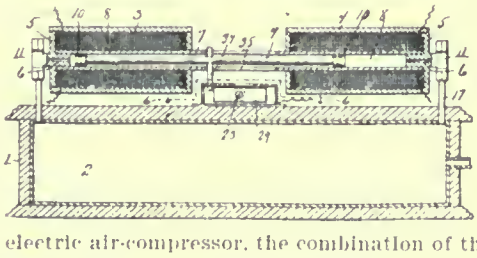
The combination, with a hoisting drum, having a cable wound upon each side of the centre thereof in opposite directions, a driving shaft geared to the middle portion of said drum, engines having their pistons connected to the ends of said driving shaft, a transverse pipe connecting the cylinders of said engines, a fluid pressure supply pipe leading into said transverse pipe, a throttle valve having a suitable lever and located in said supply pipe, a cylinder, a piston therein connected with said lever.

LATCH FOR MINE-CAR DOORS.—No. 874,872. Christian H. Smith, Tranger, Pennsylvania.



Combined with a door, an inclined latch bar having a laterally projecting tapering finger on its lower end, bearings for said bar, parallel arms on said bar above and in contact with said upper bearing, a lever pivoted between said arms and a keeper on said door for retaining the latch in closed position.

ELECTRIC AIR-COMPRESSOR.—No. 878,260. Nelson M. Watson, Detroit, Michigan.



In an electric air-compressor, the combination of the reciprocatory plunger, the air cylinder within which said plunger works, an air reservoir, means connecting said reservoir with said cylinder to afford a passage for the air, an electric circuit including an electro-magnet for reciprocating said plunger, means actuated by the plunger in its movement for cutting said magnet into and out of circuit, and means connected with the cylinder and actuated by fluid pressure for opening said electric circuit.

METAL BELT-LACING.

It is generally noted that at the present day steel belt-lacing is superceding the old style method of common string lacing that had been used to unite the ends of belts. It is difficult and at times impossible to make a durable conjunction with the ordinary string lacing. Many experiments have been made with wire lacing and various forms of iron hooks, to obtain strength and durability. These several methods are still in wide use. However, all seem to be working toward a lacing that will give at once an elastic joint, requiring no tools to apply, able to stand the strain and still have a smooth light appearance, enabling it to pass without jar or slip over the lightest pulley.

A popular and widely used metal lacing is made by the Bristol Company of Waterbury, Conn. A complete line is made of over 100 different sizes, suited to all kinds, widths, and thicknesses of belting; this marks a notable advance for in the beginning this lacing was made only for leather belts as shown in Fig. 1, showing the lacing ready to apply and the finished joint. Encouraged by success, different

Fig. 1

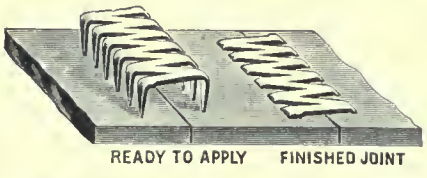


Fig. 2

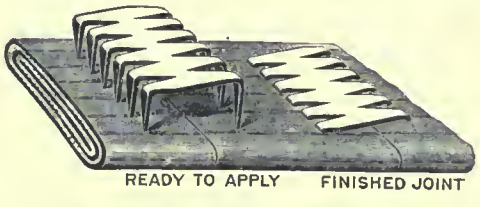

Fig. 3

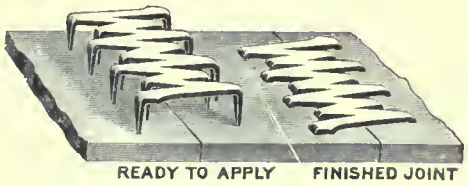


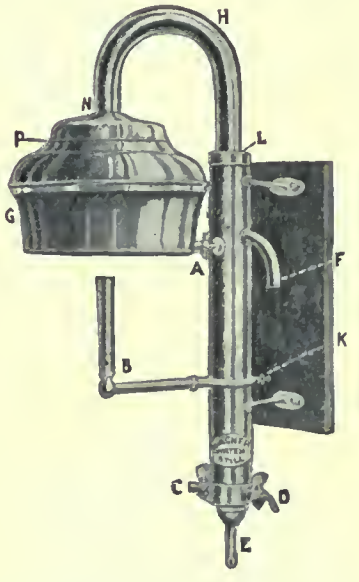
styles were added (as Fig. 2) for cotton, rubber, and woven belts, and later a lacing designed for general use having a staggered point (Fig. 3), which in large sizes has been found to be the only thing that will adequately join a conveyor belt. This lacing is made of the toughest cold-rolled steel cut into a continuous zig-zag form, and so proportioned as to give maximum strength with a minimum amount of material. The wedge-shaped points when driven through the belt, force the fibres aside without cutting them, hence the ends of the belt are not weakened, as when holes are punched. The lacing makes a smooth and elastic joint and is easily and quickly applied without any special tools, the spurs being driven through upon a piece of soft wood after the ends of the belt to be joined have been brought evenly together. The belt is then turned over upon the pulley or any convenient piece of iron and spurs clinched, bending them toward the joint.

The lacing is furnished in lengths varying from one to three inches (No. 1 by quarter inches), it being always possible from a box of assorted lengths to find two or more pieces of lacing which, together, may be used for a belt wider than three inches. For rubber, cotton, and woven belts the space between the spurs is a trifle greater than in the corresponding sizes designed for leather belts: thus a better grip is obtained on the fibrous end of such belts. For both leather and cotton belts the staggered point will answer the general need and combines the best features of the other two styles.

The Bristol Company now has machinery that enables it to turn out 1200 boxes per day, and a large addition to plant and machinery is now being made to take care of the continually increasing business.

WAGNER WATER-STILL.

Few people, aside from professional men, appreciate the value in the matter of health of absolutely pure distilled water. Filtered water is not pure and disease germs are not destroyed or eliminated by ordinary filtering processes. Much of the distilled water in bottles tastes 'flat,' but this objection to the use of distilled water for drinking may be removed by the employment of the new Wagner Automatic Water Still, the patent rights to which are controlled by the Wagner Water Still Co., of Chicago, Illinois. This device is in no manner to be compared with the cumbersome, ungainly, and laborious stove still, with its consequent care of refilling with water at frequent intervals,



making it a source of annoyance and hardship to the housekeeper. It is simple in operation, of convenient size, and can be attached above any sink or lavatory. The Wagner still can be operated all day or one hour per day, as desired; it requires no refilling with water—it re-fills itself automatically at all times. It is made in four sizes of capacity respectively, of ½ gal. per hr, 1 gal. per hr., 1½ gal. per hr., and 2 gal. per hr.; the ½ gal. per hr. capacity is the accepted household size. This device may have solved the drinking water problem, as it delivers absolutely pure, cold, aerated, distilled water at a minimum cost.

AN IMPROVED WATER-LEVEL GAUGE.

It is often advantageous in hydraulic engineering to automatically register the fluctuations in height of water, in head and tail-races, rivers, reservoirs, canals, sewers, forebays, etc. Many devices have been used for this purpose, but in practice, troubles have resulted from mechanical complexity, difficulty of installation, and the effect of cold weather on this apparatus. These objections have been overcome in the Bristol water-level gauge by using air-pressure for transmitting the motion. A double bell casting is placed permanently at the lowest point to which the water will fall. Between the halves of the bell a diaphragm of thin sheet rubber is placed so that the water pressure below compresses the air above, this pressure being transmitted through a flexible copper tube to the recording portion. It is seen, therefore, that all moving parts have been eliminated except the rubber diaphragm, which is permanently placed below the freezing point in the water. The recording portion may be put at any convenient distance from the water, and can be equipped with either daily or weekly charts of almost any capacity. These recorders have also been developed for registering the depth of volume of oil in fuel-oil or storage tanks. They are made by the Bristol Company and described in their new bulletin, No. 69, which will be sent upon request from the nearest office—New York, Chicago, or Waterbury, Connecticut.

Editorial.

OUR CONTEMPORARY, *South African Mines*, has resumed its old name, *The S. A. Mining Journal*, which it bore in the days before the Boer war. The proprietor, Mr. Clem D. Webb, is to be congratulated on the useful work his paper is performing for the mining industry of the Transvaal.

WHILE opposed to the hippodroming that masquerades in the guise of mining, we are glad to chronicle any new discoveries; therefore we print a good photograph showing the appearance of Rawhide, the scene of the recent rush in Nevada. A letter from our correspondent, Mr. Algernon Del Mar, gives the latest news. At an early date we expect to publish a more critical account.

REDUCTION OF DIVIDENDS by the Calumet & Hecla, American Smelting, Amalgamated, Federal Mining & Smelting, and other representative industrial corporations has now given the measure of the decrease in profits due to the fall in the prices of metals, itself the consequence of a general commercial depression, the inevitable sequel of over-expansion of credit and reckless speculation. The actual shrinkage in copper profits, whether from mining or trading, amounts to nearly 75 per cent as compared to the maximum attained a year ago, and it affords a striking commentary on the confident assurances given by insiders when copper was selling at 26 cents per pound.

THE ARTICLE on 'Crushing Ore' by Mr. M. P. Boss is likely to prove interesting to many readers, for Mr. Boss is a veteran millman, who has done a great deal more than merely write on this subject. As the inventor of the continuous-pan system he is well known to silver miners, and in more recent years he did much to develop the metallurgical practice of the Pachuca district, in Mexico, blazing a metallurgical trail for the younger men, who are now invading the habitat of the patio process and applying cyanidation to the ores of Real del Monte.

IN THIS ISSUE we publish a condensed account of the recent rock-drilling contest on the Rand. It was an interesting competition, due to the enterprise of our contemporary, *South African Mines*, a weekly journal published at Johannesburg. The prize of $500 was won by the Gordon drill, named after a former American consul at Johannesburg, invented by Messrs. Hellman and Bayles, and manufactured by Fraser & Chalmers, the representatives of the Ingersoll-Rand Company. This drill has been used in the Robinson mine for a year, and has enabled the cost of mining to be reduced to a notable degree.

Having regard to the weight of the drill and the amount of air consumed, the work accomplished by the drill was extremely creditable. It is fair to add that the Hardsoeg Wonder drill was prevented, by the misfortunes of the operator, from entering into actual competition, and one or two other drills of acknowledged usefulness were not represented in such a way as to afford a general test. Moreover, the heavy drills of the percussive type were under a disadvantage, the whole purpose of the contest being to ascertain the drill best fitted to replace Kaffir labor in narrow stopes following the angle of the quartz ore of the Main Reef Series. It is a notable triumph for the drill of the hammer type.

WE NOTE, with pleasure, that the Government of the United States has decided to proceed no further in the case against the Mountain Copper Company. The litigation grew out of complaints against damage supposed to have been done by smoke from the smelter at Keswick, in Shasta county, California. The trouble began in 1897, and in 1898 the Circuit Court granted an injunction, against which the Mountain Copper Company took an appeal. The decision of the lower court was reversed, and thereupon the Government appealed to the United States Supreme Court. No decision was reached, for the Government has now withdrawn its case, the smelter company agreeing to pay $25,000, the amount of money measuring the damage supposed to have been done to the timber land above Keswick. The Company has always expressed its willingness to pay for actual damage done to the forest reserves and, apparently, the Government has taken the Company at its word. In the meanwhile the smelting industry of Shasta county has grown enormously and is the mainstay of a large population. Local sentiment has veered and there is every inclination to treat the smelting companies fairly, but this reasonable state of mind did not supervene until after the Mountain Copper Company had moved its smelting operations from Keswick to Martinez.

SPEAKING OF ORE-STEALING, it may startle some of our readers to be told that trustworthy information warrants the statement that fully $1,000,000 worth of ore was stolen during the past year from the workings of the Goldfield Consolidated Mines Company, in Nevada. The 'high-grading,' as it is termed, was carried out on a large scale and through a great variety of channels. Detectives have been put to work and shipments of stolen ore had to be detained at Salt Lake, Denver, and San Francisco, pending further enquiry. Some of the local police were in league with the thieves and facilitated the trade in stolen ore. A cyanide plant, with a small roaster and leaching vat, was found next door to the office of an under-sheriff. Scores of bogus assaying establishments did a lively business with 'high-graders' and shipments of the product were sent to the outlying districts to be returned as the yield of other mines. A large part of the $1,000,000 that was stolen will be credited to mines in other Nevada camps. In some cases elaborate schemes were concocted to divert suspicion. Ore was shipped in women's trunks and holes in the ground were bought to serve as blinds. Speaking of thefts of this kind, we are reminded of a fatality that occurred at Telluride, in Colorado. A mill-hand who had stolen some amalgam retorted it early one morning in the basement of his house and the fumes killed his sleeping wife and two children in the room overhead. At Butte another amalgam thief hired a wagon and a pair of horses, to go into the mountains and retort his amalgam. He was careless as to his team and salivated both horses.

A Financial Farce.

RAWHIDE appears destined to illustrate most of the bad features of mining misadventure, while emphasizing the wonderful energy of the exploiters of mineral wealth. Rich ore has been found, a stampede of gold-seekers has ensued, and on the basis of a few promising prospects there has been constructed a fearful fabric of flamboyant speculation, reckless company-mongering, and downright misrepresentation. There are plenty to say soft somethings and inane nothings concerning these travesties of mining, there are plenty of papers willing to sell their advertising pages, if not their editorial columns, to the predatory mob of promoters, pseudo-experts, bucket-shop gamblers, and touts. It is the province of the journals devoted to the real advancement of the great industry of mining to speak out plainly, and it is to the interest of Rawhide itself that all this slime of flapdoodle be separated from the few particles of truth available at this time. Exaggeration, misrepresentation, and buncombe will not make a mining camp prosperous: on the contrary, they deter the commencement of the actual work that makes a mine out of a hole in the ground. Thus, for example, the three pages published in the San Francisco *Chronicle* last Sunday under the title of a 'Market Review of Nat. C. Goodwin & Co., Mine Operators and Stock Brokers,' can have no other effect except to discredit the new district in the eyes of any experienced man. It is said that "several geologists and mineralogists of national reputation * * * without exception declare that all indications point to the permanency of the ore deposits." This is pure and unadulterated fabrication. No such men have said any such thing. There is no evidence to warrant anyone in predicting the persistence of the deposits. That can only be proved by mining, not by 'market letters.' Then we are told that "the genesis of the ores is three-fold, viz: stock-works, impregnation, and replacement." This is balderdash, mere jargon intended to impress the ignorant public. It is more nearly true that the genesis of this scheme is stock-jobbing, working the public, and the replacement of the money of the many into the pockets of the few. Next, it is asserted: "That some of the largest bodies of high-grade ore ever discovered in the world exist in these hills is now conclusively demonstrated." That is the vapor of words, for not enough work has been done to

prove anything, and it is on this very absence of proof that these schemers base their talk of potentialities of wealth. It is claimed that the gold has been deposited by ascending solutions and that it is associated with silver, therefore it is doubly certain that the deposits are 'permanent'—meaning persistent. It would be wearisome to quote further, but this kind of 'market letter' is a good example of the misuse of a smattering of scientific terms to cloak wholly unscientific statements. It reminds us of the superintendent who wanted to know how 'metasomatic' was spelled and, when told, he was asked why he needed to spell it. He replied: "Oh, I just put in a few of those words to play up to the directors; they like it; it sounds fine." But all this childish nonsense is only part of a game, the purpose of which is obvious. We pass on to a more serious aspect of the case. Mr. Goodwin is, or was, widely known as a clever actor. It was worth the price of a theatre ticket to see him interpret the vagaries of human nature, and now, having made an honorable name as a legitimate actor, he lends that name to a financial farce. Mr. Goodwin's opinion on a mine is worth as much, not a bit more or a bit less, than that of any other man wholly inexperienced in mining; he is lending his name as a lure to catch the people who know him to be a good actor and do not know that he is utterly ignorant of mining. It is the old story, the story of using the names of people of title, celebrities, and notorieties in order to bait a stock scheme. The Earl of Dufferin, Admiral Melville, the Governor of Nevada, a whole lot of deluded and deluding men have played their part in the comedy of errors that ended in a sordid tragedy. It is bad acting and pestilent finance.

Mining Law.

REFORMATION of the mining law is the subject of an interesting letter from Mr. E. A. H. Tays appearing on another page. Evidently our contributor has his eye on the Mexican law, for he suggests amendments that would cause the American law to resemble that of our southern neighbor. The law of the apex is open to severe criticism, undoubtedly, but it has become the fundamental concept of our statutes, and any change to acreage without extralateral rights would mean a radical transformation throughout the multiple regulations enacted by the Federal, State, and District authorities. It is not one enactment that will have to be changed but the basic principle of all the legislation on the subject. For instance, the right of discovery: this is the first privilege of the prospector and miner; by finding mineral in place he is privileged to acquire the right to so much of the length of the lode and to an indefinite depth. Now, change from apex to acreage: the discoverer delimits a certain number of acres or square feet, not knowing the dip of the ore, the shape of the orebody, or the final significance of the outcrop. These factors are ascertained by subsequent mining; at the time of the discovery they are unknown. Acreage may constitute a farm, it does not make a mine. Again, a large part of the public domain has been alienated; if you try to apply a new law side by side with the facts created by the old law, if the apex claims abut and adjoin the acreage locations, then you have confusion worse confounded, and the regrettable litigation of today will be succeeded by conflicts so complex as to make existing evils look like heavenly peace. Of course, no new law could be make retro-active, for that would be an invasion of constitutional rights. Even a location—let alone a patent—is the result of an invitation by the Government to the miner to exercise certain privileges that cannot be withdrawn without congressional amendment of the most radical character. Only in absolutely new territory, where the miner has made no entry, could a new law be applied. How much of such territory is there? Is there enough of it to warrant the subversion of customs already deeply rooted in the great mining regions of America?

Mining and Metallurgical Societies.—I.

MANY of our friends in the profession have been invited to join in the organization of a Mining and Metallurgical Association, on the initiative of Mr. H. M. Chance, of Philadelphia. Among those who have become charter members are L. S. Austin, H. Foster Bain, J. Parke Channing, J. Morgan Clements, E. L. Dufoureq, S. F. Emmons, J. R. Finlay, F. Lynwood Garrison, W. R. Ingalls, John D. Irving, James F. Kemp, Waldemar Lindgren, George W. Maynard, F. J. H. Merrill, Forbes Rickard, J. E. Spurr, and Pope Yeatman. In a recent issue we discussed the proposed professional blue-book and we are glad to learn that this feature of the undertaking is likely to be dropped. There remains the larger scheme. We have been asked to express an opinion concerning it, and as any such new departure is keenly interesting to most of our readers, we venture to speak frankly.

The members of the mining and metallurgical professions, among whom are included the economic geologists, feel the need of an organization so constituted that membership will have a meaning and so managed that expression may be given to opinions concerning professional ethics and national questions as they affect either the mining industry or the welfare of those engaged in that industry. For instance, the question of a Federal Mining Bureau should have been referable to such a representative organization; so also the standardization of terms used by engineers, as well as professional practices generally. We can best ascertain what scope there is for a new society by reviewing the work already being done by the three leading organizations, namely, the American Institute, the Institution in London, and the American Mining Congress.

The Institution of Mining & Metallurgy, in England, is performing a function which is more nearly the aim of the new association than any other mining society now existing. Founded in 1892, the Institution has always aimed to maintain a select membership, and while at first this took the form of a coterie, it has been successful, on the whole, in

restricting election to men of honorable record. This feature was discussed in these columns recently, so that we need only say further that the by-laws provide for candidates being of a specified age and experience, and in good standing professionally. In this way membership has been rendered as select as practicable and a fairly good standard has been maintained. The council is large and representative in a broad Anglo-American way; the presidency is deemed a high honor. In many matters of public interest, the Institution, by its council or by special committees, has taken part in shaping professional customs, in standardizing terms, and in moulding current thought concerning technical education. The pamphlets and the bound volume of its proceedings, as published annually, have enriched technical literature, and there is evidence of steady improvement in the quality of the writings. Undoubtedly the Institution, in the phrase of the period, "has made good." In the first clause of the constitution it is stated that: "The Institution of Mining & Metallurgy is established for the general advancement of mining and metallurgical science." That purpose is in course of honorable fulfillment.

But we have a similar organization in America and, when all is said, was not the Institution in London modeled on that of the American Institute of Mining Engineers? Certainly. The American Institute was the first to demonstrate the great usefulness of such an organization and in the quality (as well as the quantity) of its published transactions it has held the premier position for over 35 years. But the American Institute is a publishing institution only; as an organization it has been so generous in membership as to include not only professional men but "persons practically engaged in mining, metallurgy, or metallurgical engineering." Thus mine-owners and foremen, of no technical education and with no professional ties, have been elected; membership has come to mean chiefly a willingness to pay 10 dollars per annum for pamphlets and a volume of well-edited technical writings. By Rule No. 1, adopted at Wilkesbarre on May 16, 1871, it was stated: "The objects of the American Institute of Mining Engineers are to enable its members * * * to meet together * * * for the purpose of reading papers upon and discussing subjects which have for their aim the economical production of the useful minerals and metals, and the safety and welfare of those employed in these industries." In 1873, and again in 1875 and 1877, the rules were amended, and a wider scope is indicated by a change in the first rule, which now reads: "The objects of the Institute are to promote the arts and sciences connected with the economical production of the useful minerals and metals, and the welfare of those employed in these industries, by means of meetings for social intercourse, and the reading and discussion of professional papers, and to circulate, by means of publications among its members and associates, the information thus obtained." The definition of eligibility to membership remains today as it was in 1871. By Section 2 of Article X, in the constitution as adopted on February 21, 1905, it is expressly stated: "Neither the Council nor the Institute shall officially approve or disapprove any technical or scientific opinion or any proposed enterprise, outside of the management of the meetings, discussions and publications of the Institute, and the conduct of its business affairs by the Board of Directors." By Section 3, it is provided that: "Special Committees may from time to time be appointed by the Council to make investigations and prepare reports for presentation to the Institute, but no action shall be taken binding the Institute for or against the conclusions embodied in any such reports." The committees for which provision is thus made have not as yet been appointed, nor are they likely to be, for the whole policy of the Institute and that of its Secretary has been to avoid committing the Institute to any expression of opinion on matters outside of its own particular affairs. Nondescript membership is not favorable to joint action on public matters, heterogeneous character prevents any real solidarity, and thus the Institute, under the leadership and strong individuality of its talented Secretary, has become a great publishing institution that yearly adds a splendid volume to the reference library of the profession. As an engineering society it is a failure. There are reasons for this, other than the by-laws just discussed: the Institute has 4250 members and associates; the Institution has 1500. Of the Institute's members, there are about 450 living in New York and in the adjacent cities, that is, about 10% of the members use New York as a place of daily business. Of the Institution's members and associates, 450, or not less than 30%, reside in London and its suburbs. This has led to the holding of monthly meetings, at which the attendance is large; moreover, a large proportion of the members foregather at an annual dinner, besides other opportunities of organized fellowship. The Institute depends upon a scattered membership, distributed over an entire continent. Meetings are held annually or semi-annually; they are attended by from 1 to 5% of the members; the attendance, while representative in character, is much too small to emphasize the social side of the organization. The discussions are not nearly as general as in London, where twenty or thirty men will take part at a single monthly meeting; in New York the ventilation of ideas is carried on mainly by means of essays fired at long range, and while these often have a value greater than the impromptu speaking of our English friends, they lack the spontaneity and directness of an open debate. These comparisons and criticisms simply emphasize the fact that the Institute has developed a definite character and policy, the result of its constitution and habitat. It is too late in the day to expect any change. Certain work that it might have done, it has chosen to set aside; the work it has elected to do, it has done astonishingly well. Any new organization should strive as much to do what the Institute has left undone as avoid trying to perform the duties the Institute performs so well.

Next week we shall discuss the work of the Mining Congress, as a representative organization, and thus we can come to an intelligent idea as to whether there is need for a new association of mining engineers and metallurgists.

Personal.

C. W. Purington is at Vienna.

M. P. Boss has gone to Salt Lake City.

E. L. Dufourcq has returned to New York.

Curtis H. Lindley is at Washington, D. C.

Nathan T. Mansfield has gone to Rawhide.

George A. Schroter was in Sonora last week.

John E. McManus, of Seattle, is at Rawhide, Nevada.

Alfred von der Ropp is at Tour-de-Peilz, Switzerland.

Thos. R. Barbour is expected in San Francisco next week.

H. W. Hardinge has returned to New York from Cobalt, Ontario.

Courtenay De Kalb has been examining mines at Searchlight, Nevada.

H. G. V. Adler has returned to London from a visit to Cobalt, Ontario.

T. J. Hoover is expected here, on his way to London, from Australia.

Louis S. Noble has been examining mines in western Chihauhua, Mexico.

Robert H. Richards is making a short professional trip to Pennsylvania.

H. De C. Richards is examining a mine in Siskiyou county, California.

Oscar H. Hershey has been seriously ill and is convalescing at Los Gatos, California.

Zebina Lane, of Perth, Western Australia, arrived on the *Aorangi* and is now in San Francisco.

Ernest A. Haggott has been appointed manager for the Big Stick Gold Mining Co., in Arizona.

R. V. Norris, of New York and Wilkesbarre, is here in connection with the Monterey coal enterprise.

W. A. Carlyle has returned to London, having completed his inspection of the Le Roi mine, at Rossland, B. C.

Grant E. Davis, formerly at Manhattan, Nevada, and W. P. Cain have opened a mining engineer's office at Rawhide.

Percy Williams is at Vancouver, B. C., on his way to the Fraser river, where he is directing the operations of a gold dredge.

Henry Adams, of New London, Conn., is here as consulting engineer to the Brush Creek hydraulic mines, in Plumas county.

Charles A. Gehrmann, former manager of the Stanley mine, Idaho Springs, Colorado, is president of the Bank of Rawhide, Nevada.

Geo. W. Lloyd, E. F. Yates, and N. J. Churchill are asociated together in mining engineering work, and have opened an office at Rawhide, Nevada.

John Hays Hammond has recovered sufficiently to be able to return from San Francisco to Santa Barbara. His convalescence is progressing most satisfactorily.

T. H. Oxnam has returned from a trip of inspection of the Desert King mines, in San Bernardino county, Cal., and is now on his way to examine the Palmarejo and Guerra al Tirano mines, at Chinipas, Chihuahua, Mexico.

L. S. Austin has returned to the Michigan College of Mines at Houghton, from Milwaukee, where he had been called to give expert testimony in a suit against the Nibiack Copper Co., of Alaska, involving the treatment of the ore which that company is mining.

S. F. Emmons was the guest of honor at a dinner given at the Columbia University Club, New York, on February 26. The occasion was a demonstration, by graduates of the Columbia School of Mines, of appreciation to the distinguished geologist and his labors as a scientific man. James F. Kemp presided. Those present included John A. Church, Benj. B. Lawrence, J. H. Banks, J. Parke Channing, Robert Peele, A. L. Walker, Arthur S. Dwight, Joseph Struthers, F. M. Simonds, C. P. Berkey, E. C. Holden, A. C. Beatty, J. D. Irving, O. B. Perry, E. N. Skinner.

General Mining News.

CALIFORNIA.

EL DORADO COUNTY.

The Woodside-Eureka Co. is planning to replace the hoisting and pumping machinery on the old Eureka shaft and the re-opening of the old Eureka workings.——At the Magnolia mine the large pit bottom is being sluiced and the bedrock cleaned up.——At the Jones Hill mine, new sluices are being put in place and active preparations are being made for the immediate resumption of drifting. H. Ward is superintendent.——A new pump is being installed at the new shaft of the Little Chief mine, and sinking will be resumed next week.——The Fowlar Co. is taking out rich ore from a vein near the Delwisch mine.——At the Blue Rock mine work in the shaft has been temporarily suspended and the water is being used for sluicing in the pit, which has been successfully worked for many years. ——At the Collins-Bacchi mine work will be commenced on a new shaft about the beginning of April.——The Clipper mine has been recently purchased by W. A. Salisbury and the shaft will be sunk to 500 ft. as soon as the necessary machinery can be erected.

NEVADA COUNTY.

(Special Correspondence).—The Deadman's Flat district is rapidly becoming one of the busiest points in the county. Exploration and development work is going on at several properties, with good results.——At the Kenosha the shaft is still going down in good ore. Much development work is under way in the 300-ft. level, where excellent ore is exposed. The main orebody is showing well.——At the Normandie several men are sinking the shaft to exploit ore exposed near the surface workings. Promising indications are obtained as work progresses.——Some work is going on at the California, where good ore has been developed. ——Extensive developments are progressing in the lower levels of the Central shaft. The orebody in the new workings is of excellent grade.——The boilers, compressors, steam pumps, and the rest of the plant at the Banner mine has been purchased by George Bros. of Grass Valley.——An Eastern mining company has bonded 160 acres of land from local people. The price is said to be $50,000. The holdings contain a 40-ft. lode of gold, copper, and lead ore. The land is near the Mason ranch, 13 miles below this city. The bonders are endeavoring to secure additional land adjoining that recently secured. San Francisco people own much of the desired territory, and a representative will be sent to that city to interview the owners and make an offer.——The Leduc G. M. Co. has been organized by San Francisco and local people to work mineral holdings on the Leduc ranch. A tunnel will be driven to tap the gravel channel and quartz vein which were worked to a shallow depth several years ago. A compressor and 35-hp. engine will be installed. B. A. Penhall is general manager. ——Work is progressing steadily at the Midas mine. The ore-shoot has not yet been struck, but there are good indications of its near proximity.——The adit at the Fairview mine is being driven steadily. Considerable milling ore has been blocked out. It is the intention to erect a 20-stamp mill during the summer. C. M. Wilson is manager. ——Work will shortly commence on a new prospect shaft at the Spring Hill property. The ore exposed in the adit has encouraged the owner, C. K. Lakenan, to proceed with active development.——Good ore continues to come from the Home workings. The large body of low-grade ore in the Champion is also showing well.——A large force of men is working at the Mountaineer mine. Good ore has been encountered at several points.——The heavy fall of snow last week insures a plentiful supply of water for mining purposes during the coming season.

Grass Valley, March 9.

SAN DIEGO COUNTY.

A discovery of gold ore is reported near Dulzura, about 2½ miles southeast of the town. It is in a mountainous district and about a mile beyond the end of the road. The ore is free milling but of low grade.

SHASTA COUNTY.

The case of the U. S. Government *v.* the Mountain Copper Co. has been dismissed in favor of the latter. The case is the result of an action which has been carried up to the Supreme Court at Washington on account of the damage done to timber near the smelter by smoke. The appeal has been withdrawn and the Mountain Copper Co. has agreed to pay for the damage done to the Government forest lands. This is a test case, on which the future of other copper smelters in the district depended for a favorable decision.

SIERRA COUNTY.

Development work is being carried on at the Fairview mine above Relief hill, under C. W. Wilson's management. ——L. P. Woodbury is considering the purchase of the Tightner mine with a view to making a consolidation of several properties adjoining.

TUOLUMNE COUNTY.

Work will be resumed at the Melones mine immediately. Arrangements have been made between the company's officials and the miners' union and the strike has been declared off. The underground shift will be 8 hr., with 30 min. for lunch, and 8 hr. in the mill with 1 hr. for lunch. It is expected that 65 or 70 men will be employed within 10 days.

IDAHO.

IDAHO COUNTY.

(Special Correspondence).—Patrick J. Jennings of Portland, Ore., has completed the purchase of the Fifteen-Two and the Mountain Con. groups of claims in the Elk City district. This deal has been pending for several months, and was concluded by a cash payment in full for the properties. John Massam, of Spokane, is associated with P. J. Jennings. The Fifteen-Two consists of two claims having a vein of gold-bearing quartz from 12 to 35 ft. wide. The other comprises five claims on a quartz dike which stands about 18 ft. above the surrounding country and extends for over a mile in this manner. Development work is to be commenced early in the spring on the Fifteen-Two by driving a long adit to secure a depth of 400 ft., and on the other by means of two adits driven in opposite directions from the creek-bottom, which cuts the vein in two. Roads must be constructed and a plant is to be installed this summer. A 10-stamp mill will be erected, with provision for increasing to a 40-stamp capacity as development makes this necessary. Water-power has been secured, it is stated, which is capable of developing sufficient electric power to run all machinery at both mines, the longest power line being about eight miles.

Elk City, March 6.

SHOSHONE COUNTY.

(Special Correspondence).—The Nipsic Mining Co. Ltd. has been incorporated in Spokane, to operate a group of six claims lying west of the Hercules, near Burke, Idaho, the chief of which is the Father Lode, upon which a great deal of development has been done. The company is composed of prominent mining and financial men of Spokane. This property shipped several hundred tons of ore a few years ago which averaged $66 per ton, and it is now estimated that $118,000 worth of ore is already blocked out in the three adits above No. 4. This does not include two rich but small shoots of ore which have been stoped in No. 1 and 2, but which were left to one side of No. 3. A third large ore-shoot, principally concentrating, has been opened in No. 3 adit, where a drift has been run. The same shoot has been tapped in both tunnels above. No. 4 adit, situated 167 ft. below No. 3, is now into the hill 450 ft. and has also reached an ore-shoot. It is the intention of the company to continue this adit until it strikes ore several hundred feet ahead, which is believed, from surface indications, to be of larger extent than any yet opened. A small crew of men which has been at work some time is now to be increased and development work extended.——The first complete month's run of the Rex mill at Wallace was com-

pleted Feb. 29, and nine cars of concentrate and one of crude ore were produced and sent to the East Helena smelter. This is the first car of crude ore ever shipped, although the mine was a large producer several years ago. The ore produces concentrates running 60% lead and about 5 or 6% zinc. Ore removed in drifting at the foot of the winze carried 10% lead for the entire distance of 250 ft. No stoping has as yet been found necessary to keep the concentrator running three shifts a day. It is treating 190 tons per day, and would have a capacity of 60 tons more if water could be obtained in sufficient quantity. This produces 25 tons of concentrate daily. The drift at the foot of the winze is being carried westward as rapidly as possible, and is now within 24 ft. of an ore-shoot which is well defined in the tunnel above. When this is reached a considerable quantity of shipping ore will be available.——Several business men of Spokane, Wash., have recently become interested with J. Francis in the lease and option on the Rex. As soon as the new hoist has been installed at the winze, arrangements for which have already been made, sinking to a depth of 286 ft. will commence. The present hoist will be used for lifting timbers elsewhere in the mine.

Tool-Car at the Central North Star Shaft, Grass Valley, Cal.

Wallace, March 8.

The Gold Buffalo Mining Co. owns six claims near Buffalo Hump Mtn., including the Wise Boy. During last summer's run it was learned that most of the gold went out with the slime, and a cyanide plant is to be installed to obviate this loss. Improvements at the mine consist of steam and electric machinery, buildings, and an aerial tram 960 ft. long connecting the No. 2 tunnel with the mill.——Development consists of two adits, the first 110 ft. long, with a drift in ore 250 ft. long, and the lower adit, 387 ft. long with a 700-ft. drift. These tunnels are connected by an upraise 180 ft. high, which contains a manway and ore-chute. It is now proposed to drive a lower tunnel directly from the mill, thus securing greater depth, and also giving cover for work during the winter, as the heavy snows make difficult and expensive the operation of the high tramway.——The Charles Dickens has made another discovery of concentrating galena in its No. 2 adit at a point 100 ft. beyond where stoping is now in progress. The Dickens No. 2 adit is on the vein its entire distance, or practically so, and the ore struck at this time was reached by a cross-cut but 4 ft. long. The cross-cut being driven 9 ft. into the ore, has not yet given any indication of the other wall. This is thought to be an entirely different ore-shoot from the one now being worked. The Dickens has but recently been developed to the producing stage, and had shipped but a small amount of ore when the concentrator burned down. The concentrator is now being rapidly rebuilt on a larger scale, and it is stated by an official of the company that the mill will be running by April.——The Evolution mine, which closed last December, is to be reopened within a short time. F. R. Crocker is superintendent. The Evolution is one of the oldest locations in the Cœur d'Alene, and is favorably situated for economical development, with water capable of generating 350 hp. close at hand, through a flume controlled by the company, and the O. R. & N. but a short distance from the shaft. Development at present consists of an adit several hundred feet into the hill, which has shown good bodies of galena, and a main working shaft 300 ft. deep, situated some distance below the adit, from which several cross-cuts have been driven. Galena of concentrating and shipping grade has been shown in these cross-cuts. It is stated that machinery has now been ordered, and that the mine will be put on a shipping basis as fast as men and money can do it. The water-power will be developed within the near future.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The rejuvenation of the Tanyard, Jackson, and Gordon Hollow camps, west and southwest of Joplin, has been the greatest development of the last two months. In 1898 and 1899 these camps furnished the major portion of the camp's production, but during the drop in prices and the working out of the rich shallow levels these camps were deserted. The ores were mined only to a depth of 90 ft., where the shafts entered a heavy stratum of flint, which the miners thought to be bedrock. A strange occurrence was the fact that the ores were found from the very surface to the 90-ft. level. The finding of rich deposits of ore at lower levels in other portions of the field induced a company of prospectors headed by Col. H. H. Gregg to return to this old camp and prospect the ground at a lower level. The work was successfully accomplished by sinking one of the older shafts through the flint beds, and at a depth of 150 ft. a second run of zinc-blende was encountered. A mill has been erected, and the owners of the land are receiving a royalty of $1000 per month on what was considered to be barren ground. This was the first work, and it was followed by a rush of prospectors to take up old abandoned shafts and leases. The Emperor Lead & Zinc Co. entered an old shaft and, sinking it to the 150-ft. level, discovered a similar run of ore. This company also erected a new concentrating plant and the ore-body was found to mill 6% zinc-blende.——Across in Gordon Hollow the resumption of operations has been no less marked. Among the best strikes, and one of the first to attract a new lot of prospectors to the camp, was that made on the old Daisy D. lease. A drill was put to work in one of the old shafts, and penetrated four runs of ore running from 5 to 40 ft. in thickness. The shaft was then sunk deeper and the new levels developed. The company is now erecting a concentrating plant.——On an adjoining lease the Monitor Mining Co. has reopened the old Monitor mine and has developed a workable face of sheet ore. Two other shafts on the same ground are now re-opened and concentrating plants will be erected. In addition to these strikes of ore and erection of new plants, there are large numbers of prospectors just now entering the camp, who are sinking the old shafts deeper or drilling contiguous ground. The development work in progress will add a large quantity of concentrate to the output of the Joplin camp during the early spring months.——Following the strikes made by Col. H. H. Gregg, the Matthes Bros. secured the old John Jackson Investment Co. tract of land lying up on the prairie at the head of the old Jackson, Gordon, and Tanyard Hollow camps. The tract contains over 600 acres. Drills were put to work on the land, and to date there have been 24 discoveries of ore lying in a sheet-ground formation. The drills have only just begun, and will continue the work during the spring and summer. The ores all lie at a greater depth than was supposed in that camp, but the shafts now sunk at Jackson station show up a good body of milling

sheet ore. The Matthes Bros. have re-opened the old Arkansas mine, just on the edge of the prairie where it breaks into the hollows, and are now milling ore from this old producer which had been deserted for years.——North of the John Jackson land at Cave Springs the Herald Mining Co. has extended the limits of that camp by developing a new lease of sheet ground. Fifteen drill-holes were put down and two shafts have been sunk. Three runs of ore were discovered, the first at 107 ft., with a 25-ft. face; the second at 155 ft., with a 30-ft. face; and a third at 220 ft., with a 42-ft. face. The ore carries 4% of zinc-blende with a smaller quantity of galena. A concentrating plant has been placed upon the lease and will handle 250 tons daily. The company holds a 30-acre lease.——J. J. Pullen has developed a lease at Central City and has just completed a new mill. The mill replaces the one recently destroyed by fire. The underground work has resulted in the exposure of a 20-ft. face of high-grade ore. The driving has progressed sufficiently to supply the mill only half time.

Joplin, March 6.

NEWTON COUNTY.

(Special Correspondence).—Southwest of Granby on the Chase land a new area of sheet ground has been developed by Chase & Heaton. Twelve drill-holes were put down on the tract and 11 of these penetrated ore from 12 to 20 ft. thick. The drilling was deep and the ore was only encountered below the 200-ft. level. The drilling was always continued to the 300-ft. level. A shaft was then sunk upon the most favorable strike and ore was encountered from 212 to 232 ft. The company then sunk seven drill-holes immediately surrounding this shaft, in order to explore the orebody. All of them penetrated the same ore-bed, thus demonstrating that the ore underlaid at least four acres. A small test-mill was erected at the shaft, which demonstrated that the ore carried about 4% galena and zinc-blende, with the proportion between them of one to three. A new 500-ton concentrating plant has been erected and equipped with electrical power. In the immediate vicinity the Granby Mining & Smelting Co., the Illinois Zinc Co., and the Empire Zinc Co. have been drilling land, and the results have shown a wide area of this sheet ground, embracing over 800 acres. The ore occurs at the same level, taking into account the topography of the region.——North of Granby, the Granby Mining & Smelting Co. has had two drills at work demonstrating the extent of a sheet-ore deposit recently discovered at a depth of 300 ft. The company is now sinking a shaft to develop the new orebody. This marks the first attempt to work a deep deposit of ore in the Granby area.——On the prairie southwest of the town J. Roden has developed a new run of blende ore at the 100-ft. level. The strike is near the old Mascot mine, one of the greatest blende producers in the camp. A concentrating plant has been erected.——In the eastern end of the camp operations have been carried to a lower level in the Lady Bird and Fortune Teller mines. These have been exceptionally heavy producers of zinc silicate in the upper levels. Recently the Lady Bird shaft was sunk to a second run of zinc silicate, much richer than any worked in that mine before. The Fortune Teller, adjoining, followed suit and opened a still richer body of ore. The company operating it has now erected a concentrating plant, the first one ever built in the east end of the camp.

Saginaw, March 7.

MONTANA.

MADISON COUNTY.

The Mayflower Extension Gold Mining Co. has been organized to develop the Hidden Treasure, Long Island, and Jubilee lode claims, adjoining the Mayflower mine, which was an important producer. The property was examined before purchase by A. V. Corey, and it is expected that a continuation of the Mayflower orebody may be found on this claim, which is within 250 ft. of the old Mayflower ore-shoot. There are two shafts on the Mayflower, one 200 ft. and the other 300 ft. in depth. Drifting will be immediately commenced on the 200-ft. level.

NEVADA.

ELKO COUNTY.

Operations will soon be commenced by the Tuscarora-Nevada Mines Co. A four-compartment shaft will be sunk and a power plant erected. The 40-stamp mill will be equipped with concentrators and later additional reduction works will be added.

Gold Circle is one of the new camps that have recently been formed in Nevada. It is in the extreme western part of Elko county, north of the Southern Pacific R. R. The camp has about 300 people, and assays from $30 to $80 have been obtained from ore in prospect shafts 30 ft. deep. The Bamberger claim was the first discovery, and rich ore is also reported from the Spotted Dog, an adjacent claim, on which a tunnel 70 ft. in length has been driven.——Satisfactory developments are reported from the property of the Delmas Copper Co. on their properties in Lee canyon. A tunnel is being driven to explore a granite and limestone contact on which lodes of copper ore occur. Already two veins have been cut by the tunnel, which is 170 ft. in length. The tunnel will be driven 200 ft. farther to cut a vein which shows a good outcrop on the surface.

ESMERALDA COUNTY.

The legal contest between the Mine Owners' Association and the Goldfield miners' union resulted in a decision in favor of the former, by which the miners, under penalty of contempt, involving fine or imprisonment, must refrain from interfering in any way with the business of the petitioners, from using intimidation in any way whatever, either by picketing, visiting the houses of miners supplanting the union miners, or making threats of any kind, or from holding meetings within the Goldfield mining district. The injunction applies to each individual officer who is named in the pleadings, and to the members of the Goldfield miners' union.——The output of Goldfield for February is valued at $218,730. The Combination mine and mill treated 2300 tons, valued at $92,000. The Western Ore Purchasing Co. received 556 tons, averaging $100 a ton, as follows: Mohawk-Combination, 72 tons; Florence Annex, 147 tons; Black Butte, 15 tons; Daisy, 58 tons; Diamond Queen, 11 tons; Great Western, 33 tons; various dumps, 220 tons. The Nevada-Goldfield Reduction Works treated 1119 tons, valued at $54,330.

The ore shipments over the Tonopah & Goldfield railroad for the week ending Feb. 5 consisted of 223 tons from the MacNamara, 102 tons from the Midway, and 47 tons from the Tonopah Extension. The Tonopah Co. sent 4740 tons, the Belmont Co. 820 tons, the Montana-Tonopah 1100 tons to the mills, making the total shipments for the week 7032 tons. The total output of the Tonopah mines was 7032 tons, of an estimated value (the shipping ore being valued at $60 per ton and the milling ore at $20 per ton) of $155,520.——Sixteen machine drills are in constant use on the Belmont. Little of the waste is hoisted to the surface, it being used to fill up the old stopes. Good progress is being made in the No. 12 south cross-cut, 450 ft. east of the shaft on the 700 level. It is now out about 230 ft., 26 ft. having been driven this week. On the 800 level, raise No. 1 on the south vein, west of the cross-cut, is being pushed to connect with the No. 12 cross-cut on the 700 level, a distance of about 50 ft. having already been made. This raise is all in ore of good milling grade, the vein showing an average width of 3½ ft. Driving east continues on this vein and the drift is now 130 ft. long. On the 1000 level driving continues east on the Mizpah vein, which was cut on No. 5 north cross-cut, a distance of 13 ft. being made last week. The vein is the full width of the drift, with quartz showing on both sides, but is low grade in quality. An advance of 33 ft. was made in the No. 3 south cross-cut last week. The drift on the sulphide vein which was cut in the No. 6 north cross-cut is now 28 ft. east and 18 ft. west, and the vein improves as work progresses.

LYON COUNTY.

(Special Correspondence).—Ramsey district, 15 miles northeast of Virginia City, has a system of veins on the contacts of andesite and diorite. There are said to be 12

parallel veins of this character, containing free-milling gold ore. On the group of the Ramsey-Comstock M. Co., managed by A. H. Wayne of Goldfield, is a 400-ft. shaft with drifts on four levels disclosing a vein 25 ft. wide.

Ramsey, Feb. 29.

NYE COUNTY.

Construction work at the Round Mountain Reduction Co.'s works is nearing completion. The machinery is all in place, and little remains to be done now except to lay the pipe which will carry the water from the pumping station into the Elspass. The plant will be running at full capacity within a week. Contracts have already been made with several lessees to treat their ores.——The February payroll of the Round Mountain Mining Co. was $7000.——The lower adit of the Round Mountain Monster Co. is 305 ft. long, and numerous tungsten stringers have been cut. ——The McLean-Perkins lease sunk a vertical shaft nearly 200 ft. on the Shot Fraction.——The Hydraulic Co. will soon have a new pipe-line completed, and the heavy snowfall ensures a good season.

A report on the Nevada-Wonder mine made by R. H. Sanders states that the ore blocked out amounts to 11,203 tons assaying over $20 a ton, and 6215 tons assaying below $20 per ton. The ore at the bottom of the 500-ft. shaft was found to be low grade, but the workings at this level are 100 ft. north of the nearest known high-grade ore, and it is expected that this shoot will be found by driving south. There are 2000 tons of ore on the dump assaying $36 per ton.

A discovery of rich ore has been made about seven miles from Rogers in the Toyabe mountains, across the Big Smoky valley from Round Mtn.. The ore was found in the Buckeye mine in a 16-ft. raise, where an 18-in. streak of fine-grained galena with native silver was found. Owing to the deep snow it is difficult to get into the district.

STOREY COUNTY.

Interest in the new find in the West Comstock district is increasing. A number of people have visited the discovery, which has some promise of consistency. Wood and water are plentiful and the mining conditions are excellent.

WHITE PINE COUNTY.

At the Veteran mine of the Cumberland Ely the preparations for making regular shipments are nearly completed. The shaft is down 350 ft. and will be sunk to 400 ft. This work was started on Sept. 25 and has been continued at an average rate of 30 ft. a week.——At the Giroux mine the work of recovering the shaft is going on slowly. The working force has not yet reached dangerous ground, being still above the cave. Another run of ground occurred in the mine during the week, and this was from the old cave, which shows that the ground has not yet settled. It is hoped that the shaft may be saved, but it will probably involve great expense.

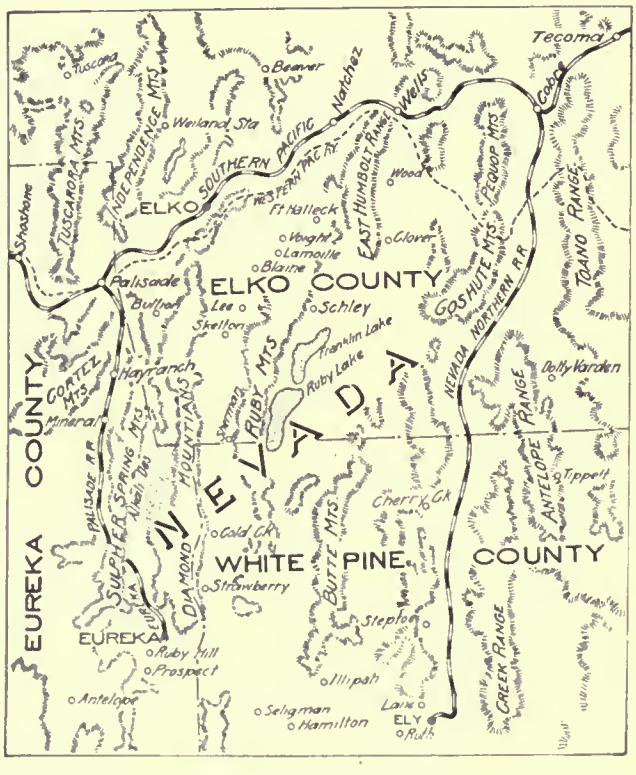
While doing assessment work on the Vesta mine to secure a patent a shaft was sunk 40 ft. This is said to have encountered the productive monzonite formation, and 4 ft. of sulphide ore containing chalcopyrite has been discovered. The shaft was sunk in a porphyry intrusion in limestone in a part of the Robinson district in which no ore has been found previously, and consequently the discovery is considered important. The Vesta mine adjoins the property of the Ely Northern Copper Co., and it is hoped that the productive area will prove to be greater than it has been generally considered.

Construction work at Ely is progressing well, and the concentrator and smelter of the Nevada Con. should be ready for operation by the beginning of May. By the middle of April the tracks of the Western Pacific will be opened for traffic between Ely and Salt Lake City.

NEW MEXICO.

SOCORRO COUNTY.

(Special Correspondence).—The Enterprise Mining Co. in the Mogollon district has let a contract to drive its main adit to connect the mine and mill. Hitherto the ore and mine supplies had to be sent over a steep and difficult trail which in bad weather was almost impassable.——Peterson & McGuire have bonded their Dry Creek property to J. Whiteside. The first payment has been made, and the new owners have advertised for bids to sink the shaft 100 ft. This property differs from most of the mines in Mogollon in occasionally producing high-grade telluride ore.——E. Craig, president of the Mogollon Motor Road Co., is again in the district and reports conditions of the road progressing smoothly. The company has purchased and tested its cars, which make the run between Silver City and Mogollon, a distance of 90 miles, in six hours. In wet weather the cars experienced some difficulty in making schedule time, as they were compelled to run over the same road used by the heavy freight teams. To do away with this delay, the company applied for a Government



Map of Eastern Nevada.

right-of-way, and has machine graders with which to construct the new road.

Mogollon, March 6.

OREGON.

BAKER COUNTY.

The discovery of ore recently made in the Greenhorn mountains was on the property of J. W. Fleegle and W. Clark, who have been developing it for several years. The vein at the surrface is from 15 to 20 ft. wide, and this has rcently been reached in a cross-cut adit. The ore is of good milling grade. The Psyche, joining it on one side, and the Snow Creek on the other, have both produced ore of high grade.——T. S. Kennerly is superintendent for the Highland Gold Mines Co. A cross-cut is being driven to cut the vein, but it will be several months before the objective is reached.——A low-level adit driven on the Wolverine mine by W. H. Robinson has cut the vein, which is 12 ft. wide. The ore has not yet been assayed.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Copper Key Mining Co. has decided to install a larger air-compressor, and the manager, E. L. Tate, accompanied by an engineer, is at the mine making investigations.——A group of 14 claims has been located on Hall creek, west of the Columbia river, on the South Half of the Colville reservation. On the group a wide vein has been traced two miles. The ore contains lead and silver carbonates, the lead assaying from 10 to 75%. A

contract has been made for a sale of the group for $30,000, full payment to be made on or before May 1.——The Republic mine, which formerly paid $600,000 in dividends, but was sold for taxes in 1906 and bought in by the county, was today leased by the county to Richard Mulroy for two years, the lessee having an option to purchase the mine for $40,000. A royalty of 10% to be paid under the lease will apply to the purchase price. The lessee must begin work within 30 days and continue it to the expiration of the lease, unless he purchases the property before that date. W. J. Casey, Wm. Peirce, and Chas. P. Bennett, attorney of Ferry county, are understood to be associated with Mr. Mulroy. The mine is in such condition that it will require at least a month to put it in working order. The upper levels will be developed with drifts and cross-cuts before any attempt is made to operate below the 600-ft. adit level. ——Wm. M. Crummer, lessee of the Insurgent mine, has been appointed superintendent of the Pearl Con. property under the option held by the Syndicated Deep Mines Co.—— The Lone Pine workings have been unwatered to a depth of 95 ft.——The Insurgent mine continues a paying venture for the lessee, the pay-shoot continuing to yield good ore. ——Work has been resumed on the Pin Money adit by the Oversight Mining & Milling Co.——The Summit Gold & Copper Mining Co. has completed additional living quarters and will increase its force on the Railroad mine, two miles south of Laurier. Besides a large deposit of low-grade ore with an excess of iron, a streak 3 ft. wide has been encountered which assays $45 per ton in gold and copper. There is 30 ft. of ore now in sight, and the company will soon start shipping. P. O'Brien of Laurier is superintendent.

Republic, March 4.

STEVENS COUNTY.

(Special Correspondence).—The Robena Silver-Lead Mining Co., which is developing four claims that had lain idle for a number of years, reports it has recently found some good galena in the abandoned workings. Assays show an average of $40 per ton. A large quantity of ore has already been placed in bins, ready for shipment. The erection of a small concentrator is now under consideration.

Spokane, March 7.

(Special Correspondence).—The Robena Silver Mining Co. has four claims 1½ miles northeast of Bossburg. Considerable ore has been developed and shipments have been made. A concentrator is to be installed. About 7000 tons of silver-lead ore, having an average value of $21 per ton, have been blocked out. The largest body yet developed is opened by an adit 380 ft. in length. Four carloads of ore were recently shipped to the smelter. C. W. O'Connell is the manager. William R. White is president, and I. D. Nickerson secretary. The principal place of business is Spokane.——The Columbia Tungsten Co. has ten claims near Springdale, covering two distinct veins of tungsten ore. One vein is crossed near the surface by a short adit. Four men are now driving a lower adit to cross-cut the second vein. A 30-ton concentrator is projected, to be installed as soon as the money is subscribed for the purpose. ——The Cedar Canyon Smelting & Reduction Co., owning five tungsten claims, is planning for a 50-ton concentrator, to be built at the mouth of Cedar canyon for its own and custom ores.——Deer Trail camp is reported to be looking particularly bright, and over 100 men are employed, many of them being engaged in developing tungsten properties, in which the Krupp Steel Works of Essen, Germany, are reported to be interested.——The Valley Dew Mining Co. has been incorporated to work the Shiflett, Young, and Hodnett claims, north of the First Thought group.——Work is progressing on the No. 3 adit of the Trojan mine. The company will construct a wagon-road to the mine and build additional living quarters for the men as soon as the snow disappears. The mine looks well, and the company expects to be shipping soon after the middle of the year.——Work has been started on the Little Kitten group by the Mohawk Mining Co., a new organization.——The Krug Gold Mining Co. is about to drive an adit 320 ft. to cut a 4-ft. vein 217 ft. deep, and will install a 3-drill compressor plant and dynamo for lighting the mine and company buildings. The ore is said to assay about $40 per ton in gold, silver, and copper. The mine is situated north of Chewelah.—— A small force is cleaning up and getting ready to renew operations on the Walter Scott mining claim, near Northport. The vein is opened by shafts, open cuts, and a 500-ft. adit. A contract has been let for a year's work by a larger force of men, which is expected to put the mine on a paying basis.

Republic, March 6.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The smelter of the Sullivan Group Mining Co. at this place has been closed indefinitely. The cause is given by the management as the refractory character of the ores. It is well known that there has been an excess of zinc, which has greatly increased the treatment problem, and the company has been treating its own ores almost exclusively, using only a small tonnage from the First Thought mine. It is said the ores in the company's mines at Kimberly has been showing an increase in zinc as development continued, but this is not positively verified. The mines have also been closed. At the time A. I. Goodell took charge of the smelter last fall the company was thought to be in excellent condition and making considerable reductions in the cost of treating its ores, but this advantage has been offset by freezing of water, thus diminishing the power, and by the refractory quality of its ore. Rumors that the company had been forced to close for financial reasons, and that liens were to be filed on its property, are denied by the management.

Marysville, March 8.

The annual meeting of the stockholders of the British Columbia Copper Co. was held in New York recently. The year's operations were the most trying and hardest in the history of the company. In the winter of 1906-1907 the Northwest was subjected for many weeks to the most serious fuel famine ever known. When active operations were resumed, the price of copper fell so low that smelting operations were finally abandoned. In spite of this series of misfortunes, the condition of the company's affairs is perfectly satisfactory, and the ore-reserves have been increased during the last year, and the smelter is splendidly equipped. The result of the year's work shows an income of $88,155 and surplus of $176,041, and a new property, the Lone Star & Washington, has been purchased.——A new record was established at the Granby Con. smelter at Grand Forks, when 3450 tons of Phoenix ore was treated in 24 hr. in 8 furnaces.——Machinery worth $20,000 will be installed at the Bertha Con. Gold Mining Co. near Grand Forks.

The officials of the Tacoma smelter have acquired a large interest in the Eagle group of copper claims, adjoining the Japanese group near Jedway, Queen Charlotte Island. Arrangements will be made to build an aerial tramway to the beach and erect a compressor. The Eagle group, which was formerly owned by F. M. Newberry and his brother, is a property of great promise. There is a 40-ft. shaft and a 30-ft. adit, all in one. Several veins occur, one of which is 20 ft. wide. The ore is said to average 7% copper, 40 oz. silver, and $1.30 gold per ton.——The Sally mine has shipped three car-loads of ore since Jan. 1.——The January output for the Le Roi No. 2 was as follows: Josie mine shipped 2711 tons, valued at $68,592, and 142 tons of concentrate worth $2235. The Vancouver mine shipped 278 tons and received $16,298, and also $9804 for 1316 tons of zinc ore which had accumulated for several months.—— The output of the properties of the Con. Mining & Smelting Co. for the last six months has been published. The mines produced nearly a quarter of a million tons. The Centre Star group at Rossland, B. C., 87,451 tons; St. Eugene group, Moyie, B. C., 75,104 tons; the Snowshoe mine, Phoenix, B. C., 86,109 tons. The total production of the mines was about 1380 tons per day, and the amount smelted at Trail about 1116 tons per day, producing 42 tons of lead bullion worth $165 per ton, and 14.8 tons copper matte averaging $453 per ton.

Special Correspondence.

LONDON.

Mining Booms.—Cornish Mining.—Air-Cushioned Stamps.—The Chartered Company.—Reforms and Finances.

The various articles and letters in your pages relating to the 'Psychology of Mining Booms' have naturally been read with interest in this country. I should like to add a few remarks, which represent the views of many people on this side. In your issue of January 25 you printed a contribution by me, urging that the position and rank of the mining engineer should be gradually improved in such a way that his word would be taken as to the value of a mine, capitalization, and purchase price. As it is, the financiers have it all their own way in this matter, and money is extracted from the public by what are too often false pretences. Shareholders and intending shareholders are given an utterly wrong idea of mining operations. Financiers say that unless you stuff the people with all sorts of plausible stories about immediate profits, they will never subscribe for mining shares. As an example, the financiers say when inaugurating a company that a certain sum is ample and that the mine will pay within a year. Those who know the City, are perfectly aware that next year the chairman will begin his speech thus: "Owing to unexpected difficulties, etc., etc." I need not write the rest. Now to get back to my point. It seems obvious to me that while shareholders take the word of financiers and not engineers in matters of capitalization, purchase price, and general expenditure, so long will it be necessary to inaugurate booms for the purpose of raising capital. When mining operations are entirely controlled by mining engineers, booms will no longer be necessary and will die of atrophy.

The East Pool & Agar United Mines is perhaps the best managed mining company in Cornwall. It still operates on the cost-book system and pays for modern plant out of revenue, besides providing very decent dividends. The ore is troublesome stuff, containing tin, wolfram, copper, and arsenic, so that it is impossible to effect any preliminary sorting of the ore. The accounts of the company are made up every quarter. During the last quarter of 1907, a profit of over £2000 was made, and £1920 distributed in dividends. The profits were much smaller than during the earlier part of the year, owing to the drop in the price of tin. The total ore sent through the stamps was 16,007 tons, yielding 153½ tons of tin concentrate, which sold for £12,248. Arsenic brought an income of £4947, and wolfram £1252. The amount of copper in the ore is not at present very great, and is only reported every half-year. It is noteworthy that the substitution of old plant is still going on. At the present time, six new air-cushioned stamps are being erected to take the place of some of the old Cornish stamps. About a year ago two air-cushioned stamps were erected as an experiment, and the fact that six more are now being put up shows that their performance is satisfactory. These stamps are called by their makers (Holman Brothers) 'pneumatic stamps,' a name that leads many people to the idea that they are operated by compressed air. I have accordingly re-christened them air-cushioned stamps. They are operated from a crank-shaft through a connecting rod, which is connected to the stamp-stem by an air-cushioned joint. The stamp can work at a great rate and will crush twenty times as much rock as a California stamp. Naturally, such a machine requires a higher class of attendant than an ordinary stamp. It seems to me to be a machine that deserves more attention from mining engineers than it at the present receives. Another interesting point is that these new stamps are to be driven by steam-power and not by electricity. There is a large electric generating station close by which drives the Redruth & Camborne tramways, and supplies power to all sorts of industrial concerns, including the South Crofty mine. A close study of costs, however, has shown that for the new East Pool stamps the costs would be greater than if steam is used. The control and management at this mine is in the hands of Cornishmen, notably J. H. Collins, Joseph Tamblyn, and Amos Treloar.

Two weeks ago I referred to the meeting of shareholders held in London to discuss the present state of the British South Africa Co., and of the country under its control. The report of the company for the year ended March 31, 1907, together with the financial statement, have been issued this week, and the proposals of the directors for raising the necessary funds for effecting improvements in the country and its government have been submitted to shareholders. There is no doubt that the company has arrived at an important epoch in its history, and it is desirable that the present position shall be
